New England Brokers Predict Scrap Shortage in 1944; WPB Argues, "No"

Boston

• • • **Yardsmen and brokers** stress the dwindling supply of scrap and likelihood of a scarcity during the first half of 1944, at least. Such reports are not substantiated by the WPB and figures compiled by the Boston office of that agency bear out the contention that New England has done exceptionally well in the matter of scrap shipments to consuming mills, and will, it is believed, continue to do so.

The WPB's Boston office admits, however, that New England shipments to mills during the past year and a half have fallen below quotas, a fact ascribed to a growing shortage of labor in certain New England states brought about by the shortsightedness of yardsmen themselves, and not to a shortage of scrap.

Connecticut yardsmen, the Boston office says, "were right on the ball" so far as labor goes, long before the "little steel" formula came into being. Apparently they sensed Government regulation of wages. They raised wages far above the then prevailing rates and by so doing held their supply of labor to a nearly normal basis when Government regulation started. Elsewhere in New England, and especially in Massachusetts, yardsmen took no such precautions and labor shortages have resulted, according to the WPB.

From July 1 to Dec. 31, 1942, New England shipped to consuming mills 856,480 gross tons of steel scrap, whereas its quota for that period was 848,000 gross tons. From Jan. 1 to June 30, 1943, shipments were 832,467 gross tons, as against a quota of 833,000 gross tons. For the last half of 1943 the quota jumped to 947,500 gross tons. Shipments for July, August and September were 420,481 gross tons, and for October, November and December (estimated) 405,000 gross tons, making the total for the last half of 1943 approximately 825,866 gross tons.

Thus for a period of a year and a half New England shipped about 2,515,000 gross tons of scrap to consumers, down something like 113,000 gross tons from that period's quotas of 2,628,500 gross tons. In addition, 200,000 net tons of non-ferrous metal scrap were shipped, to say nothing of many tons of tin cans, rubber, paper and other waste materials.

New England automobile wreckers from February, 1942, to Dec. 31, 1943, produced and shipped 265,000 tons of iron and steel scrap and many hundred tons of non-ferrous metal scrap. Based on quotas, they were in fourth place for tonnage of scrap steel shipped in July, August, September, October and November.

o o o

Consumption Totals 55,900,000 Tons

Boston

• • • **Consumption of iron** and steel scrap in 1943 reached the record-breaking total of approximately 55,900,000 gross tons. This computation is based on actual figures of the Bureau of Mines. This total was 4 per cent greater than the previous peak of 53,807,000 gross tons consumed in 1942. It compares with the peacetime top of 38,006,000 gross tons in 1937, and is more than double the best year of the first World War, which was 26,800,000 gross tons in 1917.

This 55,900,000 tons of scrap was melted in various types of furnaces with 53,856,000 tons of pig iron almost entirely for the war effort.

The 1943 melt of 55,900,000 tons of scrap breaks down into 32,100,000 tons of "home scrap," and 23,800,000 tons of purchase or open market scrap.

From 1940 through 1943, representing the defense and war period to date, consumption of iron and steel scrap was 202,358,000 gross tons, more than the entire period of 1930 to 1937, inclusive.

The melt of scrap in 1943 represented an average of 860 pounds for every person in the United States.

Lieut. Thomas R. Allen, Jr., son of Thomas R. Allen of Continental Iron & Steel Co., New York, has been reported missing in action over Germany while piloting a Consolidated Liberator bomber. Graduated at Blytheville, Ark., on July 28, 1943, he was transferred to England last November.

•

BOSTON—Supply of production scrap continues to fall off and yards are handling comparatively little other material. A check by the Boston & Albany Railroad on yards it serves shows that rail shipments are less than 50 per cent of normal. Demand for cast in general is many thousand tons short of supply. One Boston foundry alone is in the market for 3000 tons. Supply of breakable cast has hit an all-time low level.

•

BIRMINGHAM—No pickup in demand for material is noticeable in this district. Even special foundry and electric furnace grades originating in the Birmingham switching area cannot be sold at present to Birmingham consumers.

•

CINCINNATI—The market in this area is spotty, with but a few grades in fair demand. Cast grades and rails for melting are receiving a good bit of attention from consumers, but dealers declare that the volume of business is off considerably. Some modest demand, a trifle above the market average, is indicated in industrial types of scrap and, by and large, dealers indicate that demand, so far, is being met.

•

CLEVELAND—Local buying has practically stopped, but substantial tonnages are moving to Youngstown, Warren, Farrell, and the Canton-Massillon area. Inflow to yards is poor. Some blast furnace scrap is moving locally. A railroad embargo on scrap has taken the present major consumer of turnings out of the market for an undetermined length of time.

•

PHILADELPHIA — Demand for open hearth grades has increased substantially this past week as inventories of several mills have gone down to low levels. Low phos sales continue weak and sales have been made in some instances at 75c. per ton below the ceiling price. In spite of WPB's order releasing some alloy grades for carbon steel production, no consumers have been taking the alloys permitted.

•

BUFFALO—The district's leading consumer was in an easier scrap position this week because of allocations from Michigan, Pennsylvania, and New England. This consumer has been operating on a three-week reserve for some time. Yards were busy as a result of getting 80 per cent of the district's record-breaking industrial salvage for processing before delivery to consumers. Truck loads remain negligible. Wickwire was out of the market for a week owing to a shutdown of all open hearths.

IRON AND STEEL (OTHER THAN RAILROAD) SCRAP

(All Prices Are Per Gross Ton)

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles: No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing points (cents per gross ton) are: Pittsburgh, Brackenridge, 55c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, 42c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Harrisburg, Phoenixville, Bethlehem, Kokomo, Duluth, St. Louis, 28c.; Buffalo, Claymont, 36c.; Conshohocken, 11c.; Atlanta, Birmingham, 32c.; Pittsburg, Cal., 42c.; Middletown, 14c.; Sparrow's Point, 11c.; Chicago, 84c.; Detroit, 53c.; Alabama City, 26c.; Minnequa, 22c.; Seattle, 38c. At Cincinnati, for basic open hearth grades, foundry steel and auto springs and crankshafts, deduct 80c. per ton.

PITTSBURGH basing point includes switching districts of Bessemer, Homestead, Duquesne, Munhall and McKeesport. Cincinnati basing point includes Newport, Ky., switching district. St. Louis includes switching districts of Granite City, East St. Louis, Madison, Ill. San Francisco includes switching districts of S. San Francisco, Niles and Oakmont, Cal. Claymont, Del., includes the switching point of Chester, Pa. Chicago includes Gary, Ind., switching district.

MAXIMUM SHIPPING POINT PRICE—Where shipment is by rail or vessel, or by combination of rail and vessel, the scrap is at its shipping point when placed f.o.b. railroad or f.a.s. vessel. In such cases, the maximum shipping point prices shall be: (a) For shipping points located within a basing point, the price listed in the table above for the scrap at the basing point in which the shipping point is located, minus the lowest established switching charge for scrap within the basing point and (b) for shipping points located outside the basing point, the price in table above at the most favorable basing point minus the lowest transportation charge by rail or water or combination thereof. In lieu of dock charge add 75c. a ton, but 50c. if moved by deck scow or railroad lighter. Shipping by motor vehicle: The scrap is at its shipping point when loaded. For shipping points located within basing points take price listed in table minus applicable switching charge. If located outside a basing point, the price at the most favorable basing point minus lowest established charge for transporting by common carrier. If no established transportation rate exists, the customary costs are deducted. Published dock charges prevail. If unpublished include 75c.; at Memphis, 50c.; Great Lakes ports, $1; New England, $1.25. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding grade or grades of prepared scrap. In no case, however, shall electric furnace and foundry grades be used as the "corresponding grade or grades of prepared scrap." Converter may charge $2.50 per ton on consumer-owned unprepared remote scrap (see order). A preparation-in-transit charge for allocated unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced—$2; 75 to 85% Fe—$4; under 75% Fe—$8 per ton. Mill scale of 65% or more Fe—$8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1 per cent oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5 per cent oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c.

Magnesium, ingot	20.50	20.50	20.50	22.50
Antimony (Asiatic), N. Y.	16.50	16.50	16.50	16.50

The various basing points for finished and semi-finished steel are listed in the detailed price tables, pages 141-153.

Composite Prices . . .

Starting with the issue of April 22, 1943, the weighted finished steel price index was revised for the years 1941, 1942 and 1943. See explanation of the change on page 90 of the April 22, 1943, issue.

	FINISHED STEEL	PIG IRON	SCRAP STEEL
Jan. 25, 1944	2.25513c. a Lb.	$23.61 a Gross Ton	$19.17 a Gross Ton
One week ago	2.25513c. a Lb.	$23.61 a Gross Ton	$19.17 a Gross Ton
One month ago	2.25513c. a Lb.	$23.61 a Gross Ton	$19.17 a Gross Ton
One year ago	2.26190c. a Lb.	$23.61 a Gross Ton	$19.17 a Gross Ton

	HIGH	LOW	HIGH	LOW	HIGH	LOW
1943	2.25513c.,	2.25513c.,	$23.61	$23.61	$19.17	$19.17
1942	2.26190c.,	2.26190c.,	23.61	23.61	19.17	19.17
1941	2.43078c.,	2.43078c.,	$23.61, Mar. 20	$23.45, Jan. 2	$22.00, Jan. 7	$19.17, Apr. 10

1929	2.31773c., May 28	2.26498c., Oct. 29	18.71, May 14	18.21, Dec. 17	17.58, Jan. 29	14.08, Dec. 3

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto, Ohio; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.; Sheffield Steel Corp. $2.55 St. Louis.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo, Colo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—Sheffield Steel Corp. $2.75 St. Louis; W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery in U. S. except Texas and Oklahoma may use Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. when shipped outside Alabama, Mississippi, Louisiana, Georgia, Florida, Tennessee, Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base granted on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base granted on Kokomo, Ind., product; Superior Sheet Steel Co. granted Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1999 lb.; strip, extras on all quantities; bars, 1500 to 39,999 lb.; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 to 39,999 lb. (15) 1000 to 39,999 lb. (16) 1500 to 39,999 lb. (17) 2000 to 39,999 lb. (18) 3500 to 39,999 lb.

(a) Philadelphia: Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

CAST IRON WATER PIPE

Per Net Ton

6-in. and larger, del'd Chicago	$54.80
6-in. and larger, del'd New York	52.20
6-in. and larger, Birmingham	46.00
6-in. and larger f.o.b. cars, San Francisco or Los Angeles	69.40
6-in. and larger f.o.b. cars, Seattle	71.20

Class "A" and gas pipe, $3 extra; 4-in. pipe is $3 a ton above 6-in. Prices shown are for lots of less than 200 tons. For 200 tons or over, 6-in. and larger is $45 at Birmingham and $53.80 delivered Chicago, $59.40 at San Francisco and Los Angeles, and $70.20 at Seattle. Delivered prices do not reflect new 3 per cent tax on freight rates.

LAKE SUPERIOR ORES

(51.50% Fe, Natural Content, Delivered Lower Lake Ports)*

	Per Gross Ton
Old range, bessemer, 51.50	$4.75
Old range, non-bessemer, 51.50	4.60
Mesaba, bessemer, 51.50	4.60
Mesaba, non-bessemer, 51.50	4.45
High phosphorus, 51.50	4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

PRICES

SEMI-FINISHED STEEL

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Steel

Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton	54.00

Shell Steel

	Per Gross Ton
3 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleveland, Youngstown and Birmingham.

Prices delivered Detroit are $2.00 higher; E. Michigan, $3 higher.

Note: The above base prices apply on lots of 1000 tons of a size and section to which are to be added extras for chemical requirements, cutting, or quantity.

Sheet Bars

Pittsburgh, Chicago, Cleveland, Youngstown, Buffalo, Canton, Sparrows Point, Md.

	Per Gross Ton
Open hearth or bessemer	$34.00

Skelp

Pittsburgh, Chicago, Youngstown, Coatesville, Pa., Sparrows Point, Md.

	Per Lb.
Grooved, universal and sheared	1.90c.

Wire Rods

(*No. 5 to 9/32 in.*)

	Per Lb.
Pittsburgh, Chicago, Cleveland	2.00c.
Worcester, Mass.	2.10c.
Birmingham	2.00c.
San Francisco	2.50c.
Galveston	2.25c.

9/32 in. to 47/64 in., 0.15c. a lb. higher. Quantity extras apply.

TOOL STEEL

(*F.o.b. Pittsburgh, Bethlehem, Syracuse*)

	Base per lb.
High speed	67c.
Straight molybdenum	54c.
Tungsten-molybdenum	57½c.
High-carbon-chromium	43c.
Oil hardening	24c.
Special carbon	22c.
Extra carbon	18c.
Regular carbon	14c.

Warehouse prices east of Mississippi are 2c. a lb. higher; west of Mississippi 3c. higher.

CORROSION AND HEAT-RESISTING STEEL

(*Per lb. base price, f.o.b. Pittsburgh*)

Chromium-Nickel Alloys

	No. 304	No. 302
Forging billets	21.25c.	20.40c.

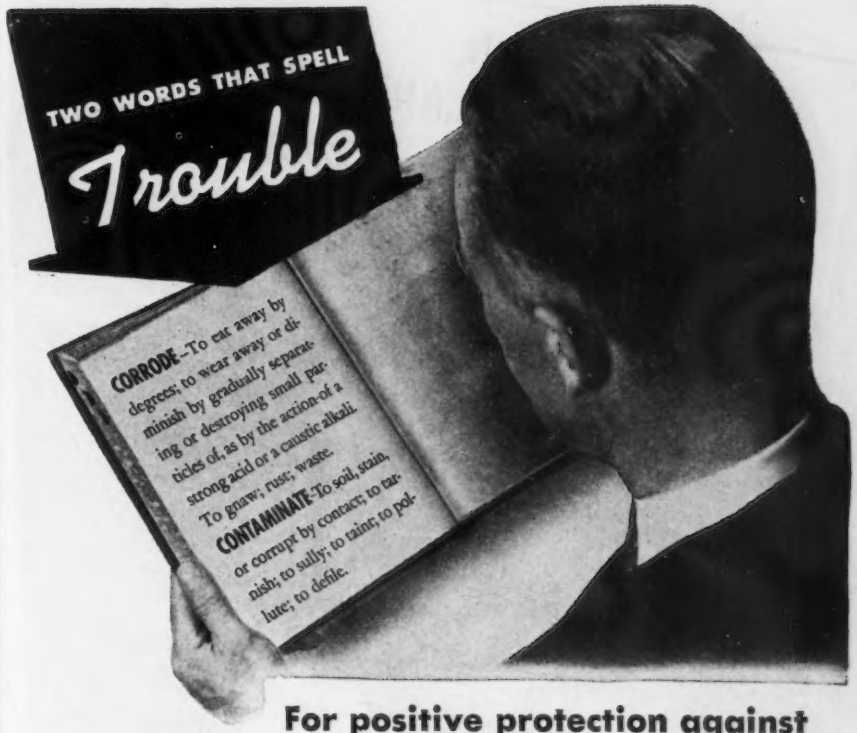
Chromium-Nickel Clad Steel (20%)

	No. 304
Plates	18.00c.*
Sheets	19.00c.

*Includes annealing and pickling.



For positive protection against

CORROSION & CONTAMINATION

Amercoat Plastic Coatings!

Delays, expense, waste . . . that's the price paid in many a business when corrosion attacks critical materials and equipment, or contaminates vital war and food supplies. These costly hazards are eliminated by Amercoat, the approved thermoplastic coating for metal, wood or concrete. Amercoat provides *dual* protection. It protects tanks, tank cars, machinery, buildings, floors, walls, equipment and containers of many types from corrosion by acids, alkalies, chemicals, brine, water, air and other corrosive agents. Amercoat also protects foods, beverages, gasoline, oil and many other essential supplies from contamination by the products of corrosion.

Amercoat is odorless, tasteless, chemically inert. It adheres tightly, is hard and impenetrable. Resists abrasion, withstands moderate expansion, contraction and vibration without checking or cracking. Dielectric; low water absorption.

If you have a corrosion or contamination problem, get the facts about Amercoat. Write for booklet describing its many uses.

EASY TO APPLY

Amercoat is quickly sprayed or brushed on metal, wood or concrete

PARTIAL LIST OF INDUSTRIES USING AMERCOAT

Canadian Dist.: Gunite & Waterproofing, Ltd., Montreal, Quebec.

HOW AN AUTOMOBILE PLANT CONVERTED *from Cars to Cartridges*

HERE'S another plant conversion in which A-F Conveyor Engineers cooperated with a deep feeling of pride and achievement.

To convey the component cartridge parts in tote boxes to remote restricted areas, an A-F Overload Conveyor System, over 12,000 feet in length, was installed. A similar, but shorter, A-F Conveyor System also conveys cartridge links.

This "Scientifically Planned" A-F Overhead Conveyor System frees valuable floor space and aisleways for other purposes, while constantly supplying employees with parts "from the air" in an endless stream.

Equipped with 7 synchronized caterpillar drives, such a conveyor system can be increased to almost indefinite lengths by adding additional drives, all operated from a central station.

★ WHEN *YOUR PLANT CONVERTS BACK TO* PEACE-TIME PRODUCTION—*WRITE A-F*

Since 1901, our engineers have helped hundreds of leading plants to convert to war, then back to the production of their regular or new peace-time lines. Let us help you obtain peak post-war production quickly and efficiently with an A-F Scientifically Planned Conveyor System and A-F Metal Products Cleaning and Finishing Equipment. Write today.

THE ALVEY-FERGUSON COMPANY, 708 Disney St., Cincinnati 9, Ohio

Wrought Iron (Same as Above)		
2 in.	33½	15½
2½ to 4 in.	39	22½
4½ to 6 in.	37½	21

On butt weld and lap weld steel pipe jobbers are granted a discount of 5%. On less-than-carload shipments prices are determined by adding 25 and 30% and the carload freight rate to the base card.

F.o.b. Gary prices are two points lower discount or $4 a ton higher than Pittsburgh or Lorain on lap weld and one point lower discount, or $2 a ton higher on all butt weld.

Try This For Ten Seconds

Just take a couple of pencils right now and try to hold them in perfect alignment without touching each other while you count 10.

This will quickly show you why a good flexible coupling is essential when connecting driving and driven shafts to prevent excessive bearing wear due to unavoidable misalignment.

Ajax Flexible Couplings have been doing this job for 20 years. They do it without lubrication because of their rubber bushed, graphited-bronze bearings and interlocking drive studs. Write for the facts on Ajax Flexible Couplings.

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable.

(2) Price shown is for low-phosphorous iron; high-phosphorous sells for $28.50 at the furnace.

(3) Eastern Gas & Fuel Associates, Boston, is permitted to sell pig iron produced by its selling company. Effective Feb. 1, 1944, Mystic Iron will be sold without the above OPA price relief grant of $2 per ton.

(4) E. & G. Brooke Co. permitted to charge $1.00 per ton extra.

(5) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 per cent to 2.25 per cent); phosphorous differentials, a reduction of 38c. per ton for phosphorous content of 0.70 per cent and over; manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. For ton lots f.o.b. shipping point, in cents per lb.

Copper, electrolytic, 150 and 200 mesh	21½ to 23½c.
Copper, reduced, 150 and 200 mesh	20½ to 25½c.
Iron, commercial, 100 and 200 mesh, 96 + % Fe	13½ to 15c.
Iron, crushed, 200 mesh and finer, 90 + % Fe	4c.
Iron, hydrogen reduced, 300 mesh and finer, 98½ + % Fe	63c.
Iron, electrolytic, unannealed, coarser than 300 mesh, 99 + % Fe	30 to 33c.
Iron, electrolytic, annealed minus 100 mesh, 99 + % Fe	42c.
Iron, carbonyl, 300 mesh and finer, 98-99.8 + % Fe	90c.
Aluminum, 100 and 200 mesh	*23 to 27c.
Antimony, 100 mesh	20.6c.
Cadmium, 100 mesh	$1
Chromium, 150 mesh	$1.03
Lead, 100, 200 & 300 mesh, 11½ to 12½c.	
Manganese, 150 mesh	51c.
Nickel, 150 mesh	51½c.
Solder powder, 100 mesh, 8½c. plus metal	
Tin, 100 mesh	58¾c.
Tungsten metal powder, 98%-99%, any quantity, per lb.	$2.60
Molybdenum powder, 99%, in 200-lb. kegs, f.o.b. York, Pa., per lb.	$2.60
Under 100 lb.	$3.00

*Freight allowed east of Mississippi.

BOILER TUBES

Seamless Steel and Lap Weld Commercial Boiler Tubes and Locomotive Tubes, Minimum Wall. Net base prices per 100 ft. f.o.b. Pittsburgh, in carload lots.

PRICES

BOLTS, NUTS, RIVETS, SET SCREWS

Bolts and Nuts
(F.o.b. Pittsburgh, Cleveland, Birmingham or Chicago)

Machine and Carriage Bolts:

	Per Cent Off List
½ in. & smaller x 6 in. & shorter	65½
9/16 & ⅝ in. x 6 in. & shorter	63½
¾ to 1 in. x 6 in. & shorter	61
1⅛ in. and larger, all length	59
All diameters over 6 in. long	59
Lag, all sizes	62
Plow bolts	65

Nuts, Cold Punched or Hot Pressed:
(Hexagon or Square)

½ in. and smaller	62
9/16 to 1 in. inclusive	59
1⅛ to 1½ in. inclusive	57
1⅝ in. and larger	56

On above bolts and nuts, excepting plow bolts, additional allowance of 10 per cent for full container quantities. There is an additional 5 per cent allowance for carload shipments.

Semi-Fin. Hexagon Nuts	U.S.S.	S.A.E.
7/16 in. and smaller	..	64
½ in. and smaller	62	..
½ in. through 1 in.	..	60
9/16 to 1 in.	59	..
1⅛ in. through 1½ in.	57	58
1⅝ in. and larger	56	..

In full container lots, 10 per cent additional discount.

Stove Bolts

Packages, nuts loose	71 and 10
In packages, with nuts attached	71
In bulk	80

On stove bolts freight allowed up to 65c. per 100 lb. based on Cleveland, Chicago, New York on lots of 200 lb. or over.

Large Rivets *(½ in. and larger)*

	Base per 100 lb.
F.o.b. Pittsburgh, Cleveland, Chicago, Birmingham	$3.75

Small Rivets *(7/16 in. and smaller)*

	Per Cent Off List
F.o.b. Pittsburgh, Cleveland, Chicago, Birmingham	65 and 5

Cap and Set Screws

	Per Cent Off List
Upset full fin. hexagon head cap screws, coarse or fine thread, up to and incl. 1 in. x 6 in.	64
Upset set screws, cup and oval points	71
Milled studs	46
Flat head cap screws, listed sizes	36
Fillister head cap, listed sizes	51

Freight allowed up to 65c. per 100 lb. based on Cleveland, Chicago or New York on lots of 200 lb. or over.

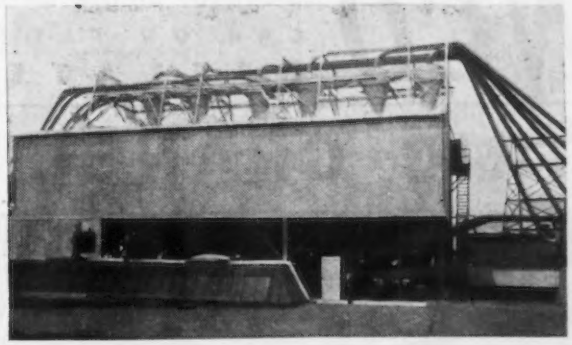
RAILS, TRACK SUPPLIES
(F.o.b. Mill)

Standard rails, heavier than 60 lb., No. 1 O.H., gross ton	$40.00
Angles bars, 100 lb.	2.70
California Ports	$3.15
(F.o.b. Basing Points)	*Per Gross Ton*
Light rails (from billets)	$40.00
Light rails (from rail steel)	39.00
	Base per Lb.
Cut spikes	3.00c.
Screw spikes	5.15c.
Tie plates, steel	2.15c.
Tie plates, Pacific Coast	2.30c.
Track bolts	4.75c.
Track bolts, heat treated, to railroads	5.00c.
Track bolts, jobbers discount	63-5

Basing points, light rails, Pittsburgh, Chicago, Birmingham: spikes and tie plates—Pittsburgh, Chicago, Portsmouth, Ohio, Weirton, W. Va., St. Louis, Kansas City, Minnequa, Colo., Birmingham and Pacific Coast ports: tie plates alone—Steelton, Pa., Buffalo. Spikes alone—Youngstown, Lebanon, Pa., Richmond, Oregon and Washington ports, add 25c.

ROOFING TERNE PLATE
(F.o.b. Pittsburgh, 112 Sheets)

	20x14 in.	20x28 in.
8-lb. coating I.C.	$6.00	$12.00
15-lb. coating I.C.	7.00	14.00
20-lb. coating I.C.	7.50	15.00



CORK STORAGE BINS, 18 hoppers of No. 10 ga. steel, kept weather proof by a 54'x81'x30' corrugated enclosure . . . System, including structural supports and conveyor ducts designed, fabricated and erected by Brandt.

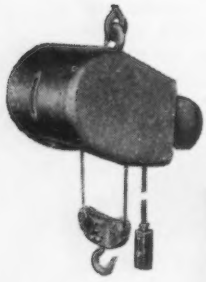
HEAT-TREATED STEEL GRIT

CONCO 3-Motor Single Girder CAB OR FLOOR OPERATED ELECTRIC CRANE . . .

● **Available in capacities of one through five tons for floor or cab operation. Simply, ruggedly designed for low first cost and maintenance. Used with Low Headroom Type Hoist, provides for maximum space coverage horizontally and vertically. Effective in even a minimum space. Write for Bulletin 2000.**



Write for Bulletin 26000 describing the Torpedo Hoist shown. Three capacities 250 lb. — $139.50, 500 lb. — $149.50, 1000 lb. — $159.50. Heavily, simply built, with Push Button Control. Outstanding in CONCO'S complete line of hand-powered and electric Cranes, Hoists, Trolleys.

CONCO ENGINEERING WORKS

Div. of H. D. Conkey & Co. — 15 Grove St. — Mendota, Ill.

Builders Of Conco Torpedo Electric Hoist

PRICES

Ferromanganese

78-82% manganese, maximum contract base price per gross ton, lump size, f.o.b. car at Baltimore, Philadelphia, New York, Birmingham, Rockdale, Rockwood, Tenn.

Carload lots (bulk)	$135.00
Ton lots (packed)	141.00
Less ton lots (packed)	148.50

Premium, $1.70 for each 1% above 82% Mn; penalty, $1.70 for each 1% below 78%.

Electrolytic Manganese

99.9% manganese, maximum base contract price per lb. of metal, bulk, f.o.b. shipping point, with freight allowed to destination. Size 1" x D.

	Eastern Zone	Central Zone	Western Zone
Carload lots	37.60c.	37.85c.	38.15c.
l.c.l. lots	39.60c.	38.60c.	40.65c.

Spiegeleisen

Maximum base contract prices, per gross ton, lump, f.o.b. Palmerton, Pa.

	16-19% Mn 1% max. Si	19-21% Mn 1% max. Si	26-28% Mn 1% max. Si
Carloads	$35.00	$36.00	$49.50
Less ton*	47.50	48.50	62.00

Electric Ferrosilicon

OPA maximum base price cents per lb. contained Si, lump size in carlots, f.o.b. shipping point with freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
50% silicon	6.65c.	7.10c.	7.25c.
75% silicon	8.05c.	8.20c.	8.75c.

Spot sales 45c. per lb. higher or 50% Si; 30c. for 75% Si. For extras and premiums see MPR 405.

Silvery Iron

(Per Gross Ton, base 6.00 to 6.50 Si)

F.o.b. Jackson, Ohio	$29.50*
Buffalo	30.75*

For each additional 0.50% silicon add $1 a ton. For each 0.50% manganese over 1% add 50c. a ton. Add $1 a ton for 0.75% phosphorous or over.

*Official OPA price established June 24, 1941.

Bessemer Ferrosilicon

Prices are $1 a ton above silvery iron quotations of comparable analysis.

Silicon Metal

OPA maximum base price per lb. of contained Si, lump size, f.o.b. shipping point with freight allowed to destination, for l.c.l. above 2000 lb., packed.

	Eastern Zone	Central Zone	Western Zone
96% Si, 2% Fe	13.10c.	13.55c.	16.50c.
97% Si, 1% Fe	13.45c.	13.90c.	16.80c.

Ferrosilicon Briquets

OPA maximum base price per lb. of briquet, bulk, f.o.b. shipping point with freight allowed to destination. Approximately 40% silicon.

	Eastern Zone	Central Zone	Western Zone
Car lots	3.35c.	3.50c.	3.65c.

Spot prices ¼c. higher per lb. of briquet. For premiums and extras see MPR 405.

Silicomanganese

(Per gross ton, delivered, carloads, bulk)

3.00 carbon	$120.00*
2.50 carbon	125.00*
2.00 carbon	130.00*
1.00 carbon	140.00*
Briquets, contract, basis carlots, bulk freight allowed, per lb.	5.80c.†
Packed	6.05c.†
Less ton lots	6.55c.†

*Spot prices are $5 per ton higher.
†Spot prices ¼c. higher.

Ferrochrome

(65-72% Cr, 2% max. Si)

OPA maximum base contract prices per lb. of contained Cr, lump size in carlots, f.o.b. shipping point, freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
0.03% carbon	25.00c.	25.40c.	26.00c.
0.06% carbon	23.00c.	23.40c.	24.00c.
0.10% carbon	22.50c.	22.90c.	23.50c.
1.00% carbon	20.50c.	20.90c.	21.50c.
2.00% carbon	19.50c.	19.90c.	20.50c.

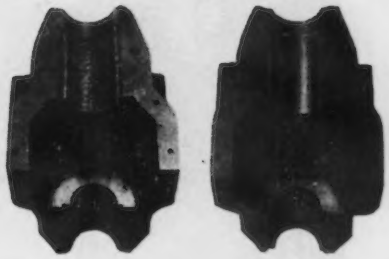
Spot prices are ¼c. higher per lb. contained Cr. For extras and premiums see MPR 407.

Other Ferroalloys

Ferrotungsten, Standard grade, lump or ¼X down, packed, f.o.b. producer's plant at Niagara Falls, New York, Washington, Pa., York, Pa., per lb. contained tungsten. 10,000 lb. or more	$1.90
Ferrovanadium, 30-35%, contract basis, f.o.b. producer's plant, usual freight allowances, any quantity, per lb. contained vanadium.	
Open Hearth	$2.70
Crucible	$2.80
Primos	$2.90
Cobalt, 97% min., keg packed, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. of cobalt metal	$1.50
Vanadium pentoxide, 88%-92% V_2O_5 technical grade, contract basis, any quantity, per lb. contained V_2O_5	$1.10
Ferroborom, contract basis, 17.50% borom minimum, f.o.b. Niagara Falls, carlots, per lb. alloy	$1.20
Ton lots	$1.25
Silcaz No. 3, contract basis, f.o.b. Niagara Falls, all quantities, per lb. of alloy	23c.
Silvaz No. 3, contract basis, f.o.b. Niagara Falls, all quantities, per lb. of alloy	40c.
Grainal, f.o.b. Bridgeville, Pa., freight allowed 100 lb. and over, maximum based on rate to St. Louis, per lb.	45c.
Bortam, f.o.b. Niagara Falls	
Ton lots, per lb.	45c.
Less ton lots, per lb.	50c.
Borosil, 3% to 4% boron, 40 to 45% silicon, f.o.b. Philo, Ohio, per lb. contained boron	$6.25
Ferrocolumbium, 50% to 60%, f.o.b. Niagara Falls, ton lots, per lb. contained columbium	$2.25
Less ton lots	$2.30
Ferrotitanium, 40%-45%, f.o.b. Niagara Falls, N. Y., ton lots, per lb. contained titanium	$1.23
Less ton lots	$1.25
Ferrotitanium, 20%-25%, 0.10 C max., ton lots, per lb. contained titanium	$1.35
Less ton lots	$1.40
High-carbon ferrotitanium, 15%-20%, 6%-8% carbon, contract basis, f.o.b. Niagara Falls, N. Y., freight allowed East of Mississippi River, North of Baltimore and St. Louis, per gross ton	$142.50
3%-5% carbon	$157.50
Ferrophosphorus, 18% electric or blast furnace, f.o.b. Anniston, Ala., carlots, with $3 unitage freight equaled with Rockdale, Tenn., per gross ton	$58.50
Ferrophosphorus, electrolytic 23-26%, carlots, f.o.b. Monsanto (Siglo), Tenn., $3 unitage freight equalized with Nashville, per gross ton	$75.00
Ferromolybdenum, 55-75 per cent, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum	95c.
Calcium molybdate, 40%-45%, contract basis, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum	80c.
Molybdenum oxide briquettes, 48%-52% Mo, f.o.b. Langeloth, Pa., per lb. contained Mo	80c.
Molybdenum oxide, in cans, f.o.b. Langeloth and Washington, Pa., per lb. contained Mo	80c.
Zirconium, 35-40%, contract basis, carloads in bulk or package, per lb. of alloy	15c.
Less ton lots	16c.
Zirconium, 12-15%, contract basis, carlots, bulk, per gross ton	$102.50
Packed	$107.50
Less ton lots	$112.50
Alsifer (approx. 20% Al, 40% Si and 40% Fe), contract basis, f.o.b. Niagara Falls, per lb.	7.50c.
Ton lots	8c.
Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.	
Car lots	8.75c.
Ton lots	9.25c.
Less ton lots	9.75c.

Yes

Our customers make machinable Arc Welds on CAST IRON



Before machining. After Machining. After being welded with PHILLIPS "600" Electrode this cast iron housing was machined through the fusion zone.

This book tells what procedure is best for *your* cast iron welding.

Send for your copy TODAY

PHILLIPS "600" Electrode, a non-ferrous, flux-coated rod, produces deposits that are of the color of cast iron and are *fully machinable through the line of fusion.* It can be used in all positions with A.C. or D.C. and maintains a steady and quiet arc without excessive spatter. This electrode is salvaging many valuable castings daily in hundreds of foundries and machine shops. Complete procedure information is contained in our 12-page book on "4 Ways to Salvage, Reclaim and Conserve Iron Castings by Electric Arc Welding." A copy is yours for the asking.

The Overhanging Surplus

CAPITAL goods manufacturers in our country are faced with the problem of doing postwar business in the face of a probable carryover of government owned equipment amounting to several billion dollars. In addition, they face the hurdle of privately bought and owned equipment inventories tremendously swollen by war manufacturing activity.

Plans are being sought whereby the impact of this carryover may be lessened, particularly with regard to the government owned share of it. Some of these plans contemplate setting up Soviet, Chinese and other credits so that these countries could take over a large part of our unwanted machinery which they themselves will need for reconstruction of domestic economies. In return we would take back raw materials not obtainable here and other products which would not compete seriously with American labor.

Other plans now being considered by Congress and others contemplate freezing the competing surplus for a period which would allow our manufacturers time for conversion and others contemplate setting up regulations which would restrict the flow of this equipment from government to private ownership in a way least likely to disrupt postwar activity and employment. Extreme measures also have been suggested, such as dumping this equipment in the ocean or remelting it for scrap.

No doubt something will come out of all of this thinking and talking when the time comes. But to my way of thinking, the time is now and the place is at home.

The difference is between the expression "God help us," which means FDR and Congress and "God help those who help themselves," which means us.

Why depend on these outside agencies, terrestrial and celestial, when the remedy is largely within our own hands?

By this time we should have learned that the most powerful factor which adds to the scrap pile of capital equipment is obsolescence.

The best way to put a competing machine on the scrap pile, whether it is one of your own make or that of a competitor is to produce something decidedly better. Government cannot do that for you.

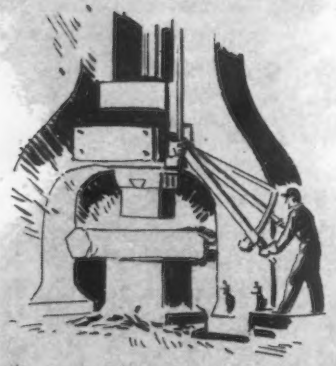
With the advances in design and metallurgical techniques which have been promoted by the war, there is no excuse for anyone offering a "just as good" product to the postwar market. You could not make a living at it if you tried. A "just as good world" is not what the American people want.

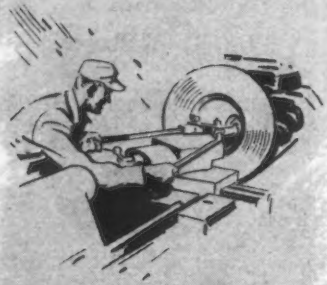
If you will get busy and put into your product the improvements that have been made available during the past two or three years, during which peace time redesign has stood still because of the preference of war for existing products, you will not have to worry much about this overhanging surplus.

It will have been, as the saying goes, "spurlos versank."

Design—

For Workability With Inland Steel





Steel offers designers and manufacturers the maximum in workability. It can be formed and fabricated by all practical production methods, keeping shop costs down. It can be formed either hot or cold. It can be easily spun or extruded into many useful shapes. Steel can be deep drawn to such extremes as in the manufacture of steel cartridge cases. It can be machined, sheared, bent, seamed, welded, and brazed. And steel is available in extreme ranges of sizes and shapes, and chemical analyses; this offers a wide scope in the design of parts, and also simplifies shop procedure, reducing wastage to the minimum.

For half a century Inland has been studying the needs of industry, working with designers and production men, to make steel more useful—to give it the workability that simplifies production and assures economical fabrication. From such close contact with field problems, Inland has given industry Ledloy, the lead bearing, faster machining steel—Hi-Steel, the low alloy, high strength steel of exceptional workability—Form-Cote, the galvanized sheet which withstands severe forming—Paint-Tite, the specially treated galvanized sheet to which paint and enamel readily adhere—and many other kinds of steel that offer numerous advantages to the designer, the production man and the consumer.

Inland engineers and metallurgists are at your service to help you design, select steel, and fabricate products for today or for the post-war period.

NEWS FRONT

► Although official quarters have been mum, continued availability to the United Nations of Bolivia's tin on the present scale has been touch and go since the coup d'etat.

Not even severance of Axis relations by Argentina has squelched the constant threat to non-ferrous metal imports to this country from South American nations.

► Carbon refractories for blast furnaces, used extensively in Europe, have never been used in the U. S. However, interest in this usage is increasing here with the realization that long economical performance out-weighs high initial cost.

Machine parts and highly finished tools can be dipped in ethylcellulose plastic, which protects them against the severest of handling and corrosive conditions. The parts can be stripped by slitting and peeling.

Boron introduced into the coating of monel welding electrodes appears to behave as a flux, permitting thorough binding between the monel and cast iron, giving an excellent weld.

► On Feb. 1, the Bethlehem-Hingham Yard eliminated its 11 p.m. to 7 a.m. shift; 10,000 workers will be discharged.

► A noticeable segment of opinion in the National Automobile Dealers Association leans toward state licensing of factories or factory representatives as a means of protecting retail outlets. Such legislation would, of course, apply to many fields beyond the automotive industry.

Auto dealers have a full-fledged campaign under way in Washington to assure that they will be the channels through which surplus Army automotive goods will flow after the war.

► The fusing together of Lend-Lease and Office of Economic Warfare into F. E. A., under the direction of Leo Crowley, has resulted in a great deal of turmoil. The flood of resignations has been very great and the top-side absentee management has done little to cope with inter-departmental friction.

However, exporters are more optimistic about this set-up than about any of the predecessors. About 3000 export licenses are coming out of Washington every day. And, the percentage of Lend-Lease to total exports is beginning to fall off.

► One authoritative British magazine commenting on the slow progress of troops in Italy says, "the truth is that since it got away from desert conditions our army has been undeniably sticky".

German rocket-firing aircraft are slowed 50 to 70 miles an hour in speed due to wind resistance on projectiles and carrying frames. The Germans, however, seem satisfied as they are using more and more rockets, and even employing them for night interception.

► Despite extensive publicity of a year ago that defective steel caused ship failures, the failures have continued. Representative Magnuson claims constructional defects are at fault, while Admiral Vickery states that improper loading is the culprit.

► To replace ore carriers sunk by submarines, Bethlehem Steel Co. is building four larger and faster ships. Those lost carried 20,000 tons at 11 knots top speed, while the new ones will carry 24,000 tons at 16 knots.

Because of equipment shortages, Bethlehem has done little to improve Venezuelan ore properties during 1943, but this year expects to carry out extensive improvements as materials and equipment become more readily available.

► The Budd Mfg. Co. all-stainless steel airplane will have a regular crew of three, but can be handled by two men. The craft will carry 6 tons of cargo about 700 miles. Cargo space measures about 25x8x8 ft.

Budd production will soon be about three daily. The Navy will acquire the first 25. The Rubber Development Corp. expects to get two in March for jungle freight routes in Brazil and Bolivia.

► OPA, after assurances by the War Department that its trial production contract for axles from the Timken-Detroit Axle Co. would not encourage inflationary tendencies, released the company from price control. Recently Timken sued the Washington Post for allegedly libelous statements in an article on renegotiation.

Isothermal Quench Baths

By HAROLD J. BABCOCK
Research Engineer,
Ajax Electric Co., Inc.,
Philadelphia

o o o

IN various technical publications there have appeared, during the past 10 years, an increasing number of articles giving information on various studies of the effect of time and temperature on the transformation of austenite in carbon and alloy steels when cooled (quenched) to various sub-critical temperatures. The procedure in these studies was first described in 1932 by E. C. Bain and E. S. Davenport of the U. S. Steel Corp. The data presented in the form of "S" curves or Time Temperature Transformation (TTT) curves are of value in determining the rate of cooling and the time required to obtain a desired structure as well as the temperature at which these structures are obtained.

But all these articles are based on work done under conditions of the metallurgical laboratory. It is the purpose of this article to point out in relatively non-technical language, some of the fundamentals of this procedure which is known as isothermal transformation of austenitized carbon and carbon-alloy steels. The data now available in the form of TTT curves form a valuable guide to practical methods to improve the physical properties of commercial steel products. The result of their application will be illustrated by description of equipment for treating steel by this method. The success of their application depends upon the use of a molten salt quenching bath capable of cooling steel at a high rate while the bath is maintained constantly at selected temperatures in the range of 450 to 1350 deg. F.

The heat treater, the metallurgist and others concerned with the heat treatment of steel are quick to adapt to their commercial need new methods that offer to improve its properties. Ever since iron was first smelted and formed into useful articles, the process of improving its physical properties has depended upon the development of new procedures. Thus alloying of iron with carbon, then with various agents as silicon, manganese, nickel, chromium, molybdenum, etc. provided the present steels. It has been learned that the chemical content of the steel, the mechanical work done on it and the maximum cross-sectional area influence the physical properties that are imparted to it by any given heat treatment. But, fundamentally, the whole process of heat treatment of carbon steels depends upon the rate at which the steel is cooled from temperatures above its critical points to room temperature.

The time honored blacksmith, with forge fire and water cask, knew that hot steel quenched in water was made hard and brittle. He knew also, that this hardened steel if gently heated to "straw temper" lost its brittleness, yet was hard and tough enough "to hold an edge" when sharpened. The modern heat treater has refined the method of heating and uses brine, and oil as well as water for the quench. The quenching procedure involves not

Applied to Commercial Practice

. . . Time-temperature transformation curves can be invaluable aids in improving physical properties of steel products. In this, the first part of a two-part article, the author compares the information obtainable from equilibrium diagrams and TTT curves. Isothermal transformation curves of several carbon and alloy steels are also examined.

merely immersion, but manual or mechanical movement of the piece in the liquid during cooling or agitation of the quench bath liquid by mechanical devices or the use of fixtures through which jets of the fluid are forced against the pieces being quenched. All such modifications are for the purpose of controlling the rate of cooling of the steel being treated.

Quench and Temper Method

Prior to 1930, the interpretation placed upon the change in structure that occurs during the cooling of steel was expressed in equilibrium diagrams. A conventional diagram to show the relationship between cooling rate, and structure is shown in Fig 1.[15] It assumes that the steel has been heated at a temperature just high enough to cause the various components such as carbon, carbides, etc. to go into solution in the iron forming stable austenite. If the steel is then quenched with increasing rates of cooling, the austenite is transformed to structures described progressively as primary pearlite, sorbite, and troostite, respectively. It will be noted that, as the cooling rate increases, the temperature of transformation drops suddenly and the product formed is martensite. This is the critical cooling rate. It is a rate rapid enough to prevent any transformation to higher temperature structures, but slow enough to prevent the retention of untransformed austenite. If the steel is cooled at or above the critical rate, thus forming martensite, the hardest structure is produced. Any rate of cooling slower than this produces progressively softer structures which are tougher and more ductile.

It is also well known that when fully hardened steel is reheated to temperatures above 350 deg. F, the martensite is transformed to structures that are progressively softer and tougher. This reheating procedure is referred to as tempering (drawing). The temperature and time used in this operation determine the type of structure produced and the products are designated progressively as secondary troostite, sorbite and pearlite, respectively.

Those familiar with heat treating practice will recognize such procedure as the conventional "quench and temper method" universally applied to impart desired conditions of hardness and obtain physical properties suitable to the use required of the steel. There are many factors influencing the results of this treatment such as grain size, per cent of carbon and of metallic alloying elements and the chemical state of the alloying components.

Under practical conditions information obtained from the equilibrium diagram has certain limitations due to the fact that operations normal to heat treatment involve continuously varying factors of time and temperature. The conditions presented in the diagram are fixed, that is, equilibrium is assumed. Consequently the influence of time and of temperature could not be evaluated in terms of their effect upon structure during the continuous cooling of steel.

At the present time, thanks to the

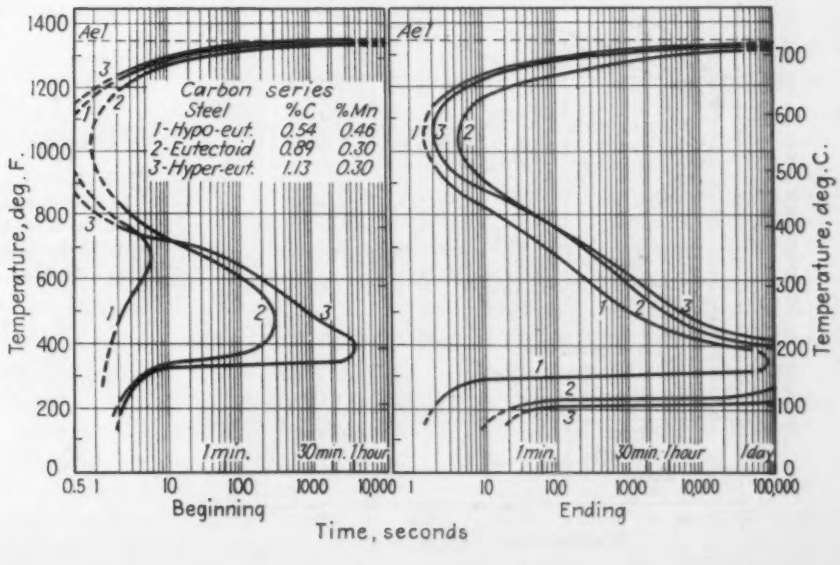
FIG. 4—Typical isothermal transformation curve showing influence of carbon. (Davenport)



work done by Bain, Davenport and others, a new procedure has been developed that helps greatly to disentangle the influence of these two factors. As stated by Edmund S. Davenport in the Fourteenth Campbell Memorial Lecture[6], delivered before the ASM annual meeting in October, 1939, "The principle of the method is shown schematically in Fig. 2. Individual specimens of suitably small dimensions are first rendered austenitic, then rapidly transferred to a liquid bath maintained at the particular temperature level (T_1) under investigation, held at that constant temperature for a predetermined period of time (P_1, P_2, P_3, etc.), withdrawn and immediately quenched in cold water or brine. The specimens are subsequently sectioned, polished, etched and examined microscopically. The essence of the method resides in the fact that any untransformed austenite remaining in a given specimen at the end of its sojourn in the constant temperature bath appears as martensite after this final quench."

Isothermal Transformation

In examining Fig. 2 for information that the heat treater can put to practical use, it is noted that during the period of time P_1, the unstable austenite did not transform while in the constant temperature bath, so when again quenched (but this time in water or brine), it all appears as martensite. As the period during which the successive test pieces are held in the constant temperature quench bath is progressively lengthened, the unstable austenite is transformed increasingly to ferrite and carbide structures until finally no martensite appears in the piece when quenched at the end of the test. In other words, a piece of steel is cooled rapidly to a temperature below its critical temperatures by quenching in a bath maintained constantly at a predetermined temperature. If held in this bath a sufficient length of time, a complete transformation to a structure identified with this temperature of transformation will occur. Such a procedure is called isothermal transformation.

In the Howe Memorial Lecture, delivered by E. C. Bain before the AIME in 1932, there was presented the diagram reproduced in Fig. 3 to illustrate the relation between cooling rate and the temperature of initial transformation of austenite. The line marked "beginning of transformation" should be noted. If the steel, cooled to about 1000 deg. F. at the rate shown as "slow cool B" or in about 1.5 sec., had been quenched immediately in cold brine at that point, all the untransformed austenite would be found present as martensite. It would be a condition like that shown schematically in Fig. 2 at the end of period P_1.

But suppose instead the steel is held in a constant temperature bath at 1000 deg. F. long enough to transform all the austenite and then is quenched immediately. A tough, ductile structure of the nodular pearlite type would result, wholly without formation of any martensite. If samples of any carbon or alloy carbon steel were subjected to a series of isothermal transformation treatments at numerous constant temperature levels under similar conditions, it would be found that at the various temperature levels the time before the transformation of austenite began varied from a fraction of a second to 30 min. or more.

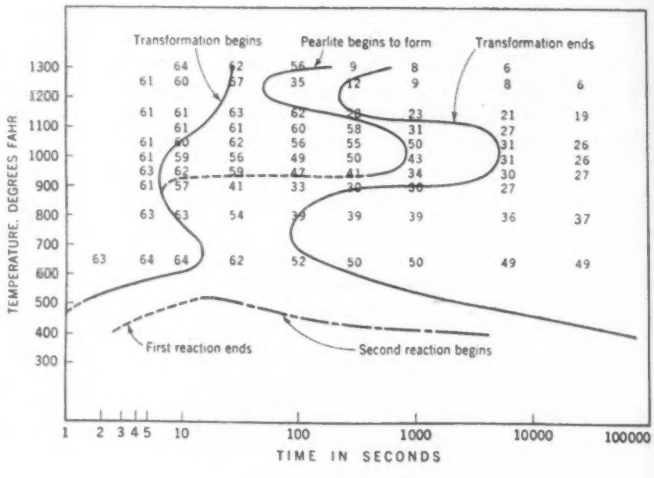


FIG. 6—Time-temperature reaction curve for chromium-molybdenum 4140 steel, from the Climax - Molybdenum Co.

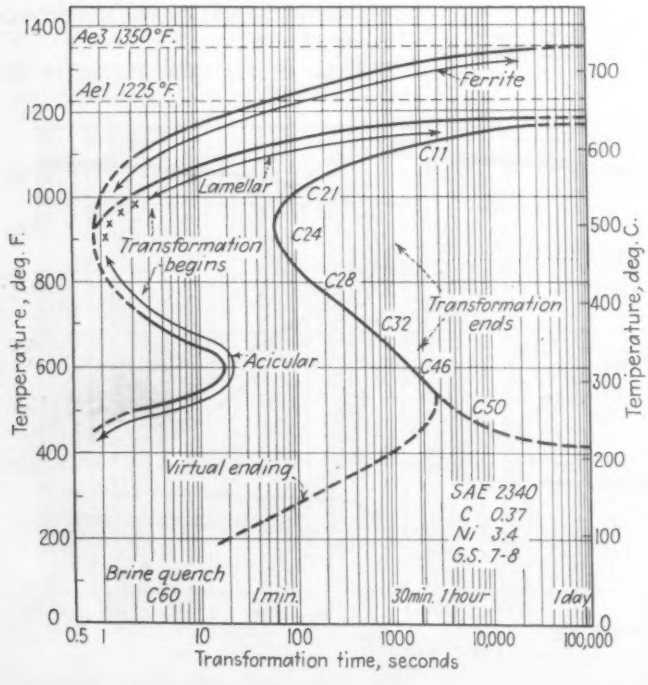

LEFT

FIG. 5—TTT curve of carbon steel alloyed with nickel, SAE 2340. (Davenport)

Likewise, the lapse of time from beginning to completion of transformation varied from less than 5 sec. to several days.

In Fig. 4, a typical isothermal transformation curve for carbon steels is reproduced from the paper entitled "Isothermal Transformation of Steels" by E. S. Davenport (Trans. ASM, December, 1939, p. 852). It is divided into two sets of curves, one group (on the left) recording the time to reach the beginning and the other (on the right) the time to reach the end of the austenite transformation.

Cooling Rate Affects Hardness

In examining these curves, it is noted that the curve marked 2 in Fig. 4 cuts the 1000 deg. F, temperature line (left side of the figure) at a point showing about 0.9 sec. of time. What does this mean? Simply that this 0.89 carbon steel must be cooled

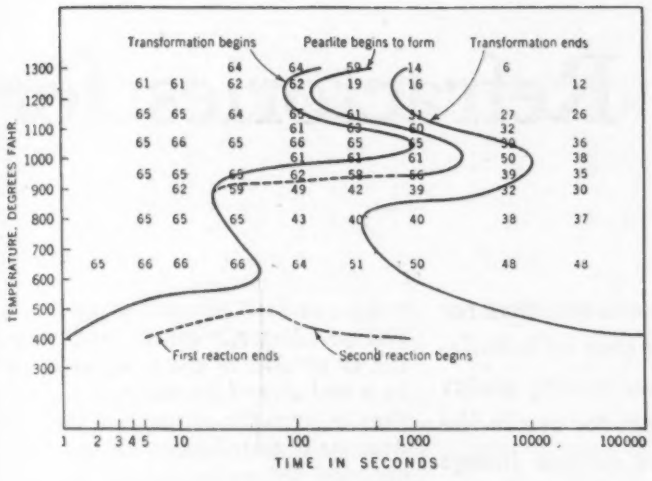

FIG. 7—Time-temperature reaction curve from chromium - molybdenum 4150 steel, from the Climax-Molybdenum Co.

(quenched) at such a rate that its temperature will be lowered from 1340 deg. F. to below 1000 deg. F. in not more than 0.9 sec. and to below 200 deg. F. in not more than 2 sec. if the structure of greatest hardness is to be obtained. The curve on the left, marked 2, where it intersects the 200 deg. F. line, indicates the beginning of transformation of the austenite. Where this line intersects the curve on the right side, marked 2, indicates the end of this transformation. Thus if the quench bath was maintained at 200 deg. F. and the steel kept in it for 20 sec., practically all the austenite would be transformed to martensite.

If the steel is quenched in a bath at higher temperatures, 1000 deg. F., for example, the time to complete transformation will be shorter but the product softer. Following the 1000 deg. F. line to its intersection with the curve marked 2 on the left, it is found that the quench bath must possess a cooling rate which will lower the temperature of the steel to that of the bath in not more than 0.9 sec. when transformation of the austenite begins. Now, following the 1000 deg. F. line to its point of intersection with the curve on the right side, marked 2, it is seen that if the steel is held in this bath for 5 sec., transformation will be completed.

Since, at the end of 5 sec. all austenite will have transformed to a structure identified with this temperature, the steel may be cooled at any rate, even by quenching in water and will be found to retain a fine pearlite structure. No martensite will be formed.

Curves 1 and 3 for steels with 0.54 carbon and 1.13 carbon respectively indicate that they would have to be cooled below 1000 deg. F. in much less than ½ sec. if full hardness is to be obtained. A very drastic quench such as brine would have to be used to obtain maximum hardness and highest physical properties. In all cases it is assumed that the pieces of steel are of such thickness that they can be cooled throughout in the time indicated.

The isothermal transformation curves of a few types of alloy carbon steels have been selected from the large number of curves prepared for various steels that have been published in trade magazines and technical papers. (See bibliography.) They illustrate the effect produced by nickel and nickel-chromium-molybdenum alloy elements. In Fig. 5, is shown a curve for SAE 2340 steel (by Davenport). In Figs. 6 and 7 curves are shown for SAE 4140 and SAE 4150 steel (from "Molybdenum in Steel," published by Climax Molybdenum Co.) respectively. They should be compared with the curves in Fig. 4. In them the curves for beginning and end of the transformation are drawn on the same diagram for ease in reading and interpretation.

The critical cooling rate is retarded progressively as alloy content increases, until, in the SAE 4150 steel, the piece can be fully hardened if cooled at a rate that will lower its temperature below 875 deg. F. (that is pass to the left of, not through the "nose" of the "S" curve) in about 20 sec., in contrast to the 0.89 carbon steel which had to be cooled in less than 0.9 sec.

The beginning of transformation for these steels in a constant temperature bath at 1000 deg. F. is retarded a progressively increasing lapse of time; 500 sec. for SAE 4150 compared to 1 sec. for SAE 2340. The end of transformation at 1000 deg. F. requires almost 10,000 sec. for SAE 4150 and 60 sec. for SAE 2340. The numerals close to the "end of transformation" curves show the Rockwell C hardness of the isothermal transformation structure.

The above theoretical information is presented merely to indicate how the data now made available in such curves may be used by the heat treater to assist him to obtain certain results under practical commercial conditions.

Ed. Note: Next week, the author continues with a discussion of cooling rates of various quenching media and design and construction of the bath as well as several commercial applications of the TTT curve.

Three Metals Plated Simultaneously

CERTAIN copper or brass parts of aircraft instruments that carry high-frequency currents must have high surface conductivity because of high-frequency current skin effect. Nickel, normally used to provide anti-corrosion protection, has high electrical resistance. Gold plate, which is a good conductor, is too costly.

Electrochemists at Westinghouse finally evolved an answer that disposed of this particular worry and provided a plating technique valuable in many applications unrelated to the original need. Special plating anodes are made of an alloy of copper, tin and zinc. With these soluble anodes, copper and brass parts are plated using standard plating practices.

The results are more than satisfactory, according to Westinghouse engineers. The plated surface has the necessary electrical conductivity for high-frequency applications and is far superior to nickel in corrosion resistance. Further, the finish is mirror-like, being surpassed in this respect only by silver itself. As to abrasion, the surface is roughly twice as good as the usual nickel coating. The new plating is entirely non-magnetic (not true for nickel) and is easily soldered, a fact of great value in many electrical applications. Furthermore, the new plating process has great "throwing power." In other words, deep interior surfaces (in objects with cavities) are plated much more uniformly than is possible with nickel.

. . . Carbon Refractories for B

. . . The use of carbon refractories in the blast furnace has thus far been limited to European practice. Although initial cost of installation is high, their long life and the elimination of inner cooling plates among other benefits make carbon linings economical for use in the United States. Herein, the advantages of various carbon linings over the conventional firebrick are discussed in detail.

REFRACTORY practice in Continental Europe is similar to that in the United States. Raw materials of practically identical composition are used for the manufacture of firebrick, silica, basic refractories, and super-refractory materials. The preparation of bodies, molding, drying and firing differ only insofar as differences in labor and market conditions justify the application of methods in one country that would be uneconomical under the changed conditions in another. Chemical, physical and technological test methods differ to some extent in details, but have fundamentally the same aims. Construction of kilns and furnaces is similar and so are specifications for refractory materials used in their linings.

Thus, for instance, magnesitic or dolomitic ramming mixes are used in the hearths of basic open-hearth furnaces; magnesite, chrome-magnesite or dolomite refractories in the structure above the slag line, and silica brick in the roof. In Europe and in the United States, considerable effort has been made to replace silica brick in the roof by basic refractories, but no definite solution has as yet been found to this problem. On both continents electrocast refractories are the recognized lining for large glass melting tank furnaces. Silicon carbide refractories are used almost exclusively both in this country and abroad in enamelling muffle furnaces; lightweight refractories have become the most important material of construction for most heat-treating furnaces of the metal industry. Chemically bonded basic refractories have begun to replace in Europe and in America the high-alumina lining of rotary kilns for burning cement. High-grade firebrick with an alumina content of more than 40 per cent and fired to cone 16 or higher are not traded as super-duty brick in Europe, but they are used in boiler settings, coal fired furnaces, malleable iron furnaces and many other structures to the same extent as in the United States.

In view of this similarity of trends, the fact that there exists a single but highly important difference between European and American refractory practice is rather surprising. In Germany, France, Belgium, Italy, Sweden and Russia, and probably also in some of the small countries, which are not important producers of iron, carbon refractories have been used in blast furnace linings for many decades. Approximately 80 per cent of Germany's pig iron and probably at least 60 per cent of the iron produced on the European continent is smelted in carbon linings and the trend to replace fireclay blocks in the hearth and the bosh of the furnace by carbon refractories seems to be increasing. Not a single furnace of the Western Hemisphere, on the contrary, is lined with carbon.

The reasons for this difference in practice are not readily apparent. A blast furnace is built for a campaign which lasts years and its lining has to deliver 1,500,000 or more tons of pig iron. Obviously, a blast furnace operator will eschew the idea of using an unfamiliar refractory material in the lining. But technical progress always has involved risks of this very nature and America's industry has proved often enough that it can take them. Nor can the fact that the carbon lining is more expensive than the fireclay explain why carbon refractories have never been used in the United States. The relation between the prices of firebrick of blast furnace quality and machined carbon blocks is approximately 1:2.5 per unit of weight, or 1:1.7 per unit of volume in Europe. Nevertheless, the carbon lining is considered the more economic by a majority of European producers. Finally, even the assumption that the American metallurgist is not acquainted with carbon refractories does not hold true. Rammed monolithic carbon linings as well as molded and fired carbon blocks are consumed in large quantities in the manufacture of aluminum, and large carbon blocks form the linings in ferrosilicon and ferromanganese furnaces. Considerable quantities of carbon refractories are, moreover, consumed by other industries, as for instance, in the manufacture of phosphorus, phosphoric acid and calcium carbide. These carbon refractories are manufactured in this country and their chemical, physical and technological properties are to all practical purposes identical with those of the European blast furnace block.

Properties of Carbon Refractories

One of the fundamental properties of refractories, that is, of materials of construction which serve to confine heat and high temperature to given spaces, is their melting point. Pure carbon does not melt under atmospheric pressure; it volatilizes at approximately 6638 deg. F. No exact data are available on the effect of impurities on the behavior of carbon at this extremely high temperature. Carbon refractories contain approximately 6 to 8 per cent of non-combustible matter, which undoubtedly has some influence on the volatilization temperature. Still, these carbon blocks or rammed linings do not even soften at temperatures which would cause the melting not only of super-duty brick, but even of pure thorium oxide, the most refractory of all industrially used super-refractory materials.

A high melting point is only one of the important characteristics of refractory materials. Even more critical than the melting point or pyrometric cone equivalent is the highest temperature at which a refractory construction material still retains satisfactory structural strength. Ordinary firebrick softens under a load of 50 lb. per sq. in. at temperatures of 2370 to

Blast Furnaces . . .

By DR. JOSEF M. ROBITSCHEK
Director of Research, U. S. Stoneware Co., Akron, Ohio

2550 deg. F. Super-duty firebrick will support a load of 50 lb. per sq. in. at temperatures of 2800 deg. F. or more. This improvement of the load bearing capacity of firebrick, achieved within the last 20 years, is undoubtedly one of the factors responsible for the increase of the life of blast furnace linings from an average output of 750,000 to 1,500,000 tons of pig iron. High-alumina refractories, silica brick and modern basic refractories begin to soften under a load of 50 lb. per sq. in. at 2900 to 3250 deg. F. Even at 3700 deg. F., carbon refractories have still approximately the same mechanical strength and load bearing capacity as at ordinary temperatures.

Next in importance to refractoriness and structural strength at high temperatures is physical stability over the temperature range in which the refractory is used. The fact that any one constituent is subject to crystalline changes accompanied by volume changes does not exclude a structural material from its application as a refractory. However, certain safety precautions must be taken. Refractory life may be shortened and its application limited by the construction or the operation of the furnace. In this respect again, carbon refractories are not inferior to any other refractory material. No physical changes that might cause a sudden expansion or contraction and thus necessitate special caution in heating or cooling take place in carbon refractories under industrial conditions.

Not only sudden volume changes, caused by transformation of crystalline constituents, but also the reversible thermal expansion of refractory materials may be responsible for a sudden destruction or a slow deterioration of furnace linings by dilatation stresses. In linings which are heated from one face only, internal stresses, which tend to cause a mechanical spalling of the refractory, are directly proportional to the coefficient of thermal expansion and inversely proportional to the coefficient of heat conductivity of the refractory. Again, carbon refractories are superior in this respect not only to that type of firebrick which they replace in the blast furnace lining but also to most other refractory materials. Over the range of 100 to 2900 deg. F. the coefficient of thermal expansion of carbon blocks is 1.9×10^{-6} compared with approximately 5.0×10^{-6} for firebrick. In addition, the thermal expansion curve of carbon refractories approaches a straight line over this interval. Finally, the coefficient of heat conductivity of carbon blocks is approximately 10 to 15 times that of firebrick. Aside from its favorable effect on the resistance to thermal stresses, the extremely high heat conductivity of carbon blocks is obviously of special importance in a structure that is cooled from the outside.

In their industrial application, refractories are exposed not only to mechanical and thermal stress, but also to chemical attack by solid, liquid and gaseous substances. At the high temperatures reached in the hearth and bosh of the furnace, firebrick will readily react with alkalies, lime, magnesia, iron oxides and other constituents of the blast furnace slag. Without very intensive cooling, this chemical action would probably destroy the firebrick lining within a few days. In spite of water jacket and cooling plates, the reaction results in an erosion of bosh and hearth and is responsible for the loss of iron through the furnace hearth and for the formation

TAPPING a blast furnace at the plant of Colorado Fuel & Iron Co.

and growth of the salamander. At very high temperatures, reactive carbon will reduce most of the oxides present in blast-furnace slag to metals or react with them to form carbides. Carbon refractories will, however, not react chemically with any constituent of the slag under any temperature and pressure to which they may be exposed in the blast furnace. Molten pure iron or low-carbon steel will dissolve carbon and therefore pick up carbon from a carbon lining, until it reaches saturation. In the blast furnace crucible, however, the iron is saturated with carbon from the coke and will not attack or dissolve the refractory lining.

Thus, carbon is a refractory material which at industrial temperatures does not melt, soften or collapse under load, does not suffer sudden volume changes and does not react with oxides present in fuel ashes and in metallurgical slags. Were it not for the fact that carbon may not be exposed to oxidizing atmosphere at temperatures above 650 deg. F., carbon refractories would form the really ideal lining for all kilns and furnaces whose linings deteriorate rapidly under the action of high temperature, mechanical stresses and chemical attack. The combustibility of carbon linings which excludes their wide application is, however, of no importance in the oxygen-free atmosphere of the blast furnace.

The Carbon Lining

Two different types of carbon linings—monolithic and block—are used at present for hearth and bosh of blast furnaces up to the mantle.

The rammed lining seems to have been first used in Germany's industrial district of the Ruhr and the Lower Rhine. Some of the largest furnaces built in this district during the last decade before the war have monolithic bottoms and boshes. German blast furnace operators brought this practice to Russia, where quite a few furnaces of this type were built. To the writer's knowledge, monolithic carbon linings were rather the exception in other European countries. Information about the current number of furnaces operated with rammed linings is not available. Reports from single plants seem to indicate a tendency to abandon the monolithic structure in favor of the large fired and machined carbon block. Still some operators consider the rammed lining, which is by far less expensive than the carbon block lining, as the most economical installation.

Coke and tar are the raw materials from which prefired carbon refractories as well as ramming mixes are made. High-grade foundry coke of low ash content is used because its dense structure makes for higher mechanical strength and lower combustibility than gas or blast-furnace coke. It is crushed and ground to a grain size which corresponds approximately to that of the U. S. Standard Sieve No. 18. Crushers and grinding devices of various construction are used for this operation. Coke grain must not contain excessive quantities of fine dust. The coke has to be dried thoroughly before or after grinding to prevent formation of water vapor in the paste during preparation or molding. Coal tar with a high content of non-volatile carbon, which yields a coked residue of high density and good mechanical strength, forms the binder for the ground coke. Like the coke, it has to be free of water. To increase density and strength of the refractory, pitch, petroleum asphalt and other bituminous substances of high melting point are dissolved in the hot tar before it is mixed with the coke.

Pastes from which monolithic linings are made contain usually five to six parts of coke to one part of the tar-pitch mixture. The raw materials are heated to about 250 to 300 deg. F. and mixed either with spades or worked in steam-jacketed kneading mills. The temperature of the paste has to be kept within fairly close limits during mixing and during its use. Unhomogeneous lining of low strength will result from mixing too cold materials, while a brittle, non-workable paste and a brittle lining of unsatisfactory abrasion resistance will be obtained if local overheating causes loss of volatile substances or partial combustion. Immediately after mixing, the hot paste is rammed into place in layers 1½ to 2 in. thick. Wedge-shaped iron rammers which are kept hot during the operation are used. Starting from the firebrick base of the furnace, a solid jointless hearth 5 to 7 ft. high is thus built up. Fireclay blocks are then laid to form the taphole since carbon would be destroyed at that point by oxidation. Then the crucible is built up in the same way as the hearth, the monolithic lining being brought around the tuyeres up to the mantle. Since carbon-lined furnaces operate without cooling-plates in the bosh, no provisions for these plates need be made. Hearth and bosh linings are exposed to oxidation after the furnace has been blown in and as long as the crucible has not been filled with iron. To protect the carbon refractory during this initial period, its interior surface is covered with one course of firebrick.

The installation of this monolithic lining is slow and unpleasant. The men have to be provided with respirators or gasmasks to protect them against the pungent and noxious fumes which arise from the hot paste. Heated tools and hot paste make this measure especially inconvenient and only skilled and reliable men are capable of ramming a good lining under such conditions. If, however, this work has been done expertly, a lining which is free from laminations, cracks and joints will result. Such a lining can outlast considerably the best firebrick lining and is much less expensive than a carbon lining built of prefired and machined carbon blocks.

Carbon Block Lining

The second type of carbon lining which is used at present in most of Europe's blast furnaces is a prefired lining built of large machined blocks. These refractories are produced by manufacturers of carbon electrodes and by large producers of fireclay refractories, who have taken up this production as a protection against the loss of an important volume of output. The original carbon block, which was approximately the same size as the standard blast furnace fireclay block, has almost disappeared. Since carbon bodies have no drying shrinkage and their firing shrinkage is considerably lower than that of fireclay bodies, they lend themselves admirably to the manufacture of especially large shapes. This fact constitutes an important advantage in their application as blast furnace hearth blocks. Key-shaped hearth blocks in lengths of 7 ft. or more, weighing about 3000 lb. each, and smaller blocks of 800 to 1000 lb. each for the lining of the crucible are generally used at present.

The paste used in the manufacture of these prefired blocks is again coke and tar. Both materials are mixed in heated apparatus and the mix is molded immediately. Small blocks of standard shapes are either pressed or extruded. Large blocks are rammed into molds with heated tools. The green ware attains sufficient strength to be handled on cooling. Small blocks may be set into the kilns 24 to 48 hr. after having been molded, while a cooling time of 4 to 6 days is sufficient even for the largest pieces. Most blocks are fired in periodic downdraft kilns. Obviously, oxidation of the refractory has to be avoided during firing. Muffle walls of fireclay slabs are, therefore, built around the blocks and all interstices between single

blocks and between blocks and walls are filled with crushed coke. Then the blocks are covered with an 8 to 10 in. thick coke layer which is covered with with a tight layer of firebrick. Because of the difficulties encountered in setting large and heavy blocks through kiln doors, special muffle kilns with removable roofs have been constructed by several manufacturers. Firing schedules depend in some degree upon the size of the blocks. Temperatures of 1922 to 2012 deg. F. have to be reached inside the muffle and the blocks have to be soaked at these temperatures for several hours to bring about complete carbonization of their bond. On the average, the kiln is preheated slowly for about 48 hr., during which time most of the volatile constituents of the tar are driven off. The maturing temperature may then be reached within another 48 to 72 hr. and held for 6 to 12 hr. After this heat treatment, the refractory has no appreciable shrinkage even if exposed to temperatures of more than 3000 deg. F. The fired blocks are cut to size, machined and numbered, so that they may be laid with tight and impervious joints. The use of mortar or paste to fill the joints is eliminated. Some technological properties of a German carbon block, made by this method, are listed in Table I.

For all practical purposes, a lining built from these prefired machined blocks may be considered jointless. Its advantages over the rammed monolithic lining are a higher mechanical strength and a higher heat conductivity. In its outer parts the monolithic lining never attains those temperatures necessary to carbonize its bond. After a partial volatilization of the hydrocarbons, therefore, it remains porous and soft where it was not directly exposed to heat. More important, however, than higher mechanical strength and better heat conductivity is the speed with which a hearth consisting of three layers of large, machined and numbered blocks can be built when compared with the slow and tedious task of ramming single thin layers of hot carbon paste, which form a monolithic carbon lining.

Carbon vs. Firebrick Lining

American authors have several times expressed the opinion that the successful application of carbon linings in European furnaces is due to the fact that continental Europe has no flint clay deposits and that the European blast furnace fireclay block is, consequently, of lower quality. A comparison of chemical composition and technological test data for an American fireclay block A* and a Czechoslovak blast furnace block C in Table II does not confirm this opinion.

Because of the lack of flint clays, the European manufacturer of blast furnace blocks has to use bodies which consist of 93 to 94 per cent of hard fired grog together with only 6 to 7 per cent of bond clay. To produce from such bodies refractories of sufficiently dense structure, the grog has to be carefully graded; bond clays of high alumina content selected; the body rammed with pneumatic tools into collapsible iron molds, and the blocks fired to temperatures above cone 16. The result of these rather expensive operations is a brick which contains less fluxes and has a higher pyrometric cone equivalent than the average American block.* The refractoriness-under-load of the European brick is, moreover, very satisfactory. A direct comparison of this property of the American and the European block is not possible because of the difference in test procedure. Result of the European test method is not the deformation which the brick suffers at a specified temperature, but that temperature at which a sample that has been cut out of the block shows the first signs of softening under load, and that temperature at which it begins to collapse rapidly. Still, neither these figures nor the values for chemical

H. M. Kramer, "Refractories Service Conditions in the Blast Furnace." Journ. Amer. Ceram. Soc. 25 (1942), p. 312.

**It is, however, to be noted, that European standards for the determination of the pyrometric cone equivalent of firebrick call for samples that have been cut out of the brick, while the test cone is molded from a finely ground sample according to ASTM Standard Test Method C24-42. In single instances the European method will yield slightly higher results than the ASTM test.*

Heat conductivity, B.t.u. per sq. ft. per in. per deg. F. per hr.	40

composition, porosity and P.C.E. justify the assumption that the European blast furnace operator has to use carbon refractories because of an inferior quality of those fireclay blocks which are at his disposal.

It is difficult to judge the performance of blast furnace refractories on the basis of the total output of the furnace. The iron content of the ore, the design of the furnace, the number and length of shutdowns during one campaign, grading and sintering of the ore, the quality of the coke, wind pressure, stock distribution and other factors will affect the total output of the furnace. The necessity of major repairs on the mechanical equipment or the destruction of inwall refractories above the mantle by the action of alkalies, by carbon deposition and by abrasion may cause the end of a campaign at a time when bosh and hearth might have still produced 100,000 tons or more of pig iron. Still, a production of 2,000,000 tons from one lining of an 800 to 1000-ton furnace can be attained or surpassed only if hearth and bosh of the furnace have been lined with the best quality blocks available. This 2,000,000 ton mark has been reached during the past few years not only in quite a few American furnaces but also in several European furnaces that were lined with good fireclay refractories. Considering that the average iron content of European ores is lower than that of the American ore and that consequently the quantity of slag, which is the most important destructive factor in the bosh, is higher per ton of iron in Europe, the statement that there might exist any appreciable difference in the quality of fireclay refractories which might justify their exclusive use in the United States and exclude them from application in the large furnaces in Europe cannot be upheld.

It is equally difficult to compare the performance of carbon-lined and fireclay-lined furnaces without regard to factors other than furnace output. To the writer's knowledge, at least two 1000-ton furnaces with monolithic carbon lining were under fire in Germany in 1939 after having each produced 3,000,000 tons of pig iron. At the same time several furnaces, some of them with rammed linings, others with carbon block linings, were in operation at the Lower Rhine in Belgium and in Russia with production records well over the 2,000,000 mark and with life expectancies near or over 3,000,000 tons. On the other hand, German, Russian and French carbon lined furnaces had to be torn down without having reached the 2,000,000 ton goal; the end of the campaigns being brought about, however, by causes outside of the hearth and bosh lining.

Even though carbon-lined furnaces are known to have produced in one campaign more iron than any firebrick lined furnace, no proof is available for the statement that the carbon lining considerably lengthens the life of a blast furnace. With our rather incomplete knowledge of the mechanism of wear of blast furnace linings, such proof cannot be furnished even from very complete data on campaigns of carbon-lined furnaces. Expectations of longer campaigns could not, therefore, be sufficient to induce a majority of European iron producers to abandon the fireblock lining in favor of the more expensive carbon. The carbon lining offers, however, a series of other very important advantages and the sum of these advantages seems definitely to outweigh the increase of initial installment cost.

Probably ranking first among these advantages is the safety and reliability of a lining which has none or at least considerably fewer joints than the fireblock lining; which is not corroded by slag or metal and which, due to its high heat conductivity, may be cooled very intensively. With the increases of hearth diameters, losses of iron through the hearth have become more frequent and more severe. The carbon lining eliminates these losses almost entirely. Shutdowns, loss of metal, loss of time and accidents are avoided and this safety, which cannot be expressed in tons of molten iron, may in itself compensate in single instances for the higher cost of the lining.

Perhaps no less important from purely economical reasons is the fact that, because of the high heat conductivity, the exceptionally high strength at elevated temperatures and the chemical inertness of the refactory, the carbon lined parts of the furnace need to be cooled on the outside of the shell only. No cooling plates are used inside of the carbon lining and in comparing the prices of fireblock and carbon linings, the costs of installation and maintenance of the copper cooling plates have to be considered for the firebrick lining only.

Chemical destruction of the fireblock hearth causes the formation of a salamander, which especially in the present large diameter hearths attains considerable dimensions and usually eats deeply into the concrete founda-

Beginning of deformation, deg. F.		2,786
Sudden softening, deg. F.		2,948

tion of the furnace. The expenses and the loss of time resulting from the tearing down of the lining, the removal of the salamander and subsequent relining increase considerably the initial cost of the firebrick lining. Although carbon refractories do not react with slag and metals, mechanical erosion and abrasion of the carbon lining take place and the iron does become embedded in the carbon hearth. A salamander in the carbon lined furnace, however, does not even reach the firebrick base on which the carbon lining was laid and losses of iron through the hearth into the foundations are, therefore, entirely avoided.

The initial difference between the costs of the fireclay and the carbon lining is further decreased not only by savings in time and labor when the furnace has to be rebuilt and by the easier removal of the large carbon blocks than the corroded and slag and metal saturated fireclay blocks, but also by the salvage of entirely unchanged or only slightly damaged carbon refractories.

These economic advantages together with a simpler, smoother and safer operation are the reasons why most blast furnace men, once having operated a carbon lined furnace, decide in favor of the expensive carbon lining. Undoubtedly, a carbon lining has a much longer life than the fireblock lining. The life of the carbon lined furnace is not limited, therefore, by the life of its hearth and bosh, and exceptionally long campaigns with extraordinarily high total production have been and will be obtained, if shutdowns for reasons other than destruction of hearth and bosh can be avoided.

In peacetime the iron industry of the United States consumes more than one million dollars worth of blast furnace refractories annually. In one campaign single blast furnaces produce 2,000,000 tons or more of pig iron. The average life of a blast furnace lining is, however, far below this figure and the life of hearth and bosh is one of the factors determining this limit. The use of carbon as a blast furnace refractory offers one means to increase this average. Therefore, the carbon lining which has proved the most economical in large European blast furnaces, but has never been tried in this country, deserves earnest consideration by the American iron industry.

Electronic Device Detects Oxygen in Furnace Gases

ONE way of detecting the presence of unwanted oxygen and water vapor in heat-treating atmospheres is by passing the gas over a cool surface and by noting the temperature at which condensation occurs. This temperature of condensation (dew point of the gas) varies between =40 and =70 deg. C. depending upon the requirements of the process. Even skilled operators differ in their estimates of dew-point temperature, especially when it is of the order of =40 deg. or lower. Furthermore, the process is not continuous and requires the operator to take periodic samples of gas to make the test.

An experimental device developed by Westinghouse utilizes electrons to do the detecting. Oxygen and water vapor are ionized by electron bombardment, whereas constituents of furnace gases are not. The arrangement draws a sample of the gas mixture past an electron gun. As long as the gas is free of impurities, the electron current is constant. However, when oxygen or water vapor are mixed with the gas, some of the electrons are utilized in forming negative ions. This causes a measurable decrease in electron current. Although most electron tubes are vacuum devices, the tube employed here is essentially a diode tube which operates with both ends open. The electron emitter and the plate continually operate in a stream of hot furnace gases and provide a continuous indication of gas quality. At present the new development is strictly a laboratory instrument and is not commercially available. Applications of the dew-point indicator will probably be restricted to certain types of furnace gases.

Plastic Dipping for E

By HARRY FORSBERG
President, Japan Co., Cleveland

o o o

THE extraordinary rigors to which war supplies are subjected in transit and in landing have resulted in a series of very stringent packing specifications. There is no question that such safeguards are necessary, for equipment shipped abroad may be attacked by salt air, salt spray, unusual humidity and extremes of heat and cold; it may be tossed overboard for the tides to deliver to some remote shore and may lie under the burning tropic sun for days; it may be exposed to engine room heat on the way to an arctic region where its temperature will drop 100 degrees upon landing.

Such conditions have been combatted by dipping metal parts in various types of grease and wax, by wrapping them in waterproofed papers, and by packing them in waterproof containers. There are several distinct methods of doing this, but they all have one thing in common—they slow down the flow of supplies to the fighting front.

A new method of preparing metal parts has been developed for export shipping which is fast and efficient. This method, which is described by the Ordnance Department as "compound protective ethylcellulose stripping," has not yet been given blanket approval by any of the armed services, but it has passed muster and authorities in a number of specific cases, notably in the preparation of spark plugs for shipment overseas. For the time being, those wishing to adopt it should make a separate application to the government for each job under consideration.

Compound protective ethylcellulose stripping consists of dipping the parts to be treated in a molten plastic material, from which they pick up a thin, completely enveloping film (See Fig. 1). This film cools in about 4 sec. to form a tough, waterproof, abrasion-resistant corrosion-resistant coating which will withstand temperatures over 300 deg. F. without melting and sub-zero temperatures without becoming brittle. No wrapping and rewrapping, and no use of paper or similar materials are involved. Once coated, the parts can be boxed for shipping without delay.

Although the film applied fits the treated parts like a skin, it has no adhesion and can be stripped off in a few seconds simply by slitting it from top to bottom with a pocket knife (See Fig. 2), leaving the protected parts clean and ready for use. Thus it is a time saver at both ends of the war supply line.

Compound protective ethylcellulose stripping is suitable for protection of a variety of different parts. It is particularly suited for such things as machined surfaces of axle shafts,

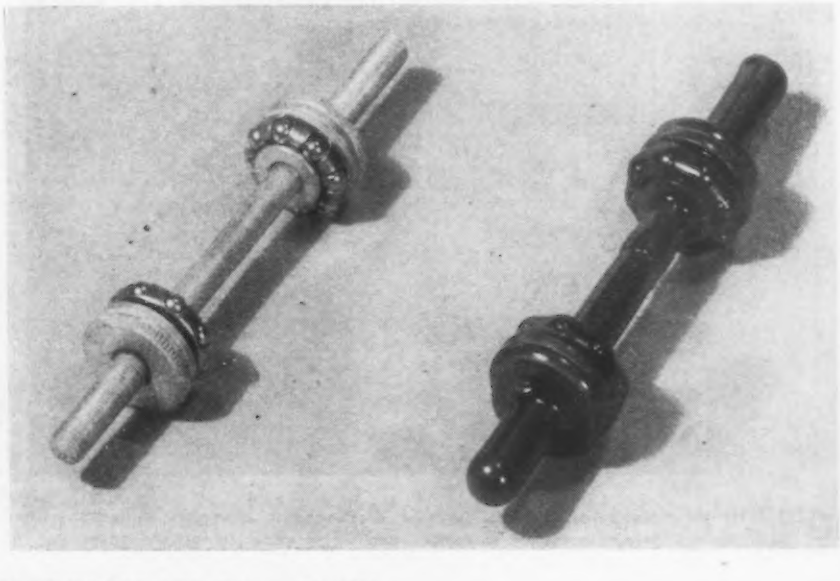
RIGHT

FIG. 2—The plastic film being stripped off. The film comes off without sticking, even though it encased the part so closely that every thread of the shaft left a perfect impression in the film.

o o o

BELOW

FIG. 1—A small axle shaft with a bearing on either end, before and after being coated with ethylcellulose stripping material.



Export Shipment

complete axle assemblies, camshafts, connecting rods, gears, intake and exhaust valves, and the like. In treating parts with large holes, care should be taken to plug the holes before dipping, although there is no reason why interior surfaces cannot be coated, so long as there is adequate room to strip the film off. Small blind holes are bridged satisfactorily by the film, although it is not possible to say exactly how small a hole will be bridged or how large a hole will not. Experimental dipping has been found necessary in many cases.

Coating of very thin parts is not recommended, because the metal may act as a knife to cut through the film. The film will withstand considerable pressures without appreciable flow or cutting through, although extremely heavy parts with small or narrow bearing surfaces should be cushioned with soft packing or supported with blocks to increase bearing surface.

No change in metal clearing standards is effected by the use of this plastic stripping materials. Fingerprints will cause rust under it just as they will under any other form of coating. Surfaces are prepared as outlined in "Instructions for Cleaning and Preserving Ordnance Material M-406 (TM-38-305)." In fact, with this method, there is the additional possibility that dirt on the parts will contaminate the melt, and therefore parts must be cleaned with care.

. . . All types of machine parts may be dipped in ethylcellulose plastic, which affords complete protection to the point of delivery. The coating is transparent and may be stripped off with complete ease.

The simplicity of this method indicates that it will remain in use for export shipping in time of peace, and at least one other important use has been suggested for it. At present, the film applied is somewhat cloudy and varies in color, but it probably will be possible to produce it in transparent form. It could then be used instead of grease, paper wrapping, cloth bags and other protective encasings for domestic shipping. A film-protected metal part such as an engine valve, with its identification number in plain view through the film, could be placed in a stock or supply room and when the need for it arose, could be stripped in a few seconds for immediate use without cleaning.

To return to the present, it is not supposed that compound protective ethylcellulose stripping will supplant in every case the standard methods now in use. These procedures are planned to meet U. S. Army specification 100-14A, U. S. Navy specification 39P16A, and U. S. Engineers specification E. M. 100.

Titanium Pre-Dip Process Increases Life of Zinc Coatings

MILLIONS of dollars have been spent on paints, finishes, and treatments to delay the inevitable rusting or oxidation of metals. Conspicuous success has been achieved by treating metal surfaces with phosphoric acid solutions to increase paint adhesion and thereby improve corrosion resistance.

Zinc remained stubborn and would not take the phosphate coating evenly. Early in this work a curious phenomenon was discovered by Westinghouse engineers. If the zinc surface is wiped with the hand, a brush or a cloth before it is treated, excellent phosphate coating results. Just why this happens is not altogether clear. Nevertheless, many methods of wiping the zinc surface before treatment were attempted. In production, however, uniform wiping is difficult even on plane surfaces; on irregular objects it is impossible.

In manufacturing zinc plated frames for outdoor-type watthour meters this problem of preparing the zinc surface to take the secondary protective coating of paint became serious. A young Westinghouse chemist proposed doing the wiping chemically instead of mechanically. Countless dips were tried with indifferent and inconsistent results. One day disodium phosphate was tried, with excellent results that could be duplicated as long as that particular batch of phosphate lasted. With the next lot of disodium phosphate the result was a failure, although ordinary chemical tests revealed no difference. Finally in desperation a more critical test was made and a faint trace of titanium—one part in a million—was found. Herein lay the answer. For some reason a mere whisper of titanium is the magic that makes the pre-dip solution of disodium phosphate work as a chemical wipe on zinc for subsequent and final phosphating treatment.

The process is now being applied extensively on a commercial scale for protection of hundreds of zinc-coated machine parts for both war and peace. Certain war products receive a layer of zinc only 0.0003 in. thick. When given the titanium pre-dip and the normal phosphate coating they are able to meet the 100-hr. salt spray test with ease. Without the titanium pre-dip, corrosion appears in an hour or two.

The titanium pre-dip has several signal advantages for phosphate anti-corrosion treatments that are otherwise conventional. It secures a protective coating on zinc and provides a finish that does not necessarily require further coating. In some cases, to meet the salt spray test, parts were made corrosion-resistant by electroplating first with copper and then applying a baked black enamel finish. Phosphating with titanium pre-dip is much faster, less expensive, requires no critically short copper and is many times more protective.

The pre-dip can also be used for phosphating of steel. While the resulting improvement in corrosion resistance is not always so marked as with zinc, it reduces the time required to form the protective coating.

Boron Treated Electrode Coatings Aid

Cast Iron Welding

. . . Boron introduced into the coating of Monel welding electrodes appears to behave as a flux, permitting thorough binding between the monel and cast iron, giving an excellent weld.

o o o

By DR. J. A. NEUMANN
Director of Research, American Agile Corp.

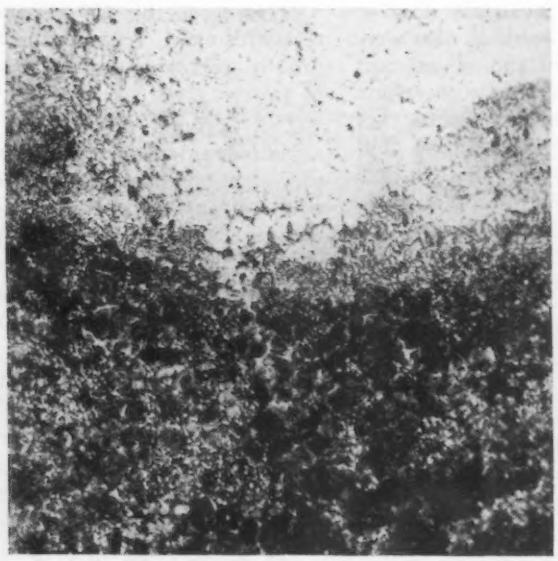
o o o

THE welder of cast iron realizes that the success of this work depends upon full knowledge of the behavior of the welded piece under the heat of the arc and after cooling. Familiarity with the stresses that occur and a knowledge of the electrodes applied are further requirements for successful cast iron welding. The metallurgist, on the other hand, is responsible for what the electrode will do, and, through research, for the final achievements.

For welding cast iron without preheating — and where machinability after welding is essential — non-ferrous nickel-copper (Monel) electrodes are used, since these alloys do not harden and do not absorb free carbon from the molten pool. The monel electrodes are heavily coated, but the coating composition until recently has never been regarded as very important. Nevertheless, the coating is important to a great extent in influencing fluidity, soundness, binding properties, and penetration. Furthermore, in combination with applied heat, the coating can practically eliminate the narrow martensitic hard zone found between the monel deposit and the fused cast iron.

This fusion line, when it results from welding with a mild steel electrode, causes the carbon to be absorbed and the ensuing hardness is in the range of self-hardening steels with carbon contents of 0.9 to 0.7 per cent, as shown in Figs. 1a and 1b. When welding with Monel electrodes with a fluxing coating, this range is still present, although to a lesser degree because of the lower melting point of the Monel metal and because of its immunity to carbon. To eliminate these hardened zones entirely, a study was made of what occurs during the heating and cooling, and the possible control of the chemical processes of the fusion line.

The chemical composition of cast iron is responsible for its mechanical properties, and the chief ingredients, apart from iron, are carbon, silicon and manganese. The carbon content is usually between 2.5 and 4 per cent. As



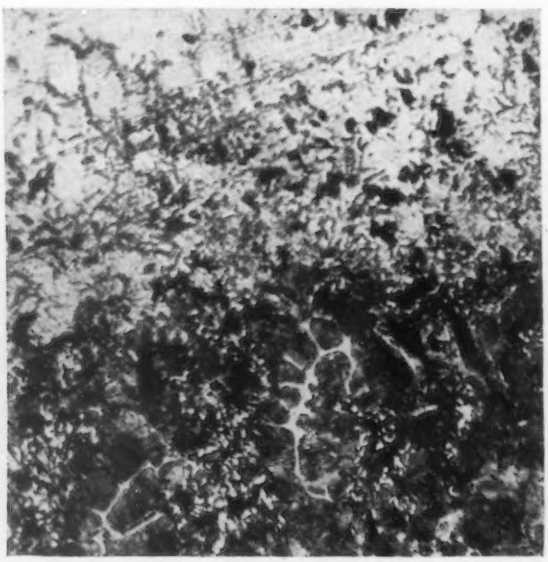


Fig. 1a (Left) — (100 diameters, nital etch)
Fig. 1b (Right)—(300 diameters, nital etch)

This microstructure of the weld fusion line shows dendritic structure and grain formation in nickel rich areas. The pearlitic zone contains spots of cementite close to graphite flakes.

the silicon content is chiefly responsible for keeping the carbon from turning into solid solution with the iron to form cementite, the silicon content is largely dependent upon the carbon content, but it is not lower than 0.75 per cent.

The hardness of gray cast iron will normally range from 130 to 200 Brinell and possesses good machinability. Small additions of nickel usually increase the hardness. Hence, it has been found that 1 per cent nickel at 3.5 per cent carbon and 2.6 per cent silicon results in a hardness of about 220 Brinell in the cast iron; while 2 per cent nickel with the same carbon and silicon content yields an iron running about 260 Brinell. By decreasing the silicon content, the hardness would also increase.

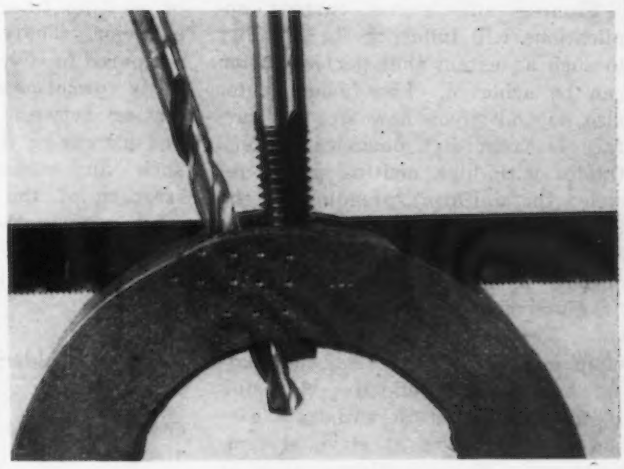
Alloy Effects

Summarizing the effect of the alloys in cast iron, it can be said that the graphite formation is promoted by the alloying elements silicon, nickel, copper, aluminum, titanium, zirconium, and boron; while the cementite formation is furthered by chromium, manganese, molybdenum, vanadium, sulphur, and oxygen.

Because Monel contains 67 per cent nickel and 29 per cent copper and does not contain cementite promoting alloys, it is obvious that this alloy has been chosen to make weld deposits on cast iron. From a chemical point of view this was promising, but cast iron heated to melting temperature and then chilled can be changed from the ferritic to a pearlitic matrix. And, since the solidification shrinkage is also associated with the formation of the grain size, segregation can be brought about where the carbon gets into solid solution to form small particles of hard cementite.

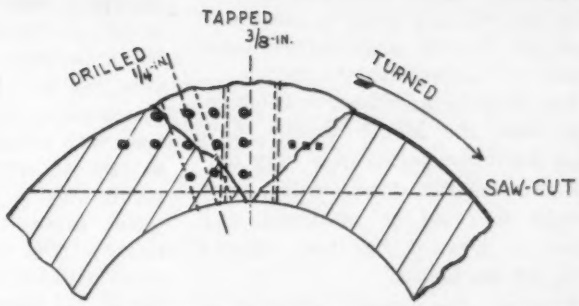
When the molten drops of Monel are deposited on the cast iron surface, which is cold and behaves as if it is not wetted, the surface tension of the liquid metal prevents thorough binding and the weld has not sufficient flowing power to wet and fuse with the surface. With increasing carbon, the cast iron has a higher surface tension than steel and one much higher than Monel.

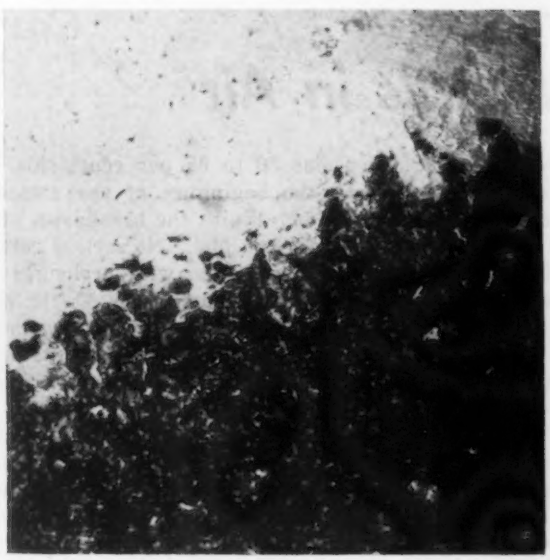
Fig. 3a—(Tested weld)



This 4-in. ring with an 0.75-in. wall thickness was welded with a Monel electrode designed to impart boron through its coating. No hard spots were found in the weld, and drilling, tapping, sawing, and turning were performed without difficulty.

Fig. 3b—(Position of tests in weld)





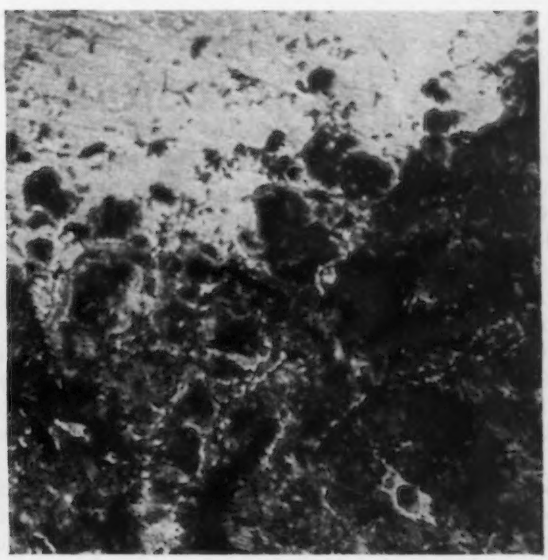


Fig. 2a (Left—(100 diameters, nital etch)
Fig. 2b (Right)—(300 diameters, nital etch)

A sharp distinction indicates the junction of the weld made with Monel electrodes, the coating of which was boron treated. Carbon diffusion is not visible and no change occurred in the cast iron.

Fluxing and higher current applications will influence the liquidity to such an extent that perfect fusion can be achieved. The fusion factor also depends upon how free the surface is from dirt particles or oils. Oxides with high melting points restrict the uniform spreading of the fluid metal and thereby decrease binding qualities. To avoid such conditions, a strong refiner, such as titanium or zirconium must be present. Ferro-titanium or ferro-zirconium is added to the electrode coating for the most effective cleansing of the metal and to withdraw carbon from solution at elevated temperatures. These additions melt at 2370 deg. F., and dissolve quickly in cast iron leaving a deoxidized metal ready for fusion with the monel.

Yet all these additions, in combination with the Monel deposit, have none the less resulted in a very narrow martensitic zone, which, even though it could be machined, still shows a marked hardness against filing or machining.

Through the small addition of boron in the form of ferroboron, a remarkable change takes place. The martensitic hard zone disappears as definitely shown by the micro-photographs, but the explanation for such an occurrence is not yet quite satisfactory. It appears as if boron behaves as a flux, permitting thorough binding between the Monel and the cast iron, washing aside the graphite flakes and wetting the surface. It may be possible that the temperature or wetting time also influences this behavior. The whole process may be compared to silver solders, which suddenly spread over larger areas, penetrating between the graphite flakes and increasing the binding surface to such an extent that the tensile strength of the connection becomes much greater than the welded area, thus obtaining 100 per cent safety for the weld. This is shown in Figs. 2a and 2b.

Welded Cast Iron

In practical application, Figs. 3a and 3b show a cast iron ring 4-in. in diameter and with an 0.75 in. wall thickness that was welded with a monel electrode designed to impart boron through its coating. The outside gap was held to 0.5 in. with a distortion of but 0.0625 in. After the weld was completed, it was turned in a lathe at ordinary speed with commonly used high speed steel, no unusual precautions being taken. The collar of the weld was originally the same with the exception that some of the Monel from the weld spread over the joint line. The weld was then etched to make the fusion zone more visible. The figures close to the impressions depicted show the distribution of hardness, such as between 160 and 170 Brinell for the cast iron base and between 120 and 132 Brinell for the monel weld deposit. The fusion zone itself was measured with a diamond indentor on the Rockwell "C" scale. Fig. 3b shows clearly where these indentations were made. The figures, converted to Brinell, show also 130 Brinell for the monel and 170 Brinell for the cast iron portions. No harder spots could be found.

When drilling a ⅜-in. hole through the center of the weld and a ¼-in. hole through the fusion line, no difficulties whatsoever were encountered. Furthermore, no difficulties showed up when the ⅜-in. hole was tapped and the welded section sawed with a metal handsaw. The position of each of these operations can be observed in Fig. 3b, which is a cross sectional drawing of the original sample. These results plainly prove that the weld was soft, dense, easily machinable and before etching hardly different in color or appearance than the cast iron.

The welding of cast iron without preheating is generally employed in machine shops where gears, levers, valves, and other important parts are used. This method of repair quite frequently saves not only the machine parts, but prevents undue delays and losses of valuable production time. As such castings are brittle and the danger of breakage is always present, sufficient stocks of the boron type electrode and knowledge of its use can be advantageous to the shop. Of course, a knowledge of the technique of welding cast iron with these electrodes is essential, because each job presents its own problems. The welder experienced in repair work of cast iron will perform many successful repairs on large and small castings with the specially coated boron electrode that with other types of rods might not prove nearly so successful or might even be failures.

Corrosion of Metals in Air

IN reviewing some of the results achieved in corrosion investigations at the National Physical Laboratory, England, W. H. J. Vernon in *Chemistry and Industry* points out that contrary to popular belief a clean iron surface will rust freely in an ordinary room atmosphere of low relative humidity.

Rusting proceeds from sporadically distributed centers having no relation to any factor connected with the metal itself. The number of centers increases with time. Specimens exposed in a muslin cage remained entirely free from rust while control pieces exposed immediately outside rusted freely. Nuclei for the rust centers were therefore provided by disperse particles in the atmosphere. The rate of attack due to disperse particles at low relative humidities falls off as the available unattacked areas become reduced. At increased humidities a point is reached at a relative humidity of 70 per cent when an enormous increase in the rate of rusting occurs.

Specimens were inoculated with particles of ammonium sulphate, others with silica, and others with charcoal and then exposed either to purified air or to air containing a little sulphur dioxide. The relative humidity was gradually raised to 99 per cent in 32 days, at which it was kept for 68 days more. The weight increments due to rusting were measured. Although the system was below saturation for the whole period, the first critical humidity occurred in about 20 days at a relative humidity at 50 to 65 per cent; this indicated the beginning of the attack on the metal with the breakdown of the air formed film. No serious corrosion occurred even with prolonged exposure at this humidity. At the secondary critical humidity, approximately 8 per cent, a relatively large increase in corrosion occurred with the production of ordinary red rust.

Particles of ammonium sulphate are effective in promoting attack with no sulphur dioxide in the atmosphere while charcoal has no intrinsic effect but does become very active in the presence of traces of sulphur dioxide.

No evidence has been found to support the belief that carbon dioxide permits corrosion to go on indefinitely; on the contrary, atmospheric carbon dioxide has a marked repressive effect.

Reclamation of Cutting Oil

By ADAM T. KROL
Chief Research Chemist, Matam Corp., Long Island City, N. Y.

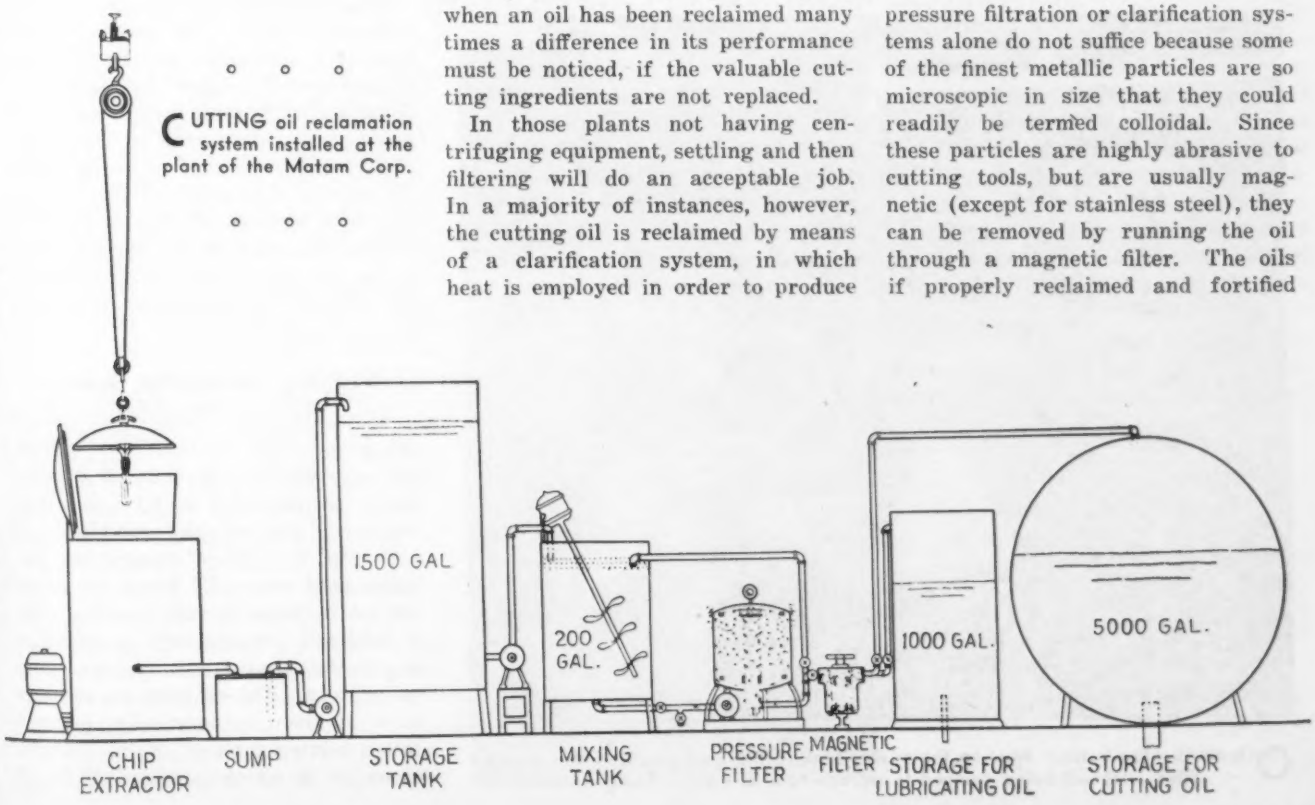
OIL reclamation is not only very vital in normal times but is particularly so in war time because of the savings made possible in raw materials, factory space, tool life and finished products, not to forget the manhours tied up with all these factors and in the production of oil otherwise necessary to make up this loss. As much as 30 per cent of the cutting oil in a machine may be removed with the chips. The amount so removed depends upon the viscosity and the stickiness of the oil and upon the nature of the chips. Fine or "hair" chips remove very little cutting oil; wide and tightly curled chips remove maximum amounts.

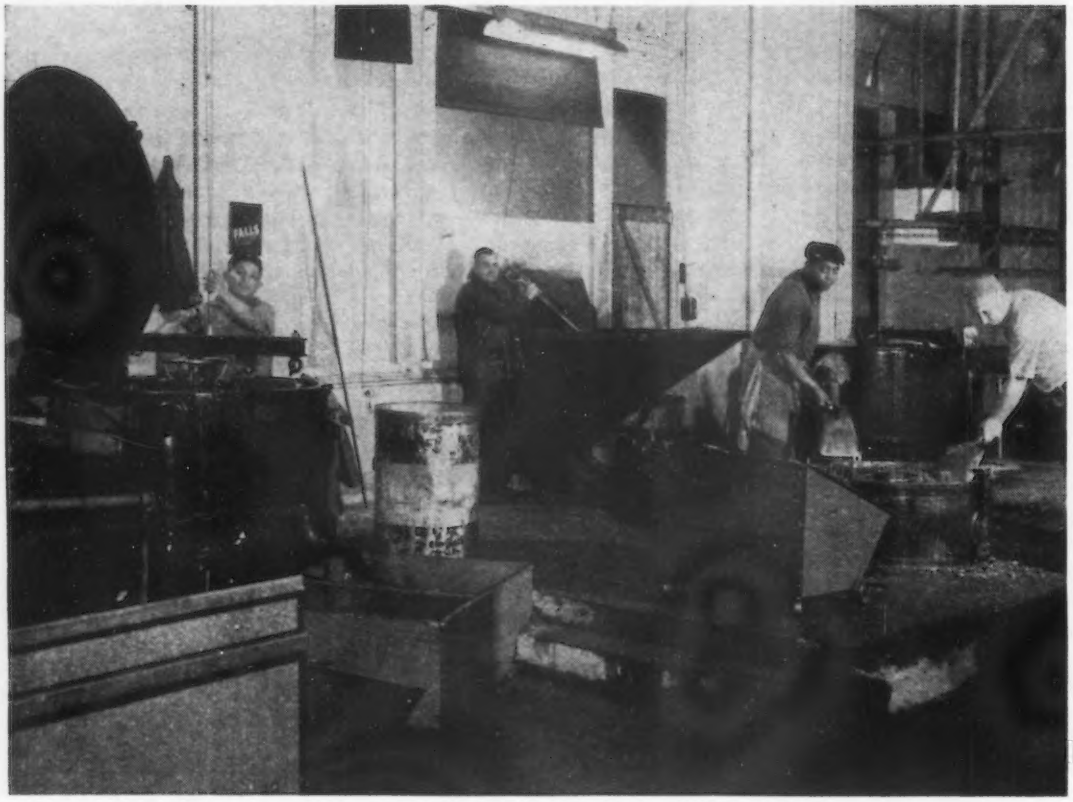
Cutting oils can readily be reclaimed by centrifuging, settling, filtering or by a combination of any one of these methods and subsequently made ready for service after concentrates and disinfectants have been added. As regards replenishment, it is a well known fact that under the terrific pressures exerted between tools and chips some of the most valuable elements in cutting oils are broken down. In good oils, the amount is only a fraction of 1 per cent, but when an oil has been reclaimed many times a difference in its performance must be noticed, if the valuable cutting ingredients are not replaced.

In those plants not having centrifuging equipment, settling and then filtering will do an acceptable job. In a majority of instances, however, the cutting oil is reclaimed by means of a clarification system, in which heat is employed in order to produce a lowering of the viscosity so that settling and filtration can be accelerated. In some instances the cutting oils are recovered from chips taken from the sumps of machines and allowed to drain directly into circulating systems which serve many machines in common. This last method is considered to be merely a cleaning and conditioning process and not a reclaiming one.

For best results, however, even pressure filtration or clarification systems alone do not suffice because some of the finest metallic particles are so microscopic in size that they could readily be termed colloidal. Since these particles are highly abrasive to cutting tools, but are usually magnetic (except for stainless steel), they can be removed by running the oil through a magnetic filter. The oils if properly reclaimed and fortified

CUTTING oil reclamation system installed at the plant of the Matam Corp.





o o o

VIEW of the centrifuging room. One of the baskets is being loaded with wet chips in the middle of the area. Dried chips are dropped into the hopper over a slat conveyor to be taken to storage bins.

o o o

may be repeatedly used many times over.

A typical oil reclamation system operates as follows:

(1) Remove oil from machine sumps and from chip extractors.

(2) Place oil in first settling tank. This drops out the heavy solids and is primarily a place of storage.

(3) Transfer oil to second settling tank and slowly raise the temperature to 180 deg. F. and hold at that point. Finer solids settle out at lower viscosity.

(4) Pass hot oil through a centrifugal cleaner.

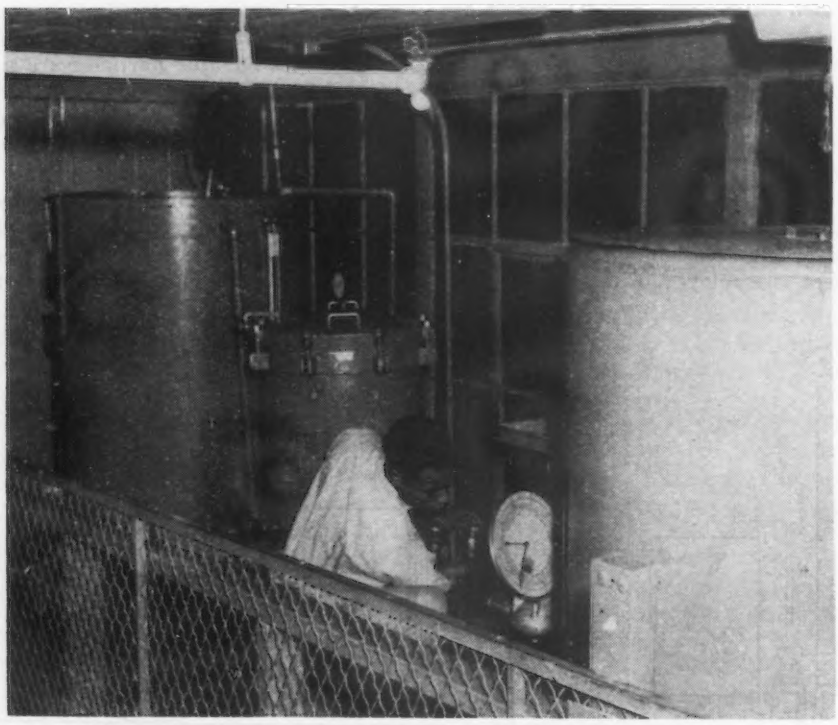
(5) Filter through cloth or through magnetic filter.

(6) Add oil concentrates and any necessary disinfectants.

(7) Cool oil.

(8) Return oil to system.

The Matam Corp. employs a slightly different system. The heating phase is entirely eliminated and by so doing, time is saved in regard to heating the oil to a specific temperature and then having to wait for it to cool sufficiently before it can be returned to the system for service. The following is a resumé of the reclamation system employed by the Matam Corp. on an oil which serves both lubricating and cutting purposes. (See layout of system).



OIL clarification setup. Next to the mixing tank in the background is the pressure filter. Clear oil being pumped to storage tank at right is being metered.

Matam's Reclamation System

After the chips have been whirled dry in a centrifugal extractor (product of American Machine & Metals, Inc.), for about 8 to 10 min., they are lifted out of the machine and conveyed to a chip storage bin for subsequent removal. From the sump the oil is automatically pumped into a 1500 gal. storage tank in order to empty the sump for subsequent chip extractions. The oil from the storage tank is then automatically pumped into a mixing tank of 180 to 200 gal. capacity, in which is added 20 lb. of

diatomaceous earth (Celite No. 535, manufactured by Johns-Manville). A propeller type agitator is used to insure a proper mixture of the diatomaceous earth and oil, because the earth has an added advantage of absorbing moisture and removing unwanted acids, besides brightening-up the color.

After about 3 to 5 min. of agitation, the mixture is then automatically pumped into the pressure filter (Sparkler filter Model 18-S-14, using oil filter paper No. 25, sold by Carl Schleicher & Schull Co.) and by-passed back into the original mixing tank until a gradual and uniform filtering media is built up over the filter paper. When the filtered oil does not show more than 0.025 per cent of *foreign matter present*, which in this instance can be either some free Celite, which is inconsequential, or/and magnetic iron in a colloidal state, *then and only then* the by-pass is closed and the oil passed through a permanent magnetic filter (Ferro Filter Model PQ-5, manufactured by S. G. Frantz Co.) in order to precipitate out the magnetic iron particles. Subsequently the oil is passed into two individual storage tanks.

Once the filtering media has been built up, additional oil can be passed through the filter media until approximately 400 to 500 gal. have been filtered or until such time when the filtering slows up.

From the first tank the reclaimed oil is used directly for lubricating purposes only and from the second tank the reclaimed oil is used for cutting purposes only, after being enriched with the proper proportion of concentrate to replenish the loss of the valuable elements in the cutting oil. An addition of disinfectant is also made to sterilize the cutting oil to prevent dermatosis. (Steridol No. 5, made by C. B. Dolge Co.)

Advantages of System

Some of the specific advantages directly attributable to the oil reclaiming system of the Matam Corp. are:

(1) Due to the fact that the reclamation is done *without any heating*, time and money as well as labor is saved.

(2) Since the oil after reclamation is used for both lubricating purposes and for cutting purposes after properly being enriched with a concentrate, the system is highly economical of oil and a reduced amount of oil need be purchased.

(3) There is an increase in the price per ton obtainable from the scrap dealer in dry, crushed turnings in carload or truck lots.

(4) There is an increase in cutting tool life. Since reclamation of cutting oil makes it economical to change the oil more frequently, this eliminates to a great extent the suspended carbon particles that burn and dull the tools cutting edge. Thus, there is a considerable reduction in the number of hours that a machine has to stand idle while the machine is re-tooled.

(5) There is economy in manhours, as the system is designed to be operated by a small number of men.

(6) Because the cutting oil is sterilized, a definite reduction in hand infections has been noticed and there is a reduction in absenteeism due to dermatitis.

Because the Matam Corp. employs the same non-staining and non-corrosive oil for both lubricating and cutting purposes, it is really comprehensible why a reclamation system is very profitable.

In the above-mentioned reclamation system for a total expenditure of 116 manhours or $106 per day, plus $20 per day for raw materials such as Celite and filter paper, approximately 8000 gal. of oil are reclaimed. With oil at approximately 30c. per gal., the money value amounts to $2400 for 8000 gal. of new oil or of reclaimed oil at a direct cost of $126 per day. With this system a total of approximately *56,000 gal. of oil* can be reclaimed per week very economically.

Movable Jig Speeds Air Intake Fabrication

TO hold the sections of the carburetor air intake duct of the P-39 Airacobra in place while being welded together, Bell Aircraft Corp., Buffalo, devised a special movable jig that clamps the two halves together. This jig holds the work firmly but allows for metal expansion.

In Fig. 1, the jig is shown in clamped position. Welding begins at the far end of the air intake, placed in the jig so that the two halves of the intake form a long V-shaped slot. As the welder progresses toward the forward end of the slot, the metal expansion caused by the heat and the rigidity of the welded part as it progresses forward brings the V-slot together on the open end. While the halves are held rigidly in place, the entire holding jig moves horizontally together, permitting the closing up of this gap between the pieces. Welding speed must be uniform so that the gap between the halves closes evenly.

Conventional procedure would be to hold the two pieces together and tack them, then proceed with welding. When the welding was completed, the part was usually warped and the sections buckled in many places. Straightening of the parts by hand was necessary before they could be used.

The fixture now used has a pair of clamps that run the full length of the seam, set back just far enough from the ends of the metal to give the welder room to work. This firm gripping prevents buckling from metal expansion, eliminates the need for both an extra worker to hold the job, and for tacking before welding.

o o o

FIG. 1—This jig, designed by Bell Aircraft Corp. engineers, firmly holds the two halves of the carburetor air intake duct of the P-39 while welding. Welding starts at the far end, with the halves so placed as to form a V-shaped slot. As welding progresses, the metal expansion closes the slot so that the finished part requires no hand forming.

Tooling With Plastics

By EMRIC W. BERGER

Chief, Manufacturing Research, San Diego Division, Consolidated Vultee Aircraft Corp.

. . . A new thermoplastic material called Toolite has been found to be especially valuable for making hydropress form blocks because of its high compressive strength. It is also applicable to tool jigs and checking fixtures. Mixing the ingredients is like making cake batter and is done on identical commercial equipment.

A YEAR ago when the War Production Board issued its order banning the use of aluminum for tooling, a great part of the aircraft industry was temporarily thrown into a state of chaos. There were a number of substitute materials on the market, but unfortunately most of them were critical materials that could not be obtained or possessed undesirable physical properties and characteristics.

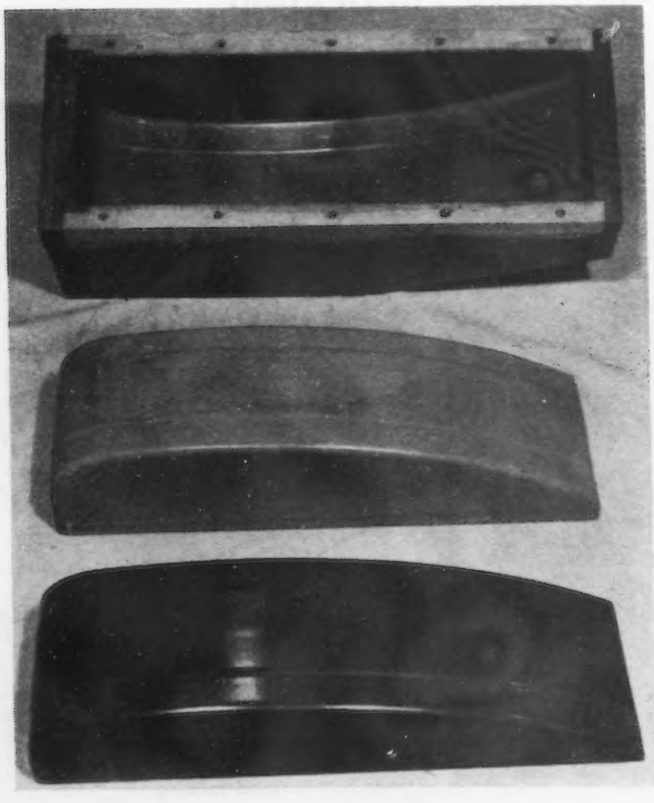
An ever-growing shortage of skilled tool makers for the fabrication of metal-forming dies and punches also demanded relief. When a compound die was needed for the hydropress, it was necessary to make a pattern, a sand mold and a casting; then the casting had to be machined. All of which required the experience of skilled help in order to attain adequate dimensional tolerance control.

At the Consolidated Vultee Aircraft Corp., an answer has been found to many tooling problems in Toolite,* a thermosetting cast resin whose ultimate possibilities are only beginning to be foreseen. Toolite is a homogeneous material with many desirable physical properties not ordinarily found in cast plastics. Foremost among these is an excellent compressive strength of 9000 to 12,000 lb. per sq. in.

** Toolite Plastic and the necessary catalyst are produced by the Adhere Corp., 1220 Maple Avenue, Los Angeles.*

After curing, the weight of Toolite is 77.38 lb. per cu. ft. and the specific gravity is 1.24. The material is inert to ordinary cutting compounds; oil and water absorption tests have revealed no visible effects after immersions in kerosene or water for periods of 24 hr. Although cured at a temperature of 160 deg. F., it withstands a temperature of 400 deg. At greater temperatures, it has a tendency to char, but it will not burn even when exposed to an open flame.

Available in numerous colors, for identifying types of tools, Toolite is opaque and has 100 per cent resistance to various alkaline and acid solutions (except in a few cases, where a surface coloring effect is noted). It is a non-conductor of electricity, and its contraction after curing at 160 deg. F. is only 1/32 in. per ft.



TOP: Female pattern made of wood. Middle and below: Male hydropress form block cast from Toolite plastic in the pattern shown above. The lower form has been coated with a parting lacquer.

Used With Plastalloy

Because of its high compressive strength Toolite has been found to be especially valuable in making hydropress form blocks, tool jigs and checking fixtures. In combination with Plastalloy* for a punch, it has further been found suitable for making female dies and pressure pads for double-action hydropress operations. A window frame part of 0.050 gage 24SO aluminum alloy with a holddown

** Another cast thermoplastic material made by the Plastalloy Co., Burbank, Cal.*

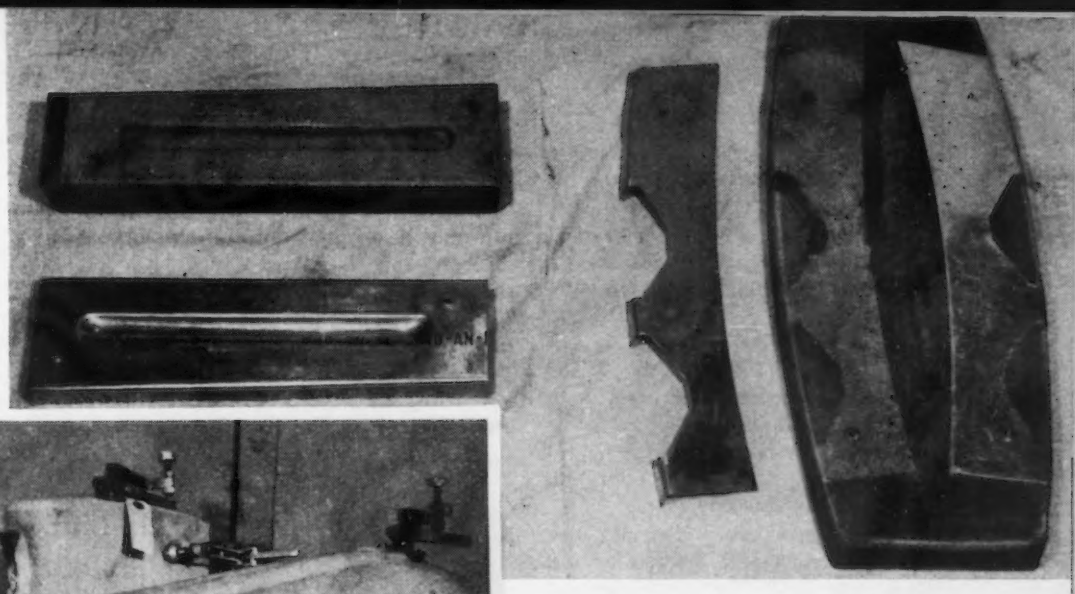
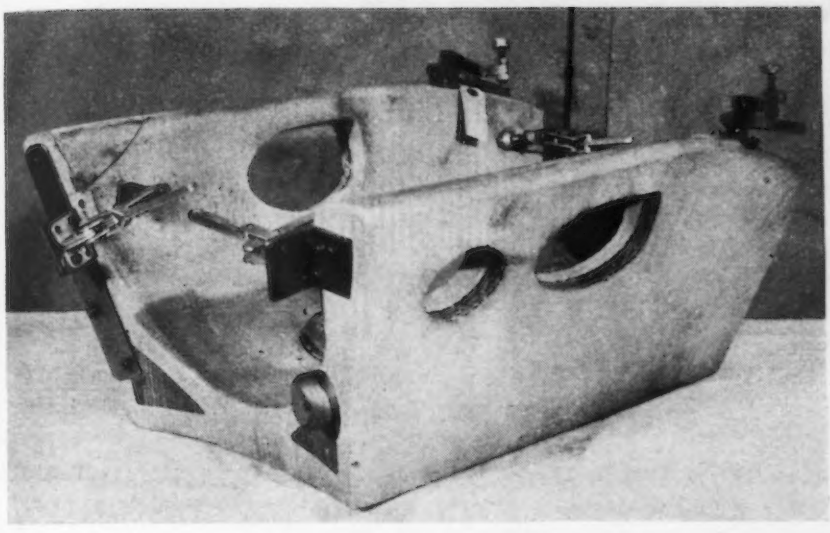
o o o





A Toolite plastic router block, with toggle clamps for holding formed sheet metal part in place.

area of 20 x 30 in. has been successfully formed, with 150 tons on the Toolite pressure pad and 300 tons on the thermoplastic punch and Toolite female die.

The female die and pressure pad of Toolite are cast around the Plastalloy punch. This insures the accurate matching of contours, and eliminates the requirement for scraping in the parts for perfect contact with the sheet metal. The thermoplastic punch has sufficient compressive yield to allow for the metal thickness.

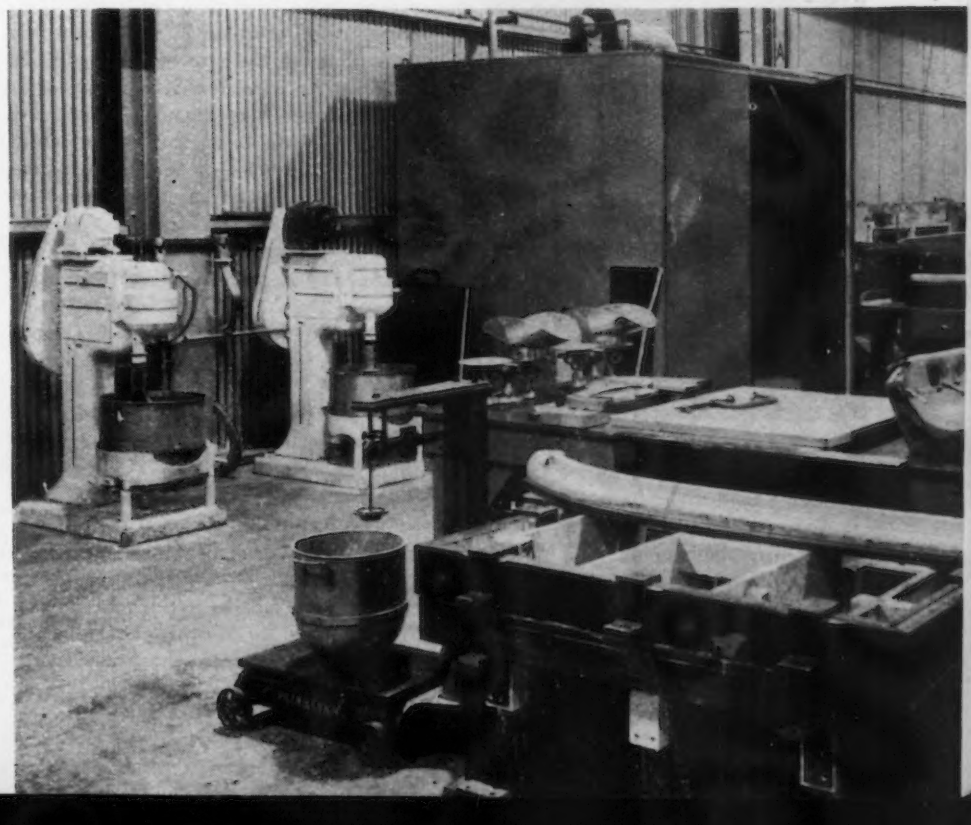
Long, slender aluminum dies have a tendency to curl upwards when used on a hydropress for a comparatively short period of time and this soon causes breakage. At Consolidated-Vultee, Toolite dies have been used for a period exceeding 10 months, some for 0.091 in. thick ribs with pressed beads and lightening holes, without experiencing either warpage or breakage.

High glaze surfaces, which make it possible to cast to accurate dimensions, have made Toolite the choice in building jigs and fixtures. But probably the most interesting and important aspect of all is the fact that the plastic is so easy to work. Even with the most inexperienced help, we find that we are able to make suitable castings of all types.

Speaking in non-technical language,

o o o

THE Consolidated Vultee Aircraft Corp.'s plastic shop. The mixing machines shown in the left background are standard dough mixing machines found in commercial bakeries.



For other articles that have appeared in THE IRON AGE on plastic tooling, see the following:

"Plastics in Production," by Dr. J. K. Leeg, Baker Oil Tools, Inc., Feb. 12, 1942.

"Plastics in Aircraft Tooling," July 2, 1942.

"Plastic Assembly Jigs and Fixtures," by Wm. D. Lewis, Timm Aircraft Corp., Oct. 1, 1942.

"Plastic Punches for Forming Aircraft Sheet Metal Parts," Feb. 18, 1943.

"Steel, Plastics and Zinc Used in Combination Die Sets," by John C. Wright, Vega Aircraft Corp., June 17, 1943.

"Forming Acrylic Resin Sheets with Plastic Dies," by Dr. J. K. Leeg, Sept. 9, 1943.

the entire process is like baking a cake. You mix the batter, butter the pan and cook in an oven. Of course, the actual process is a little more difficult than that, but it is nothing an inexperienced woman could not readily master.

A photograph showing the layout of the cast plastic shop at San Diego is reproduced with this article. Note the mixing machines; these are ordinary cake mixers, each with a capacity of 80 qt. Electrically operated, they have four speeds.

The forms for the tool design are made from wood or plaster, allowing 1/32 in. per sq. ft. for shrinkage and radius of at least ⅛ in. on all corners. The inside portion of each mold is covered with three coats of blue parting lacquer, made by the Scribner & Quinn Co. of Los Angeles, and one coat of Johnson's Glo-Coat wax. When plaster molds are used, they are thoroughly dried at 100 deg. F. in an oven before lacquering.

o o o

POURING the Toolite plastic into a sheet mold formed of laminated plastic sheets held together with bar clamps. The ladle is a standard dough mixing bowl.

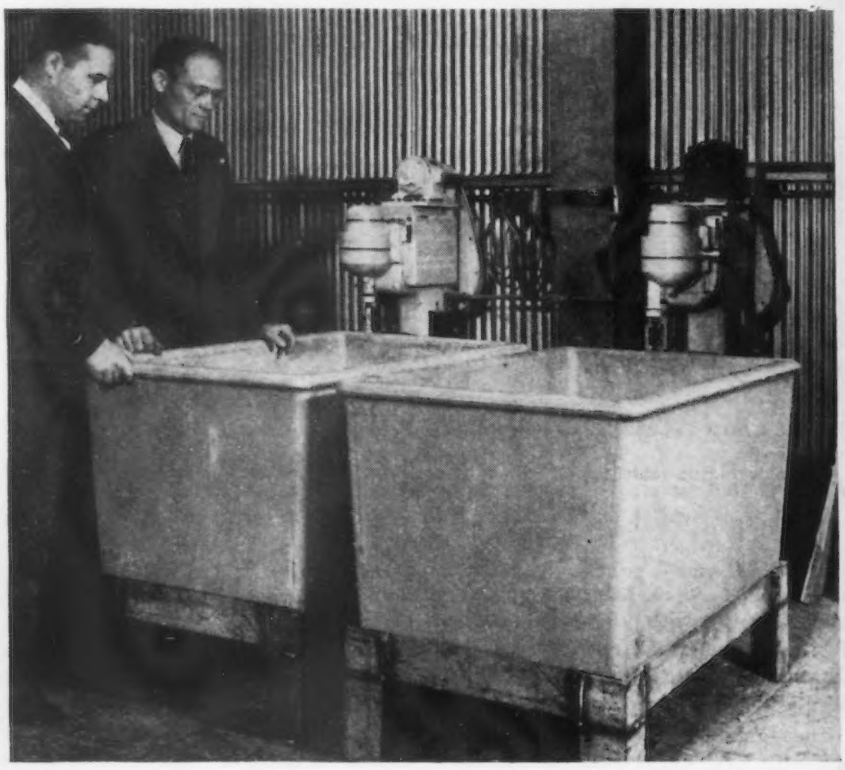
Two 30-gal. drums of Toolite are emptied into the storage tank and agitated slowly in order to keep the plasticizer thoroughly mixed prior to dispensing. Then the required amount (77 lb. for each cu. ft. of volume in the mold) is drained from the bottom tap of the storage tank into the mixing bowl (which is lined with tin) and the catalyst is added (4½ per cent). The mixing machine is operated at the rate of 160 r.p.m. for 15 min.

The mold is filled slowly and allowed to set for ½ hr. in normal atmospheric conditions. Then it is placed in an oven at a controlled temperature of 110 deg. F. for 2 to 6 hr., depending on the size of the mold. If the cast is a male, it is allowed to cook before it is removed from the mold. If female, it is removed while hot. The purpose of this is to insure adequate contraction allowance for separation from the mold.

The mixing tubs and bowls can be cleaned if immersed in a tank containing Turco Airlion No. 81 (6 oz. per gal. of water of 195 deg. F.) for a period of 3 to 5 min. immediately after use.

Experiments are being continued with Toolite for tools other than forming blocks. Tanks 4 x 2 x 2½ ft. have been cast and these are used as acid tanks in the plating department; they have been in service over six months with the acids showing no effect on the plastic. Such tanks can also be used to contain hot alkaline solutions similar to those necessary for spot-weld precleaning at 190 deg. F.

The most recent development in the use of Toolite is that of making blanking dies. To accomplish this, sheet tool steel has been cemented to the Toolite. Although this experiment is rather new, it is felt that it will completely revolutionize the manufacture of blanking dies, saving both materials and manhours.



Acid-proof tanks cast from Toolite plastic.

At San Diego, 3 x 5 ft. sheets are being continuously cast from Toolite from ¼ to 5 in. thick, which are bandsaw cut to size for simple form blocks. Also, waffle boards are being cast of this material to be used for flat piercing dies of approximately the same dimensions.

Solid Rosan* inserts with serrated locking devices are fastened in the forms after curing, then drilled for location pins from templates. This method assures more accurate locations.

When thoroughly cured, Toolite can be readily machined with any ordinary wood-working tools. Its machining characteristics are similar to those of hardwood, and in many cases the surfaces may be finished simply by means of either a planer or jointer.

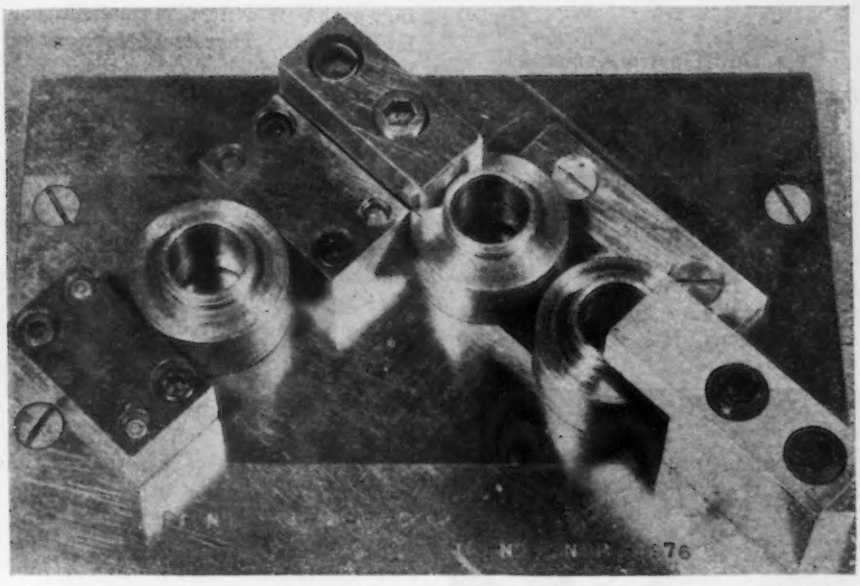
* *See "New System of Locking Studs and Inserts,"* THE IRON AGE, *Apr. 22, 1943, p. 44D.*

Fisher Short Cuts

. . . Hundreds of suggestions for production short cuts made by employees of the Fisher Body Division of the General Motors Corp. have produced noteworthy improvements in operations and work handling. Three typical innovations are shown on this page.

ABOVE

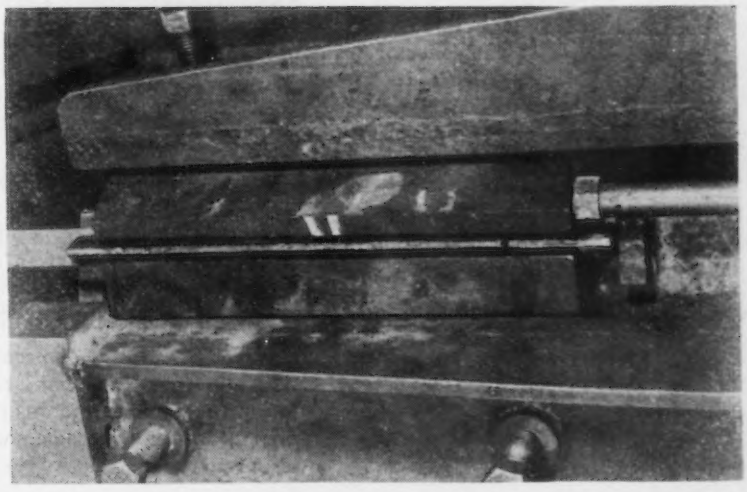
A ROTARY welding fixture was previously operated by push buttons, requiring that the welder lift his shield in order to actuate the rotary device. Jig and fixture department employee William Bolton suggested a foot control for the fixture. Its installation enables the operator to operate the rotary fixture with his foot during the period of welding.



ABOVE

THREE dimensions on bearing cups must be gaged and three snap gages were formerly used for this operation, making possible the checking of 290 pieces an hour. A special detail inspector at ternstedt, Mrs. Helen Bering, suggested a three-in-one gage, consisting of blocks mounted on a plate. The device is shown checking all required dimensions on three bearing cups. Its use makes it possible to check 538 pieces per hr., up 85 per cent from the former level.

o o o



RIGHT

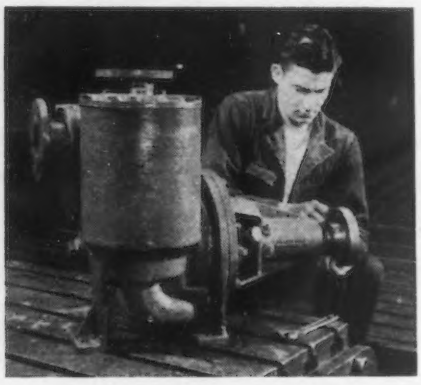
THE welding of vertical seams developed considerable difficulty at Ternstedt with the root bead cracking on the inside surface of the weld during cooling, necessitating extensive grinding of the cracks and rewelding. Welding instructor Clarence Hood suggested a back-up bar with a concave rather than a flat surface, producing a convex surface on the inside of the weld. The weld was strengthened, and at the same time cracking, grinding and rewelding has been all but eliminated.

New Equipment . . .

. . . . Plant Service

A large assortment of unclassified shop equipment is described and illustrated in the following pages

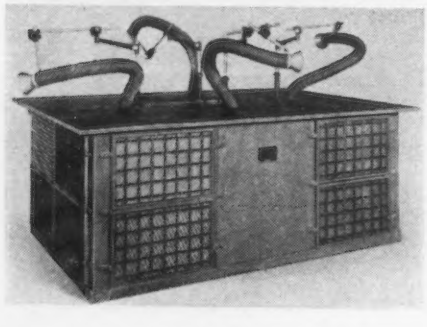
AN automatically controlled valve is a feature of the new type AO self-priming pump announced by *Allis-Chalmers Mfg. Co.*, Milwaukee. The pump is primed as the motion of



the water throughout the pump runner and the volute passage draws air in the suction passage through the impeller and out through the priming chamber. This hydraulic action lifts the column of water in the suction line. The priming valve closes slowly during this process, acting against a spring tension which governs the rate of priming and the static height of the priming suction lift. The automatic closing of the valve prevents water from by-passing back to the suction chamber. The pump impeller has an unusually thick vane with rounded inlet edges, permitting the pump to pass stringy materials and fairly large solids.

Grinding Bench

A FOUR-STATION grinding bench with integral dust collector has been developed by *Schmieg Industries*, 326 Piquette Avenue, Detroit, Mich., for use with portable grinders on non-



hazardous materials. High velocity suction is concentrated at the dust source by means of flexible suction hoses attached to swivel connections. The finer particles are removed by filters while a special plenum chamber is provided for the removal of heavy particles. The unit is furnished complete with fan, four suction hoses and motor with combination starter and push button.

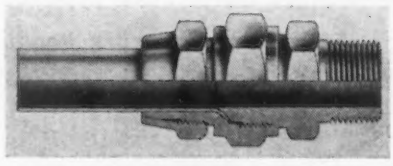
Dust Control Bench

THE type N Roto-Clone bench was developed by the *American Air Filter Co., Inc.*, Louisville, Ky., for safety in burring, filing and flexible shaft grinding of magnesium. The semi-enclosed bench assembly with down draft ventilation through wood grilles is furnished with tool shelf, fluorescent lights and partitions between stations. It is also available in

small individual units which can be located directly in back of magnesium grinding stands. The magnesium dust is precipitated and stored under water. No magnesium particles can pass the drain. Any hydrogen resulting from the reaction of magnesium and water is automatically vented whether fan is stopped or in operation.

Hydraulic Tube Fittings

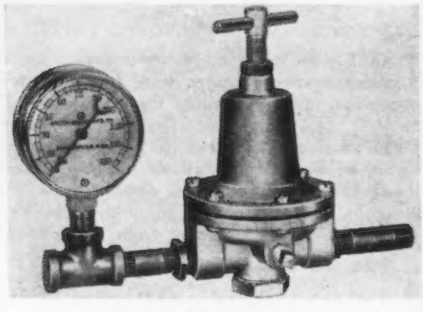
THE *Cotner-Wilkinson Co.*, Logansport, Ind., has announced a line of industrial and hydraulic tube fittings under the tradename of "Collet Grip," which require no threading,



welding or soldering. The double nut series is made for tube sizes ¼ to 2 in. The compression nut compresses the collet nut to the tubing, giving it a firm, permanent, collet-like grip. There is also a single nut series, which retains the double nut features but is simplified for close work.

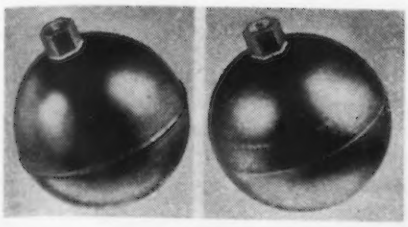
Regulating Valve

THE *Dayton Rogers Mfg. Co.*, 2835 12th Avenue South, Minneapolis, has designed a regulating valve that can be supplied with a pressure gage for reducing the average shop airline to the desired working pressure. They are equipped with a special compound spring mechanism which provides sensitive instantaneous pressure for the maximum airline pressure available. The action of the diaphragm is handled in such a manner that it assures sensitive opening and closing of the ports. It is manufactured in sizes for ¼ and ¾ iron pipe connection.



Hollow Metal Floats

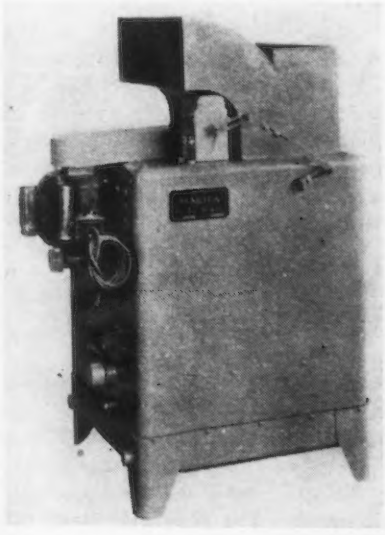
TWO types of corrosion-resistant hollow metal floats for use in steam traps, liquid level controllers and similar float-actuated mechanisms has been developed by *Chicago Float Works, Inc.*, 2330 South Western Avenue, Chicago 8, for service at working pressures up to 300 lb. sq. in. and temperatures up to 750 deg. F. Both types employ monel metal shells. In one the joint is brazed with high tem-



perature silver solder and connection fittings are silver brazed; in the other the shells are welded with monel metal and connection fittings are either silver brazed or welded. Sizes range from 2 to 8 in. diameter, spherical (ball) shape only.

Cooling Equipment

THE Niagara Aero after cooler for compressed air uses the evaporative cooling principle to obtain the lower temperatures and a new design gives greatly increased capacity in compact apparatus. Air, drawn by a fan through a water spray across coils containing the compressed air, is the cooling medium and temperatures within 10 deg. of the wet air temperature can be maintained. The equipment is also applied to gases generated for industrial use. *The Niagara Blower Co.*, 6 East 45th Street, New York 17, has patents pending on this equipment.



Metal Marker

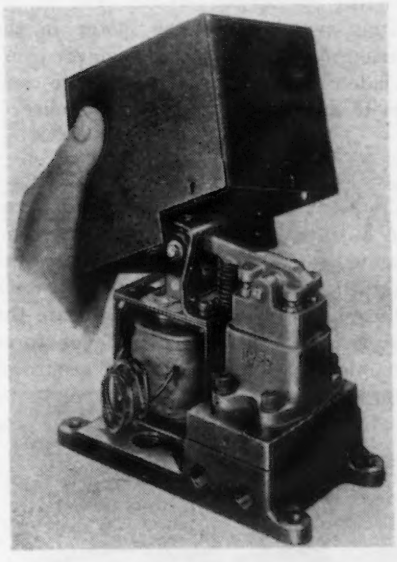
A PAINT stick metal marker for wet, icy or oily metal surfaces is marketed by the *Markal Co.*, 6 East Lake Street, Chicago. The model B is suitable for permanent wet weather markings, taking the place of paint and brush. It is made in several colors, enabling distinctive identification as well as routine piece work markings.

Paint Stick Marker

A PAINT stick marker for use on all cold surfaces is announced by the *Markal Co.*, 6 East Lake Street, Chicago. Designated as Markal N, it is real paint in stick form and produces permanent, fade-proof, weatherproof markings. It is particularly suitable for layout purposes on steel plates, whether bare or coated with zinc chromate or other protective coatings used in pickling.

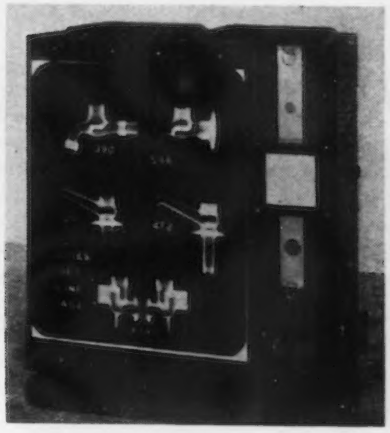
Midget Control Valve

AN unusually compact solenoid air control valve which can be operated at sustained speeds up to as high as 400 reversals per min. has been developed by *Ross Operating Valve Co.*, 6459 Epworth Blvd., Detroit 10, Model No. 835 is a ¼ in. heavy duty 4-way valve for the control of double-acting cylinders; it may also be used as a 3-way valve by plugging one outlet.



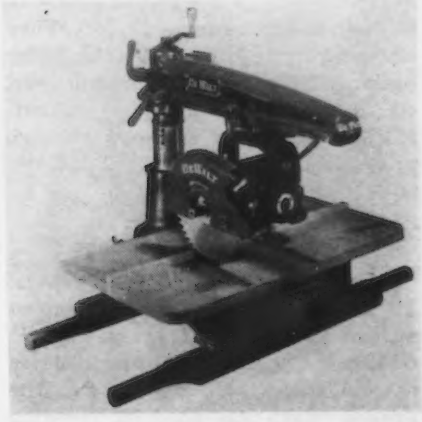
X-Ray Illuminator

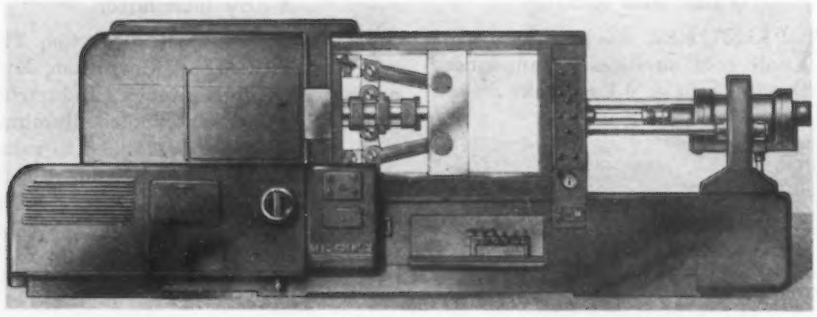
THE *Kelley-Koett Mfg. Co.*, 212 West 4th Street, Covington, Ky., announces a high intensity industrial illuminator with quadrupled illumination. The Keleket is claimed to raise the usable film density from 1.5 to 4.0. The view box is equipped with a Variac control for varying the voltage from 0 to 110 volts. The 14 x 17 in. illuminator permits viewing large films without repositioning. A wet film hanger allows films to be observed immediately after they are developed. A 3-in. spot with four times the intensity of the large front surface permits intensive examination of critical areas on the film.



Portable Radial Saw

DEWALT PRODUCTS CORP., Lancaster, Pa., announces a portable radial saw which will cross cut 14 x 1 or 12 x 3 in. material and rip from 0 to 26 in. wide. Light metals, ferrous and non-ferrous, can be cut when the machine is equipped with metal saw or abrasive wheel. The unit has three radial adjustments. The cantilever arm moves vertically, swings horizontally. It is available in 1½, 2 and 3 hp. sizes.





Die Casting Machine

REED-PRENTICE CORP., Worcester, Mass., has developed their large capacity 3G high pressure cold chamber die casting machine equipped with Vickers 2000 lb. pressure hydraulic pump system. The movable die plate mechanism can be adjusted through electric motor and screws to accommodate different thicknesses of dies. Machine can be operated either manually or semi-automatically.

Lubricating Oil

DEVELOPMENT of a new detergent type lubricating oil which will reduce wear and assure engine cleanliness and oil stability for low speed diesel engines is announced by *Standard Oil Co. of Indiana*, Chicago. The detergency results from the use of an additive which is both a detergent and an oxidation inhibitor. A film of the oil coats carbon and dirt, prevents particles from sticking and holds them in suspension until they are trapped by a filter or drained from the engine.

Packing List Protector

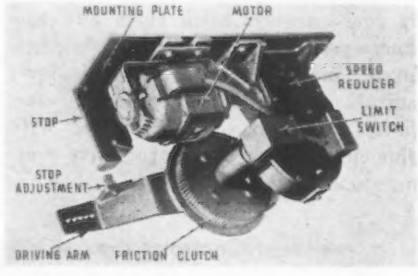
PACKING list protectors, fabricated from asphalt plyboard, have been developed by the Philip Carey Mfg. Co. and distributed by the *Western Paper Goods Co.*, 1224 West 8th Street, Cincinnati. The covers are available in 6 x 8, 8 x 11 and 10½ x 13 in. sizes and in a range of colors. They are adequately dished to take bulky packing lists, assembly instructions, etc., and are firmly affixed to the outside of the crates or boxes through pre-punched nail starters.

Synthetic Rubber Sponge

MANUFACTURE of a general purpose synthetic rubber sponge is announced by the *B. F. Goodrich Co.*, Akron. It is made in three densities, soft, medium and firm grades. Each has good oil resisting properties and can be made into slabs, cord, tubing or in almost any other molded shape. Slabs 24 x 120 in. can be made in thicknesses of ⅛, 3/16, ¼, ⅜ and ½ in. and 24 x 60 in. slabs in ¾ and 1 in. thicknesses.

Electric Door Operators

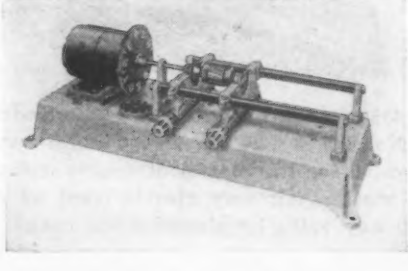
MODELS V and VR electric operators for operating one, two, three and four-leaf inward swinging



doors and for one-leaf outward swinging doors have been brought out by *Barber-Colman Co.*, Rockford, Ill. If the door is jammed, the clutch will slip only until the drive shaft reaches the end of its normal stroke, that is, the limit switch stops the motor in the usual manner. The unit is never overloaded longer than is required to complete an opening or closing stroke.

Balancing Machine

AN extremely sensitive and accurate balancing principle is embodied in the Dy-Namic balancers designed by the *Bear Mfg. Co.*, Rock Island, Ill. The machines indicate the disturbing centrifugal force or force couple with a high degree of accuracy. Both the angular position and the value or amount of unbalance is shown at the same time. The balancing machine reveals whether a static or dynamic unbalance, or both, are present without reversing ends of the body being balanced. A variety of models range from bench models to large floor and pit-type models for balancing such rotating parts as armatures, fans, blowers, fly-wheels, hubs, drums, propellers, gears, impellers, pulleys, wheels, rotors, etc. weighing from 6 oz. to 1000 lb.

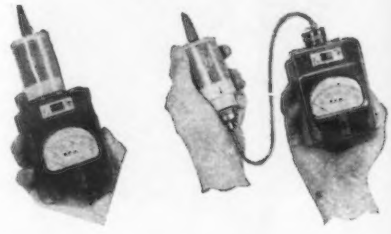


Air Blaster

A LARGE volume of air is directed in a straight line into out-of-the-way corners and dead air spaces by the air blaster developed by the *Chelsea Fan & Blower Co., Inc.*, 1206 Grove Street, Irvington, N. J. The unit consists of a heavy gage welded steel housing, mounted on an adjustable pedestal which may be tilted 60 deg. up or down. It is driven by a direct connected, ball bearing motor. Three sizes are available—18 in. ¾ hp., 600 GFM motor; 24 in. 1½ hp., 9000 CFM motor; and 30 in. 1½ hp., 11,000 CFM motor.

Electric Tachometer

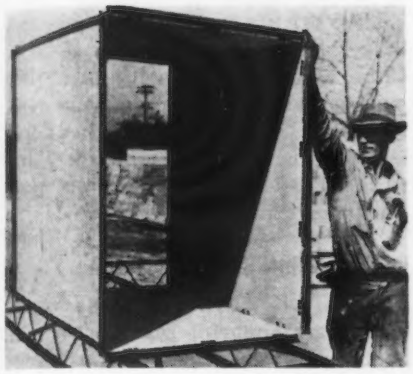
A SELF-ENERGIZED tachometer that can be used either as a hand type or separable type is announced by the *Ideal Commutator Dresser Co.*, 1925 Park Avenue, Sycamore, Ill. It consists of a small generator, coupled electrically to an elec-



tric meter. The generator itself consists of a small permanent Alnico magnet rotor mounted on precision sealed ball bearings. The meter is a rectifier type, capable of withstanding a momentary overload up to four times the maximum speed indication without damage.

Panel Connectors

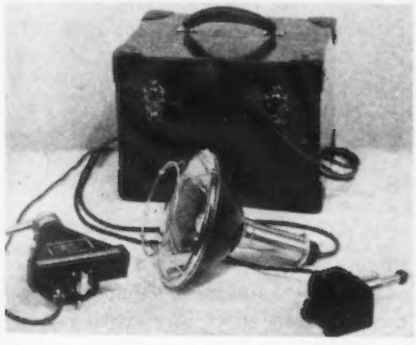
THE panel connectors introduced by *Dravo Corp.*, 300 Penn Avenue, Pittsburgh, are a method for assembling non-metallic ducts for heating and ventilation to conserve strategic materials and to meet requirements for non-corrosive ductwork. The units are said to require only three basic elements, which come in



various gages of metal, depending on the perimeter of the duct required. Panels are secured by clips placed on 12-in. centers and so shaped as to permit the non-metallic panels to be fitted snugly between them and the member.

Balancing Equipment

A VIBROMETER which measures vibration amplitude directly and a stroboscope which gives a direct visual reading of high spot or phase angle has been added to the Davey portable balancing equipment for dynamic balancing of machine parts of



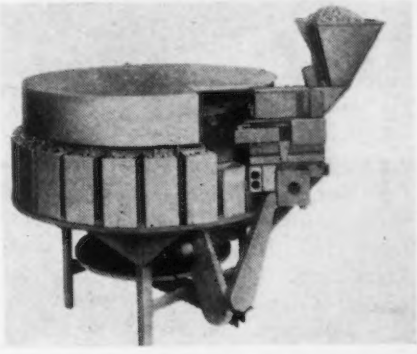
all sizes in their own bearings or in bearings built for the purpose. A remote control switch is mounted on the vibrometer. The unit is built by the *Vibroscope Co.*, 6 East 39th Street, New York 16.

Fluorescent Starter

WESTINGHOUSE ELECTRIC CO., East Pittsburgh, Pa., has developed a fluorescent starter that preheats the cathodes in the usual manner. It also interrupts the circuit when the lamp becomes deactivated or reaches the end of its life. A thermal switch is in series with the timing switch, and when the lamp fails, the starter makes a few attempts to put it in operation. The resultant heat brings the thermal switch into play, which then permanently opens the lamp circuit. The starter is fully automatic and is available for 40 and 100 watt lamps.

Length Sorter

A MACHINE which automatically sorts to length dural, brass and steel machine screws, bolts and rivets is announced by *Tubin Engineering & Mfg. Co.*, 764 San Pedro Street, Los Angeles 14. The machine delivers from 85,000 to 100,000 sorted parts in 8 hr., sorting to ⅛, 1/16 or 1/32 in. variations in lengths. Twenty-four different lengths can be sorted at one time into separate receptacles, with a throw-off receptacle for lengths not set for sorting on the machine.



Fluorescent Fixture

FOR areas where high levels of illumination are required or where high-bay mounting is necessary, *Sylvania Electric Products Inc.*, Salem, Mass., announces its new model HF-235R industrial fluorescent unit, which uses two 100-watt lamps. The fixture may be suspended by direct chain suspension, direct conduit mounting, messenger cable-clamp assembly or surface mounting with bolt or lag screws. They are suited to individual or continuous-row mounting.

Transparent Lunch Box

A LIGHT-WEIGHT, transparent Lumarith plastic lunch box, distributed by the *Irwin Corp.*, 27 West 20th Street, New York, cuts inspection time because it permits examination of the contents without opening the kit. Transpecto is standard size and is equipped with a vacuum bottle holder. One type has a transparent body and colored bottom and ends, and another has a colored body and bottom with transparent ends. Lumarith is a product of Celanese Celluloid Corp.

Reflectorizing Material

THE Minnesota Mining & Mfg. Co., St. Paul 5, has developed Scotchlite for signs, pointers and warnings. This reflectorizing material consists of tiny beads of clear glass firmly set in a flexible weatherproof backing. It comes in rolls of 12 to 24 in. wide and can be cut to any shape or design and then painted or silk-screen processed.

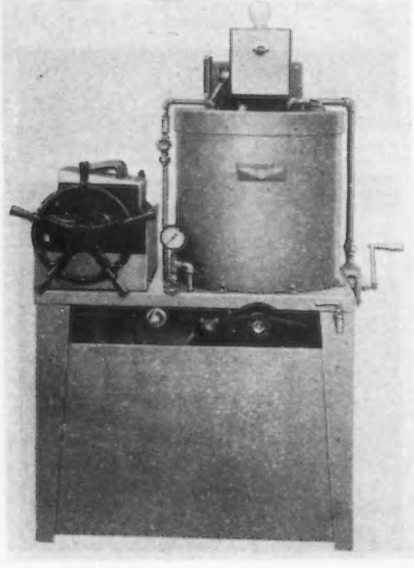
Safety Goggle

THE F3142 Ful-Vue safety goggle with 6.00 curve clear Super Armorplate lenses designed to fit the smaller features of women is announced by the *American Optical Co.*, Southbridge, Mass. It is made in 42 mm. eye size and bridge sizes in 19, 21 and 23 mm. The goggle combines efficient eye-protection against flying objects with all-round visibility, com-

fort and appearance. The double-braced bridge is designed for long life under hard usage. Earpieces have perspiration-proof insulation.

Oil Reclaimer

A SMALL capacity lubricating oil reclaimer, designed for small plants and organizations having their own fleet of trucks and motor cars, is being manufactured by the *Youngstown Miller Co.*, Sandusky, Ohio. With a capacity for purifying eight gallons of dirty oil in 70 to 90 min., it



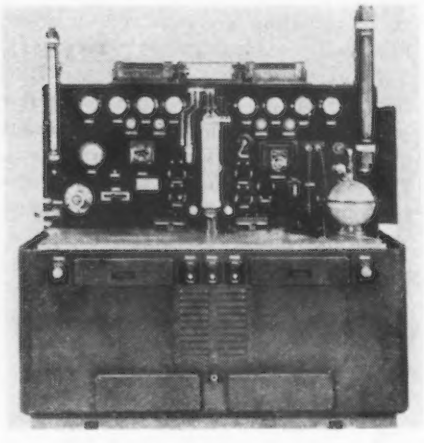
is claimed the Model A-8 will handle 2500 gal. of waste lubricating oil per year when operated only once a day. The machine has a two-stage filter press, is semi-automatic, operating under thermostatic control, and utilizes common refinery earths. Seven sizes are available.

Portable Test Stand

TO test the hydraulic systems of airplanes and the component parts comprising those systems, Model HTS3EM HydrOILic portable test stand has been put on the market by the *Denison Engineering Co.*, 1186 Dublin Road, Columbus, Ohio. The suction and pressure lines of the hydraulic system of the airplane are disconnected from the pump and connected to the test stand. The volume of flow is adjusted to any desired point between 0 and 3.2 gpm, and the test stand relief valve is set at a higher pressure than the hydraulic system's relief valve. The hydraulic system is then tested and operated in the same manner as under flight conditions. The stand is electric motor driven. Fluid is supplied from either the airplane or tester reservoir. The tester's working pressures are adjustable over a range of 500 to 3000 psi.

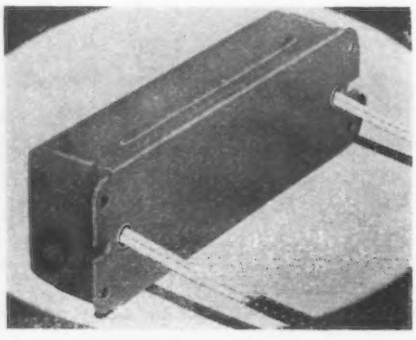
Test Benches

TWO models of test benches have been built by *Hydraulic Machinery, Inc.*, 12825 Ford Road, Dearborn, Mich. T-116, arranged for pressures up to 2000 lb., may be used for testing short lengths of hose or tubing, cylinders, etc. T-110 was built for testing most anything in the field of hydraulics.



Fluorescent Lamp Ballast

A NEW line of ballasts with leads coming out through two bushed holes at each end of the base plate is announced by *General Electric Co.*, Schenectady. They can be mounted completely exposed atop a narrow,



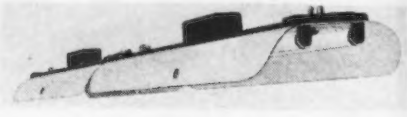
shallow wiring channel just wide and deep enough to enclose the leads. Because of their exposed location, they will operate in lower ambient temperatures. The ballasts are available in 40-watt Tulamp and three lamp ratings and 100-Watt Tulamp and Forlamp ratings.

Whiteprint Developer

A TABLE model for dry developing whiteprint reproductions of engineering drawings and tracings has been made available by the *C. F. Pease Co.*, 2601 West Irving Park Road, Chicago. The "700" is a developer only, with two forward speeds, 4 and 8 ft. per min., and can be used in conjunction with any blueprinting or direct process printing machine using dry direct process paper. It is made in two sizes, 42 and 54 in.

Industrial Fluorescent Lighting

DESIGNED for easy continuous strip installation, a new lightweight fluorescent luminaire with one-piece, double-length hood and two full size reflectors is announced by *Westinghouse Electric & Mfg. Co.*, East Pittsburgh. Available for use with four or six 40-watt or four 100-watt Mazda F lamps, the new type F N C



luminaire is the equivalent of two conventional units. The hood is fabricated from sheet steel with all ballasts, lamp holders and starter sockets mounted and wired as part of the channel assembly. Sliding hangers permit suspension from any part of the hood. The moisture-resistant, non-metallic reflectors are covered with a multi-coat polymerized finish which provides a reflection factor of 85 per cent or more.

Fluorescent Lamp Starter

AN average rated life of three years was announced for a fluorescent lamp starter by *General Electric Co.'s* Appliance & Merchandise Dept., Schenectady. The Watch-Dog is a manual-reset type for 40-watt lamps. It features precision lamp starting and dead lamp lockout.

AN INTRICATE DIE-PRESSED ALUMINUM FORGING

by REVERE

Weight: 1¾ lbs.; length: 9"; extreme width: 6"

The intricate die-pressed housing pictured above is really quite a job. It is typical of other difficult die-pressed aluminum forgings that Revere can supply in a wide variety of shapes and weights with a wide range of applications. The aviation industry alone has eagerly availed itself of these strong, close-grained, intricate die-pressed aluminum forgings and will attest their economy and utility. Revere forgings are also available in copper, various copper-base alloys and magnesium.

Revere will be glad to give you technical advice—*without obligation*—on any special problems that you may have in the field of die-pressed forgings. Write Executive Offices.

FREE! A 54 page manual, "Revere Copper and Copper Alloys—Technical Information for Product Designers," with 106 graphs relating to physical and metallographic properties under varying conditions; also, a new, easy-to-read chemical and physical properties chart, with pertinent illustrated information on Revere manufactured forms and welding technique. A complimentary copy sent you upon request. Address: Executive Offices.

Assembly Line . . . STANLEY H. BRAMS

• Auto dealers seek distribution control of surplus automotive Army goods when war ends . . . Postwar auto rationing for period to relieve retail demand favored . . . Dodge-Chicago plant ships first air engines.

DETROIT—Last week saw the cream of the nation's car retailers, members of the National Automobile Dealers Association, troop into Detroit, overflow all available hotel space, plan for the near and long-term future, and leave behind them the very definite impression that any worries over the war's effect on the distributing organizations of the automobile companies have been overdrawn.

Of the 42,000 retail outlets in existence when the war began, approximately 10 per cent have retired, a few because of insolvency, others because of disinterest and service participation. Profitable service work and exceedingly productive used car selling accounted for the good showing. Most of those gone from the scene are the fringe city dealers. The big volume metropolitan operations are continuing, and so are the franchises in the small towns.

This convention developed some interesting viewpoints of definite concern to the manufacture. For one thing, an end to the war and a resumption of new car production will bring into focus the same problems in factory-dealer relationships which existed before the war. There will be continued demand for more liberalized franchises, for greater protection in sales areas, for fewer volume guarantees, for more protection against cancellation of agreements. A fair segment of membership within the association, concentrated mainly in the east, still leans to the idea of legislation as a method of obtaining such concessions, but the majority appears to rely more on conferences than legislation. However, the dealers took home with them copies of licensing laws in the states, so that after reading them, learning the advantages and disadvantages, they can develop a nation-wide sampling of sentiment to determine just how far the N.A.D.A. may want to go in seeking a uniform licensing law in all states.

Many of these state laws already in effect are definitely severe, and their application to automotive merchandising may prove preludes to applications to other forms of distribution. For instance, in Rhode Island all factory representatives of automobile companies are licensed, and their licenses are revokable when dealers submit evidence of coercion by them. In Wisconsin the factories themselves are licensed, but here the law is a boomerang, because any suspension of license due to a violation of the law in one instance immediately throws all other dealers in Wisconsin handling that merchandise out of business. In Iowa, franchises are partially protected by the simple expedient of non-licensing of any new agreement for 90 days in an area where an old franchise has been cancelled.

THE dealers are quite determined to be the channeling means for disposal of surplus automotive equipment. Speakers pointed out that at the end of the first world war surplus Army trucks were sold to the French, were never paid for, and ultimately found their way back to these shores for resale at undercut prices in competition with this nation's auto dealers. The dealers applauded a program which would take automobile parts and equipment in Army hands, expected to reach $2,000,000,000 at the end of the war, and distribute it through a commission created by Congress, consisting of half government and half business members. Selling would be at rates calculated not to disrupt then-current manufacturing and sales, at prices permitting a reasonable profit for the handlers and a fair recovery for the government, and always through established trade channels.

The dealers indicated great disapproval of means of current disposal of a reported 10,000 trucks turned over by the Army to treasury procurement and offered at open bidding. The dealers said bids were offered at ceiling prices by black market operators, making it impossible for litigimate dealers to obtain the trucks with margin to allow for reconditioning costs.

There was some belief that the number of automobile outlets in the post-war period would be larger than ever before, but that the number of actual direct factory dealers would be smaller. In other words, many of the dealers expected an extension of the practice of franchising dealers who in turn would appoint associate outlets and merchandise a considerable share of their stock through them.

The dealers reported that parts for cars of 1936 and earlier vintage were becoming constantly harder to obtain, as were special truck parts, like axles, etc. They were told by their Washington officials that cuts in the lead content of gasoline were likely to come within the next few months, and that the A coupon value on the Pacific coast would probably be reduced by one or 1½ gal. between now and Spring.

A sentiment was notable in favor of car rationing for a limited period after the war, for the simple reason that it would relieve the outlets of pressure for deliveries put on them by a car-hungry public. But, in contrast, the dealers' viewpoint on price control was that it should not be applied at all to new or used cars or trucks, now or after the war.

The dealers were furnished these projections on truck production this year: for medium trucks 7 per cent of the 1944 total will be produced in the first quarter and 29, 33 and 31 per cent, respectively, in the subsequent quarters. For light heavy and heavy trucks production will run 23, 24, 27, and 26 per cent by successive quarters this year. Dealers hope to obtain the same proportion of these completed units as they had in the last full peace year, but said some manufacturers plan to do distributing through branches entirely, leaving it to the field offices to determine where the trucks shall go, while others plan to ship to dealers only when those outlets have certificates on hand from would-be purchasers.

NOT the least interesting of the developments at the dealers' meeting was the appearance of Henry Ford II at a full session. The 26-year-old son of the late Edsel Ford

. . . and you cannot escape it!

This "Frozen-Action" photo pictures a force that is shaping the destinies of all mankind — now and for generations to come.

To our enemies it is a dreadful secret force that will one day bring them crying to their knees. Secret to them . . . because they have never fully understood it. Their warped minds could not possibly realize the extent to which American industry has mastered *the art of cutting and working metals on a vast scale.* Our enemies can neither equal nor escape this force — bred by generations of free enterprise.

To Americans, this force is the secret which has brought about the highest standard of living the world has ever known. When peace comes, it will be a key factor in building a better world.

Our picture shows Pratt & Whitney milling cutters at work. And there's a secret *here* — too. If you already use Pratt & Whitney small tools you know about it . . . about their keen cutting edges, long life, and dependability. If you are not yet a user of these fine tools — now is a good time to find out how they can help cut your costs in the highly competitive civilian production days which lie just around the corner. Get in touch with the nearest P&W branch office, where you will find expert engineers ready to co-operate by offering sound, economical solutions to your metal working problems.

Shown are two Pratt & Whitney plain milling cutters at work. The line of top quality small tools made by Pratt & Whitney includes a complete line of TAPS, DIES, REAMERS, GEAR CUTTERS, MILLING CUTTERS, DRILLS, ARBORS, PUNCHES, THREADING TOOLS, METAL SLITTING SAWS . . . and many others. Each one is made to the well known Pratt & Whitney standard of accuracy.

PRATT & WHITNEY

Division Niles-Bement-Pond Company

WEST HARTFORD • CONNECTICUT

was introduced as the vice-president of Ford Motor Co. in charge of sales. The young Ford was generally agreed to have made an excellent impression in this, his initital appearance as an official of the company founded by his grandfather.

Speaking in Chicago last Saturday, K. T. Keller, president of Chrysler Corp., revealed that the Dodge Chicago plant has shipped its first run of production engines to the Air Forces, and indicated that the plant is expected to be in substantial production of these motors "before many months."

Output, Mr. Keller inferred, has been somewhat delayed by still-continuing design changes in the engine. The power plants being made are those which will drive new superbombers; at monthly peak production their horsepower will aggregate more than the output of "two Boulder Dams, plus Grand Coulee and Bonneville put together."

Up-to-date equipment figures were provided by Mr. Keller in his address. He said the plant will utilize about 8000 machines, requiring approximately 1,200,000 tools, jigs, dies and fixtures, with gages and small tools bringing the total up to nearly 5,000,000.

On the post-war score, Mr. Keller renewed the automotive industry's plea for development of a policy now for cleaning up the war plants. He outlined a six-point program which he said could be undertaken now, as follows: (1) Determination of what the government is going to ask industry to maintain in the form of physical facilities to supply the armed forces in preserving peace after the war. (2) Decision which of these industrial units shall be retained in operating condition by present custodians and operators. (3) Decision what facilities the government will wish to retain itself for the protection and maintenance of peace. (4) Decision what government equipment and materials in its own or privately owned plants the government will wish to dispose of. (5) Listing and earmarking of them for sale under a sensible pricing and disposal procedure, then selling of them now under conditions that will let them stay where they are as long as the war needs them. (6) Finally, arrangement for the prompt removal of machines and materials that will be in the way of peacetime production when the war ends.

DPC Will Move Idle Stack to Texas

• • • **Lease agreements** for the erection of a charcoal blast furnace and byproduct plant at Rusk, Texas, have been completed between the Defense Plant Corp. and McCrossin Engineering Co., New York. DPC will appropriate $2,379,000.

The project comprises the removal of an idle blast furnace and sintering plant from Pembroke, Fla., and of a complete carbonizing plant and charcoal byproducts recovery plant from Wells, Mich.

Most of the equipment required for this plant is now idle and only a relatively small proportion of new equipment and supplies will be required.

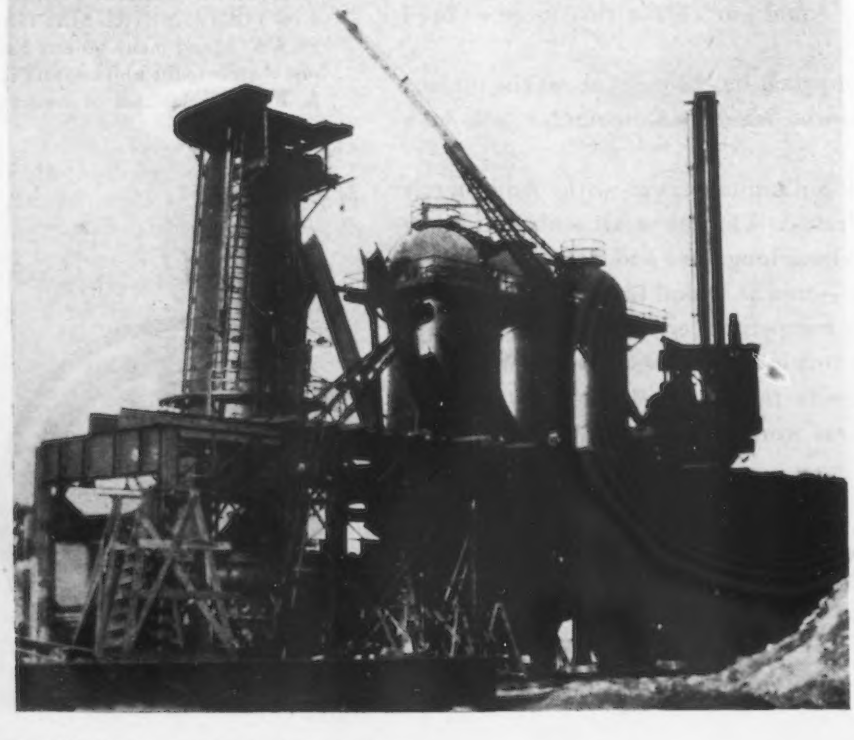
The blast furnace now standing idle on a phosphate quarry in Florida was originally built to make elemental phosphorous from phosphate rock which is abundant at Pembroke. The process was not feasible and was, therefore, abandoned. This plant has a ground plan of about 210 ft. by 230 ft. and will be so re-erected as to be integrated with the charcoal plant, furnishing the fuel, and with the central power plant that will use part of the blast furnace gas for raising steam. Only a new hearth jacket is necessary. No changes are contemplated in the sintering and carbonizing plants.

Ground plans for the ore crushing and cleaning plant have not yet been made and must await the detailed survey of the proposed plant site, and the general plan of the integrated plant.

The new plant will make 100 tons of charcoal pig iron daily and will furnish, in addition, charcoal, glacial acetic acid, methanol, sintered iron ore and blast furnace slag for mineral wool.

Col. E. F. McCrossin, president of McCrossin Engineering Co., DPC's agent in design, engineering and construction, has been active since 1925 in the exploration and development of the iron ore deposits of Northeast Texas and his original reports and maps were incorporated in the U. S. Geological Survey of the "Brown Iron Ores of Eastern Texas." Ralph H. Sweetser, author of "Blast Furnace Practice" and numerous articles in THE IRON AGE, is consulting engineer.

FROM PEMBROKE, FLA., to Rusk, Tex., goes this idle blast furnace and sintering plant. When completed, 100 tons a day of charcoal pig iron will be produced, in addition to glacial acetic acid, methanol and wood tars.



Use the Stainless Strip that **SIMPLIFIES** Production Problems

PRODUCED ON AUTOMATICS—Notwithstanding the high tensile strength required in this material, its high ductility makes possible complete fabrication on special automatic machines.

REVERSE DRAWS NO PROBLEM—Uniform Carpenter Stainless Strip made possible this difficult reverse drawn part. Danger of splitting around the edge of the inside hole was entirely eliminated.

PROOF OF DEEP DRAWING QUALITIES—Here's an example of the way in which Carpenter Stainless Strip can be deep drawn. Easy working qualities, plus the close tolerances to which the strip is held, effect savings in deep drawing costs.

When you choose a Stainless Strip today, you want one that blanks and forms readily, keeps output at a high level, and is easy on your tools and dies.

Carpenter Stainless Strip gives you that kind of performance. This Strip blanks as clean as a whistle, yet has ample ductility for fast, easy forming. And Carpenter Stainless Strip works the same, coil after coil, as a result of uniform temper.

In thousands of press rooms, ductile, bright-finish Carpenter Stainless Strip is smoothing out wartime production difficulties. And some of the same manufacturers who are side-stepping fabrication troubles with this Stainless Strip today, are planning on it to get greater Stainless production economy in their post-war products.

Investigate Carpenter Stainless Steel now! Get in touch with any of the Carpenter offices below, and put your problem up to your Carpenter representative. He will help you make your Stainless operations more economically productive now and in the future.

This handy Carpenter Stainless Steel Selector Slide Chart will help you quickly spot the right grade of Stainless to meet your requirements. It provides data on working properties, physical characteristics, etc., of each grade of Stainless. A note on your company letterhead will bring you a Slide Chart . . . free to Stainless users in the U.S.A.

• Report of Smith (House) Committee charges War Labor Board committed illegal and unconstitutional acts . . . War power of President and Congress discussed, with latter's said to be more comprehensive.

WASHINGTON — The Smith (House) Committee report submitted to Congress last Thursday says that there "ought to be a law" to prevent the National War Labor Board from continuing its clearly illegal and unconstitutional activities.

The report which proves in a masterly fashion through citing tens of Supreme Court cases that something should be done by Congress to curb the War Labor Board's highly arbitrary and biased actions in favor of labor fails to say what good more law will do in the face of the board's willful disobedience to perfectly valid existing laws.

Perhaps the board's failure to do this was a studied effort to provoke comment and action not only by members of Congress but by the public.

The question raised, of course, is why the public permits the executive branch of government to be derelict in carrying out the mandates of Congress. If the executive branch of government fails to carry out the laws made by Congress and ignores the Constitution, the courts and the Congress are powerless.

The only remedy is the election of those who will obey the will of the people enforcing the laws enacted by Congress.

When the gravity of this situation will percolate to the hinterland and engender positive action at the polls, is unpredictable. Perhaps the public is already aware of this danger to representative government, but will hesitate to choose a new President in the next national election because of the war.

THE report charges that WLB committed the following illegal and unconstitutional acts:

1. Ordered the check-off and the closed shop contrary to the National Labor Relations Act and War Labor Disputes Act, the Constitutional and numerous decisions of the Supreme Court, other federal courts and the National Labor Relations Board.

2. Enforced a new legal doctrine that it (WLB) has the power and authority to compel the parties to execute a contract to do anything that the parties might voluntarily do, irrespective of whether there is any legal or contractual obligation on the parties to do so.

3. Has not confined itself to labor disputes in war industries but has assumed jurisdiction over all types of business, no matter how remotely they may be removed from any connection with the war.

4. Adopted a policy that in the determination of a wage dispute the question of the financial status or ability to pay of the employer is irrelevant and immaterial and that any employer whose business does not justify the payment of what the board in its judgment or generosity regards as a decent standard of wages is economically inefficient and ought not to be permitted to remain in business.

5. Assumed the power not only to fix future wages but to render a money award for back wages for services already rendered and paid for without affording the employer an effective right of judicial review.

6. Compelled employers and employees to agree to submit disputes to arbitration contrary to the settled decisions of the Supreme Court.

On this, the report says:

"If one Federal bureau can with impunity destroy the essential legal components of a contract; can without review by the courts render money awards for unlimited sums for past services rendered and already paid for; and can establish the principle that the ability of the employer to pay any wages that the fancy of the Board may dictate is immaterial and not to be considered; it is obvious that such a policy, if unrestrained and exercised by biased agencies not concerned with the judicial elements of a fair trial, may and probably will make serious inroads into our constitutional system of judicial determination and destroy the elementary rights of private property and private enterprise."

THE report makes clear that the assertions of the Board that "they are acting by the direction of the President of the United States and that the President has delegated such authority to them by reason of his war powers under the Constitution are not correct."

Says the report:

"The President does not possess 'war powers' which authorize him to compel an employer whether engaged in war work or not, to release workers who do not maintain their membership in a private labor union.

"The Constitution, Article II, Section 2, provides that the President shall be the Commander in Chief of the Army and Navy of the United States and of the militia of the several states when called into the actual service of the United States.

"The Constitution nowhere confers upon the executive authority such as the War Labor Board purports. The Constitution was not designed to subject to the arbitrary will of civil appointees of the President the liberties guaranteed to all citizens under the Constitution."

Decisions on the war powers of the President by the highest court have been few. The report cites them and it is significant that in none of them

Steel Cost Study Ready This Week

Washington

• • • OPA will have cost information from 90 per cent of the steel industry ready for study by the end of the present week. The information covering carbon steel will first be compiled and studied, followed by a similar study of alloy steel costs. From the report it will be determined whether price increases are necessary. The report also will measure the effect on costs arising from any potential wage increase.

TONNAGE USED 1941 (PART)

TONNAGE USED 1942

1943 TONNAGE

Acceptance Proves Value

HEARTH PATCH is a war-born refractory that has made good.

Open hearth men, driving furnaces for more and more steel to meet war needs, called for an emergency patch material . . . something that could be dumped into large bottom holes to make strong, safe repairs with least delay. Hearth Patch was the answer.

Just how well Hearth Patch serves this purpose is demonstrated by its steadily growing acceptance. Month after month, the tonnage used increases. New customers are trying it, liking it, becoming regular users.

Hearth Patch is designed for quick, emergency repairs. A fine-grained, fast-setting magnesite, it is intended to be thrown quickly, without slag addition, into deep holes while the furnace is still very hot. Properly applied and given a working surface of dolomite clinker, it sets into a dense repair.

Hearth Patch has been much improved in its development over the past three years. It is now a Ramix-type product of high fusibility, greatly increased refractoriness, and remarkable stability.

Our Service Engineers are prepared to assist your personnel in proper ways to use Hearth Patch and other Basic Refractories products—to help you make maximum savings in production time with good refractories.

BASIC REFRACTORIES, INCORPORATED

CLEVELAND, OHIO

has the WLB's assertion been supported.

THE Supreme Court has held that the powers of the President during war are purely military and that his conquests do not enlarge the boundaries of the union nor extend the operation of our institutions and laws beyond the limits before assigned to them by the legislative power. The report points out that the powers granted to Congress with respect to war are more comprehensive than those granted to the President.

Furthermore, the Supreme Court has held that the imposition of the will of a military commander over the will of civilians is called martial law and in any event no great emergency would justify the subordination of the Constitution and its guarantees. Also according to the court, martial law is limited to the theater of actual military operations.

It is significant that the minority report which weakly seeks to rebut these arguments, contains little of sound legal contention, but merely seeks to controvert the law through weasel words.

Chairman William H. Davis adopts the minority report for his answer to the Smith Committee, and asserted on Jan. 26 that the power to "settle disputes" in the War Labor Disputes Act confers the authority to order provisions in contracts to which "parties do not agree."

This answers none of the Smith Committee's objections, but serves to illustrate the determination of the Board to have its way no matter what the settled law may be.

o o o

Army Clarifies Renegotiation Stand

Washington

• • • **Withdrawal** by the War Department of the right of contracting officers to exempt contract termination settlements from renegotiation has encouraged reports that the Department has been acting arbitrarily and inconsistently.

Actually, the War Deparment explained, the revocation of this power presents no departure from prevailing procedures. This exemption clause has fallen into disuse because while contract termination embraces only a few contracts at a time, renegotiation covers a whole year's business.

The general rule of the Department has been to consider canceled contracts as part of the whole of a firm's business when renegotiating. Consequently, since this exemption provision has not been widely employed and because of the differences in the nature of termination and renegotiation, it was decided that discretion to exempt canceled contracts was improperly lodged in contracting officers.

However, the memorandum sets up a clarification of exemptions which may be made with the approval of the director of the Army Service Forces.

The exemptions which apply to fixed price, short term contracts are as follows:

1. Fixed price contracts containing no provision for price adjustment except provisions for equitable adjustment of the price in case of changes in specifications, deliveries, rate of production, or increased expenses resulting from statutory renegotiation.
2. Contracts providing for full performance within six months or less.
3. Where the contractor has had previous experience in producing the same or substantially the similar articles.
4. Where the total cost of performance of the contract can be determined with reasonable certainty at the time the contract is made.
5. Where the contract price contains substantially no allowances or charges for contingencies and any remaining allowances or charges for the particular procurement.
6. Where the profit and the margin of profit are relatively low.

THE BULL OF THE WOODS — BY J. R. WILLIAMS

Committee to Investigate Geneva Mill Sale to Russia

Washington

• • • **Senator McCarran** of Nevada, chairman of the Committee on Centralization of Industry, on Tuesday appointed a subcommittee of three to investigate reports that the Federal Economic Administration has offered to ship the Geneva Steel Co. structural mill and equipment from Geneva, Utah, to Russia. This mill was a part of the steel expansion program and is near completion but recently WPB stopped work on it.

It is reported, however, that Russia does not want to take the project because the power equipment is not suitable for that country's use. The Senators named on the subcommittee are Gillette (D. of Iowa), Murdock (D. of Utah), and Robertson (D. of Wyoming).

Senator McCarran will also meet on Feb. 11 and 12 in Carson City, Nev., with the Attorneys General of California, Utah and Nevada, regarding decentralization of steel capacity and basic magnesium plants in the west that have been built up under the war expansion program and has been or is expected to be partly or entirely abandoned as no longer needed.

HOW DOES THE GAGEMAKER

Check the Gages

HE MAKES ?

Plug gages being checked to a tolerance of a few millionths of an inch at Republic Gage Company, Detroit.

Gages often must be accurate to within infinitesimal tolerance limits—a very few millionths of an inch. These "millionths" must be measured accurately.

The Republic Gage Company and hundreds of other gagemakers know their gages are right because they use Sheffield Visual Gages for final inspection. This widespread use by gagemakers is testimonial proof of dependable, highly accurate performance of the Visual Gage. The responsibility of integrity so imposed is appreciated by Sheffield and respectfully observed by the master craftsmen who *make the instruments by which other types of gages are checked.*

DELIVERY WITHIN TWO WEEKS can be made of your Visual Gage requirements for production and gage inspection. Six amplifications, 500, 1000, 2000, 5000, 10,000 and 20,000 to one. Wire or write for quotation.

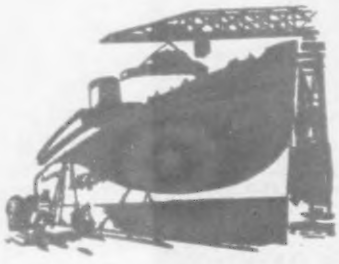
WEST COAST . . . OSGOOD MURDOCK

• From 10 to 20,000 tons of shipyard scrap to be allocated to Midwest mills . . . Another steel-minded Senator proposes tin plate mill for Pacific Northwest.



SAN FRANCISCO — Following several weeks of fairly open discussion and negotiations, alocation orders are being issued to West Coast shipyards for a major movement of shipyard scrap, predominantly plate, to midwestern mills in the Chicago district. It seems likely that from 10,000 to 20,000 tons will be moved within the next 30 days.

In recent weeks West Coast mill buyers have purchased melting grade scrap from $1.00 to $2.00 below ceiling prices, and turnings and borings sell, if at all, much further below ceiling. All mills have inventories for 90 days or more, representing the largest tonnage and value of scrap they have carried for 10 years, since depression days. Since some furnaces and open hearths are shut down, particularly in mills rolling only reinforcing bars and light shapes, and since shipyards continue production, the supply of prime scrap continues to accumulate. Although the mill buyers don't like to see ship plate cuttings and the best scrap ever produced on the West Coast shipped out of the area, they are equally reluctant to accept all allocations at ceiling prices when they can buy commercial scrap for less and when their inventories are already normal to plump. For the next six months, at least, continued scrap production is assured, to supply even maximum demand.

Another important subsidiary was added to U. S. Senate Pacific Steel, Unlimited, last week by Senator Mon C. Wallgren (D. Wash.) when he proposed a tin plate mill in the Pacific Northwest to operate on plate produced at Geneva and available postwar. The Senator points out that "Washington state has the electric power to operate a tin plate mill and installation of facilities there would lift a 400,000 ton burden from transcontinental railroads."

To can Alaska salmon, Walla Walla fresh peas and the varied prewar products of the Pacific Northwest required barely one-third of the approximately 400,000 tons of tin plate sold normally on the West Coast. Columbia Steel Co. has operated a small, old fashioned tin plate mill at Pittsburg, Cal., but it is now shut down. That there should be a tin plate mill somewhere on the Pacific Coast is self evident, and, after the war emergency, it will undoubtedly be a first move by Columbia to replace or modernize its tin plate mill, probably at Pittsburg, since nearly half of all tin plate demand on the Pacific Coast is in central and northern California for fruit, vegetable, and fish products. U. S. Senate Pacific Steel Unlimited must expect competition from existing private plants, and the fact that they will continue to be operated by natural gas or by-product fuel instead of low cost Federal electric power need not thwart their ambition for a share of this well established, long supplied market.

FOLLOWING two big mass meetings of purchasing agents from manufacturers, wholesalers and distributors with representatives from government procurement agencies and major war contractors with surplus materials, held at San Francisco and Los Angeles separately, the WPB Redistribution Division has issued a classified list of materials available. Since the meetings, it is announced that negotiations are pending involving material roughly valued at a quarter million dollars, but discouragingly the publicity in connection with the meetings has developed additional listings from surplus inventories greater in volume and value than what has been moved. On material originally acquired with preference ratings of AA-5 or higher it is necessary to obtain corresponding ratings to dispose of the material, yet the regional WPB offices have authority to waive this requirement in cases where materials are sold to distributors or wholesalers, with the understanding that final sale will observe original priorities ratings. Present materials listed by Region 10, including California, Arizona, Nevada, and southern Idaho, include 22,000 tons of various steel products, mostly in small quantities but involving 500 tons of 3/16x1 in. hot rolled strip, analysis 10/10, in lengths 17 ft. 9½ in., 250 tons of the same material in lengths 12 ft. 8½ in., and 325 tons of 3/16x3⅛ in. strip in 20 ft. lengths. Some 2,000,000 lb. of copper products are listed including, strangely, a cold million pounds of virgin copper 20 lb. ingots. It is generally conceded that this considerable conglomerate mass of material represents only a trickle of what will eventually be available, and that even without priority restriction there would be serious difficulty in moving some of the items listed.

WHEN 23,080 employees of Douglas' Long Beach plant went to the polls in an NLRB election Jan. 26, out of 27,356 eligible to vote, 10,699 voted in favor of the CIO United Automobile Workers of America as their collective bargaining agent. Of 84.2 per cent of employees voting, 46.5 per cent thus favored CIO. For the AFL International Association of Machinists, 4590, or 19.9 per cent voted, while 7725 or 33.6 per cent favored no union. A run-off between CIO and AFL will be conducted within two weeks. This week the 44,000 workers at the Santa Monica plant are voting on the same question.

ALTHOUGH the northern California area officials of the War Manpower Commission and the U. S. Employment Service continue to declare that over 100,000 additional war workers are needed in the area, industrial plants are slightly reducing their personnel and both men and women are filtering from the top brackets back to the service trades and average jobs they held before donning tin helmets and blue overalls for the shipyards. The California Labor Statistics bulletin indicates that there were 4200 less employees in durable goods industries in the San Francisco Bay area in December than in November and a reduction of employment for all manufacturers in the same district from 281,900 to 274,300. Although there is an urgent demand for skilled ship re-

Detachable work unit of new "TOCCO JR. 7½" conveniently mounted on bench in production line.

Announcing another LOW-COST TOCCO

To revolutionize heat treating in thousands of plants

TYPICAL RESULTS

BRAZING carbide tool tips—all sizes. Time: 10 to 50 seconds.

ANNEALING 75 mm. steel cartridge cases to 70-75 R.B. Time: 10 seconds.

HEATING to 2200° F. for forming 1" on end of 1" bars. Output 90 per hour.

HARDENING wearing surface of teeth of small bevel gears. Time: 18 seconds.

The "TOCCO JR. 7½" offers thousands of shops a thrifty head start in the race for *better products at lower cost* with TOCCO Induction Heat Treating.

This new TOCCO has a DETACHABLE WORK UNIT which can be mounted on a suitable bench in the production line (as shown above), handy to related operations, with the power unit located wherever desired. This higher degree of versatility and adaptability of heat treating affords greater production flexibility for fast-moving manufacturers.

Here are the cost-cutting advantages of larger TOCCO machines in a complete motor-generator type induction heat treating unit at a new *low cost*. Output is 7½ K.W. (9600 cycles).

ANNEALING..HEATING

★

pair craftsmen, particularly electricians, the demand for mass labor has slacked off and no one seems to know where the 100,000 which WMC and USES repeatedly request would either live or work or eat.

In 1943 all California factories employed an average of 878,000 wage earners, more than three times the average of 276,300 in 1939. Wages paid these workers last year totalled $2,213,000,000, 50 per cent above 1942 and over six times the amount paid in 1939. For 1943 average weekly earnings were $51.96, average hourly earnings $1.162 and average hours worked per week, 44.7. Part time as well as full time workers are included in the statistics of working time and overtime pay and shift premiums are included in averaging weekly and hourly earnings. These employment figures exclude office, clerical, sales, construction, executive, technical, and professional personnel which, if included, would bring the total employed in California manufacturing establishments last year well over 1,000,000 persons.

AFTER four days on strike, with picket lines in front of 79 foundries and manufacturing plants and unfavorable top headlines in the Seattle, Tacoma, and Portland newspapers, approximately 10,000 foundry workers voted to call off their strike and appeal for a decision following a public hearing before the National War Labor Board.

Labor relations officials throughout the Pacific area observe an increasing restlessness by organized labor and ineffectiveness by labor leaders and officials to hold their members to no strike pledges. There is no personal loyalty nor long-standing acceptance of leadership within the mass production unions that have come into being. Restlessness originates at the bottom, with the men and women in the lower brackets who pay the same dues and who are dissatisfied with their income on a comparative basis, not only as against workers in other industries but even as compared with higher classifications within their own union affiliation.

In recent collective bargaining conferences and negotiations of new contracts, union representatives have been disposed to "stall," very generally expecting a breach of the Little Steel formula and fairly confident that it will not be long before wages are increased 25 per cent over the hold-the-line base, instead of the former 15 per cent.

New West Coast Shipping Council Headed by A. E. Roth

San Francisco

• • • **Election** of Almon E. Roth, president of the San Francisco Employers Council since its organization in 1939, to head the new National Federation of American Shipping is looked upon by business and civic leaders here as a development of prime importance to postwar industry, business and shipping of San Francisco and the Pacific Coast. He has been given indefinite leave of absence from the Employers Council.

Roth knows the West and its agricultural, industrial and shipping problems intimately. He has come to grips with them as president of the Pacific American Shipowners Association, president of the Pacific Coast Waterfront Employers Association, as vice-president and director of the California State Chamber of Commerce, president of the San Francisco Employers Council and more recently a member of the National War Labor Board.

The new organization will work with the government on a program to reconvert the huge wartime shiping fleet to a peacetime basis. Headquarters will be in Washington.

Trade Channels to Handle South African Small Tools

Washington

• • • **The Foreign Economic** Administration and the Union of South Africa Government Supply Mission announced that commercial trade channels will be used for exporting small and hand tools to South Africa for non-military use. Tools for military use will continue through government channels.

Under the new arrangement, South African merchants will submit orders for six months' forward requirements. The orders will be assembled and, from the desired supplier designated on the order, will be grouped together. A summary of all tools from given American suppliers will be prepared and sent with the orders to the United States.

The supplier will use the summary to prepare an application for priority rating for all tools in the CMP product groups. Rating application must show all available information regarding end use and state that tools concerned were included in the 1944 Requirements Program for South Africa. Each supplier must apply to the South African Supply Mission for a release certificate covering each order received from a South African merchant and applications for shipping space, when desired, should be forwarded to the mission.

Fatigue Cracks . . .

BY A. H. DIX

Narrowed Down to Three Centuries

Recently we bragged that while your favorite family journal is able to answer most questions it receives, sometimes it bogs down on seemingly simple questions, as for instance, "When were machine cut nails first made?" Kind friends have given us these answers:

Cut nails were made as early as 1819 over in Wareham, Mass.

—*L. R. Crago, Mgr., Cut Nail Sales Div., Wheeling Steel Corp., Wheeling, W. Va.*

In 1786 Ezekiel Reed of Bridgewater, Mass., patented a machine for making cut nails.

—*F. R. Morral, Industrial Fellow, Mellon Institute of Industrial Research, Pittsburgh*

Although there were patents of earlier date, it is recorded that the first cut nail was made by Jeremiah Wilkinson of Cumberland, R. I., in 1777.

—*E. H. McClelland, Technology Librarian, Carnegie Library of Pittsburgh*

The first cut and machine headed nails were made in England towards the end of the 17th century.

—*H. C. Sproule, Lake Erie Engineering Corp.*

Down to the Last Rivet

Now that that's settled we would like to put into the record the exact answer to another question that gave us grave doubts of the brains department's omniscience—"How many rivets in a battleship?" We told the inquirer the answer was 1,269,983 ("Fatigue Cracks," Dec. 9, 1943). We now have a true count. The Navy reports that the new 45,000-ton USS Missouri" has exactly 1,135,000 rivets. We think it is remarkable how close the brains department came to the right answer, considering that its ouija board is the old-fashioned manually-operated type.

"Where," He Said, "Have I Seen . . ."

Congratulations on the Jan. 20 front cover. We consider ourselves FORTUNE-ate to be represented in this forward moving issue of the D.O.F.J. Again I.A. leads the field in originality.

—*E. C. Shults, Adv. Mgr., Pratt & Whitney, West Hartford, Conn.*

To omniligent Ed Shults an orchid for recognizing the Jan. 20 cover as an identical twin of a former Fortune front cover design. The similarity had escaped us.

Does "D.O.F.J." stand for "distinctly omneitous family journal" or is our first guess correct?

We Stuck Out Our Chin

To keep from getting over-fond of ourselves, every now and then we send a questionnaire to a cross-section of our readers, inviting them to come clean. While we realize that many beautiful friendships have been broken up by the assumption that an invitation to indulge in candor is to be taken seriously, we take a masochistic delight in giving readers an opportunity to plant their Sunday punches on our chin, if so minded.

A chin-unveiling exhibition has just been completed, and we are happy to report that an experimental wiggle of our sub-maxillary reveals it is still intact. The only blow that shook us was a vehement letter from a foreman who thinks we are anti-labor.

This time more than the usual number of readers by-passed our chin completely, reached clear around to our back, and patted it with such comments as these:

"I don't see how you can improve this book. I think it is the best on the market."

"I enjoy IRON AGE *and cannot wish it different in any way."*

"I like your magazine very much. It is the best all around from a technical man's viewpoint."

Others were more temperate, merely telling us that we have "a good magazine," or "better than average." As usual, the feature that garnered the highest number of bouquets was the editorials.

In the line of concrete criticisms, we are told that we should have more on the reader's particular specialty —welding, tool design, farm implements, export markets, and so on. There is, of course, a limit to what the brains department can do in this regard.

A Midwestern manufacturer thinks we ought to put the table of contents page in the same place each week or put the page number on the front cover. As our motto is that the customer is occasionally right, we will investigate.

Another reader suggests, "Make six months index available as a separate pamphlet." We have been getting out semi-yearly editorial indexes since the Democrats tried to win an election with the slogan, "When Mark Hanna whistles, McKinley dances." The index for the second half of '43 is now on the press. Free to all who ask for it.

All in all, we were treated very kindly.

Names That Fit the Job

The president of Stephens Union's student body is Joe Mixer, a pretty example of predestination. Often, however, destiny is thwarted. Herndon A. (Alcoa) Oliver, Jr., calls attention to the case of W. Nelson Bump. Mr. Bump is with our neighbor, American Airlines, five flights up. He should be with a drop hammer concern.

In Defense of J. R. Williams

The left hand twist drill can be easily explained by looking at the sketch in a mirror. This also puts the feed handle on the right side of the drill press where it belongs.

Perhaps somewhere in the process of working up the cartoon for printing a tracing was reversed . . .

—*G. E. Grimshaw, Grimgrip, Inc., New Bedford, Mass.*

But this would also reverse the words in the "balloons" — unless they were lettered in later.

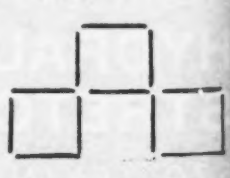
I fly to the defense of J. R. Williams. That is no L. H. twist drill; it's a spiral type reamer, which is correctly left hand to avoid digging in.

—*H. L. ("Red") Blood*

No dice. The helix angle according to your favorite family journal's technical editor, Frank Joseph Oliver, is too acute for a reamer.

Puzzles

As you saw at a glance, last week's match trick is solved as shown in the diagram.



Five minutes is par for this: A man went into four gambling houses in succession. It cost him $100 to get into each one. It cost him the same amount to get out of each. In each house he doubled what he came in with —after paying the admission charge. When he left the fourth house, he had no money left. How much did he have when he started?

"FAIRBANKS-MORSE SCALES—ARBITERS OF BUSINESS"

The Decision Is Final!

Since 1830—Fairbanks-Morse Scales have been rendering split-second decisions recognized as *fair* and *absolute* by buyers and sellers alike.

They are accurate, reliable, honest weighing decisions that have exerted a profound influence on the progress of industries and the welfare of nations.

The accuracy and long life built into Fairbanks-Morse Scales can give you added protection—distinct *plus values* wherever fast—accurate—efficient weighing is essential.

They are tangible *values* developed and pioneered by a company that places no ceiling on whatever it takes to make the finest scales possible to produce.

Fairbanks, Morse & Co., 209 Fairbanks-Morse Building, Chicago 5, Illinois.

Dear Editor:

RESUMED ASSEMBLY LINES

Sir:

About 30 months ago in your "Assembly Line" you described the difficulties of beginning production on new models. We are very anxious to secure about six copies.

P. J. GALETTO,
Sup't of Inspection (Tanks)
Cadillac Motor Car Div.,
General Motors Corp.,
Detroit 32

● See "Assembly Line" for Nov. 7, 1940, page 70.—Ed.

GAS KITCHEN

Sir:

The Jan. 20 Dear Editor page had an inquiry from William Hope of Manchester, England, on modern kitchens. You indicated in your answer that you were turning the inquiry over to the Edison Electric Institute. . . . I would like to point out public acceptance of gas in the home makes it the preferred fuel of millions of people both in the United States and in England. . . . The American gas industry is taking active steps to continue to furnish leadership in the design and development of truly modern American kitchens and homes.

We have written to the gas company in Manchester, England, to furnish Mr. Hope the information he has requested.

C. GEORGE SEGELER,
Engineer of Utilization
American Gas Association,
420 Lexington Ave.,
New York

SUPERFINISH FOR REFLECTORS

Sir:

Your Aug. 19 issue contained a reference to the Superfinish process developed by Chrysler and now being used for plating reflectors. I am interested in getting full information.

WILLIAM M. SIESEL,
Consulting Engineer
Flight Training Research,
Box 589,
Trenton 4, N. J.

● As far as we know, Chrysler is the only concern doing this type of work. The process follows the methods described in the series on Superfinishing in The Iron Age issues of Sept. 1, 8 and 22, 1938. You may be able to obtain specific information on the application of Superfinishing to plating reflectors by writing D. A. Wallace, president, Chrysler Sales Div., Chrysler Corp., 12200 East Jefferson Ave., Detroit 14.—Ed.

COMPARABLE ELECTRODES

Sir:

I believe the table, "Comparable Arc Welding Electrodes," and the booklet, "How to Get Maximum Output from Your Cutting Tools," will be helpful to me. Please send them. A check is enclosed.

MAJOR WILLIAM B. SWEET,
Ord. Dept.
Military Intelligence Service,
Pentagon Building,
Washington 25

MODERN HEAT TREATING

Sir:

Your Jan. 13 article, "Modern Heat Treating Takes a Lot of Know-How," refers to liquid nitriding. What is the name of the manufacturer that supplies the salt? What company has available the Scottsonizing process? Who handles the Nusite hardening process?

W. CORTLYN RHODES, JR.,
Production Mgr.
Air Associates,
Teterboro, N. J.

● Liquid nitriding salt is a product of E. F. Houghton Co., 303 West Lehigh Ave., Philadelphia, and A. F. Holden Co., New Haven, Conn. Nusite hardening was developed by Perfection Tool & Metal Heat Treating Co., 1740 West Hubbard St., Chicago 22. Scottsonizing process is a development of C. U. Scott & Son, Rock Island, Ill.—Ed.

ORDERS IN BLANK

Sir:

Here is a suggestion that may be helpful to some of your readers. When we have occasion to order small quantities of hard-to-locate materials, we make out our regular purchase order in the usual manner, but leave the supplier's name and address blank.

We mail the order to the supplier who we think most likely to have the material attaching the following memo:

"This order carries no supplier's name. If you have the material on hand for immediate shipment, fill in your name, ship and bill material at once.

"In case you cannot fill this order from stock, sign your company name below and forward to whoever you believe might be able to do so. Signing below will avoid having this order show up in your files a second time. Thanks. Just our lazy way of procuring small quantities of hard-to-locate materials."

H. E. PAINE,
Purchasing Agent
Lane Manufacturing Co.,
Montpelier, Vt.

FOREIGN PATENTS

Sir:

Page 114 of your Dec. 23 issue has a list of patents seized by the government and now available to domestic firms. What is the proper procedure in order to obtain copies of patents?

HARRY P. BREWER,
Purchasing Agt.
Milford Rivet & Machine Co.,
Milford, Conn.

● Order direct from the Commissioner of Patents, Washington 25, D. C. Price is 10c each, payable in currency, certified check, money order or Patent Office coupons. No stamps. A 28-page reprint of the seized patent lists published in The Iron Age, up to and including the Jan. 20 issue, is now ready. To get a copy send 24c in stamps to The Iron Age, 100 E. 42nd St., New York 17.—Ed.

TOOL ROOM TIME ESTIMATING

Sir:

I am much interested in time estimating of tool room jobs, but find it impossible to get any literature on the subject. The only information that is published relates to time on production set-ups, or so it seems.

At one time, I discovered an author who stated that there was a method of checking time by allowing so much for different types of cuts, but gave no actual listings. Have you ever come in contact with any books or know of any concern that might be able to help me?

HERMAN SCHWEIZER
9441 109th Ave.,
Ozone Park, N. Y.

● "Time and Motion Study" by Lowry, Maynard and Stegemerten, contains formulas for constructing synthetic time studies on the basic elements of machine operations. The publisher is McGraw-Hill Book Co., 330 West 42nd St., New York, price is $5. Details of time values for various machining operations on dies will also be found in "Die Design and Estimating," published by American Industrial Publishers, 2460 Fairmount Blvd., Cleveland, price $3.—Ed.

HIGH SPEED MILLING

Sir:

We are interested in high speed milling, and are informed that articles on the subject were published in the Oct. 14 and Dec. 9, 1943 issues.

We should like to obtain reprints of these articles.

GEORGE O. SMILEY,
Tool Engineering Department
Saginaw Steering Gear Div.,
General Motors Corp.,
Saginaw, Mich.

Sir:

Will you kindly send me a copy of your five-page report of high speed milling symposium of the last A.S.M.E. annual convention?

D. C. ROWE,
Asst. Works Manager
Bell Aircraft Corp.,
2050 Elmwood Ave.,
Buffalo, N. Y.

MILL PASSES

Sir:

Where can I obtain a treatise on mill passes, particularly in the blooming, billet and merchant mills?

S. E. ELDRIDGE,
Asst. General Manager of Sales
The Newport Rolling Mill Co.,
Newport, Ky.

● The best book we know of is the 1440-page "The Making, Shaping and Treating of Steel," by J. M. Camp and C. B. Francis, published by Carnegie-Illinois Steel Corp., Pittsburgh. We do not know the price.—Ed.

COPPER OUTPUT

Sir:

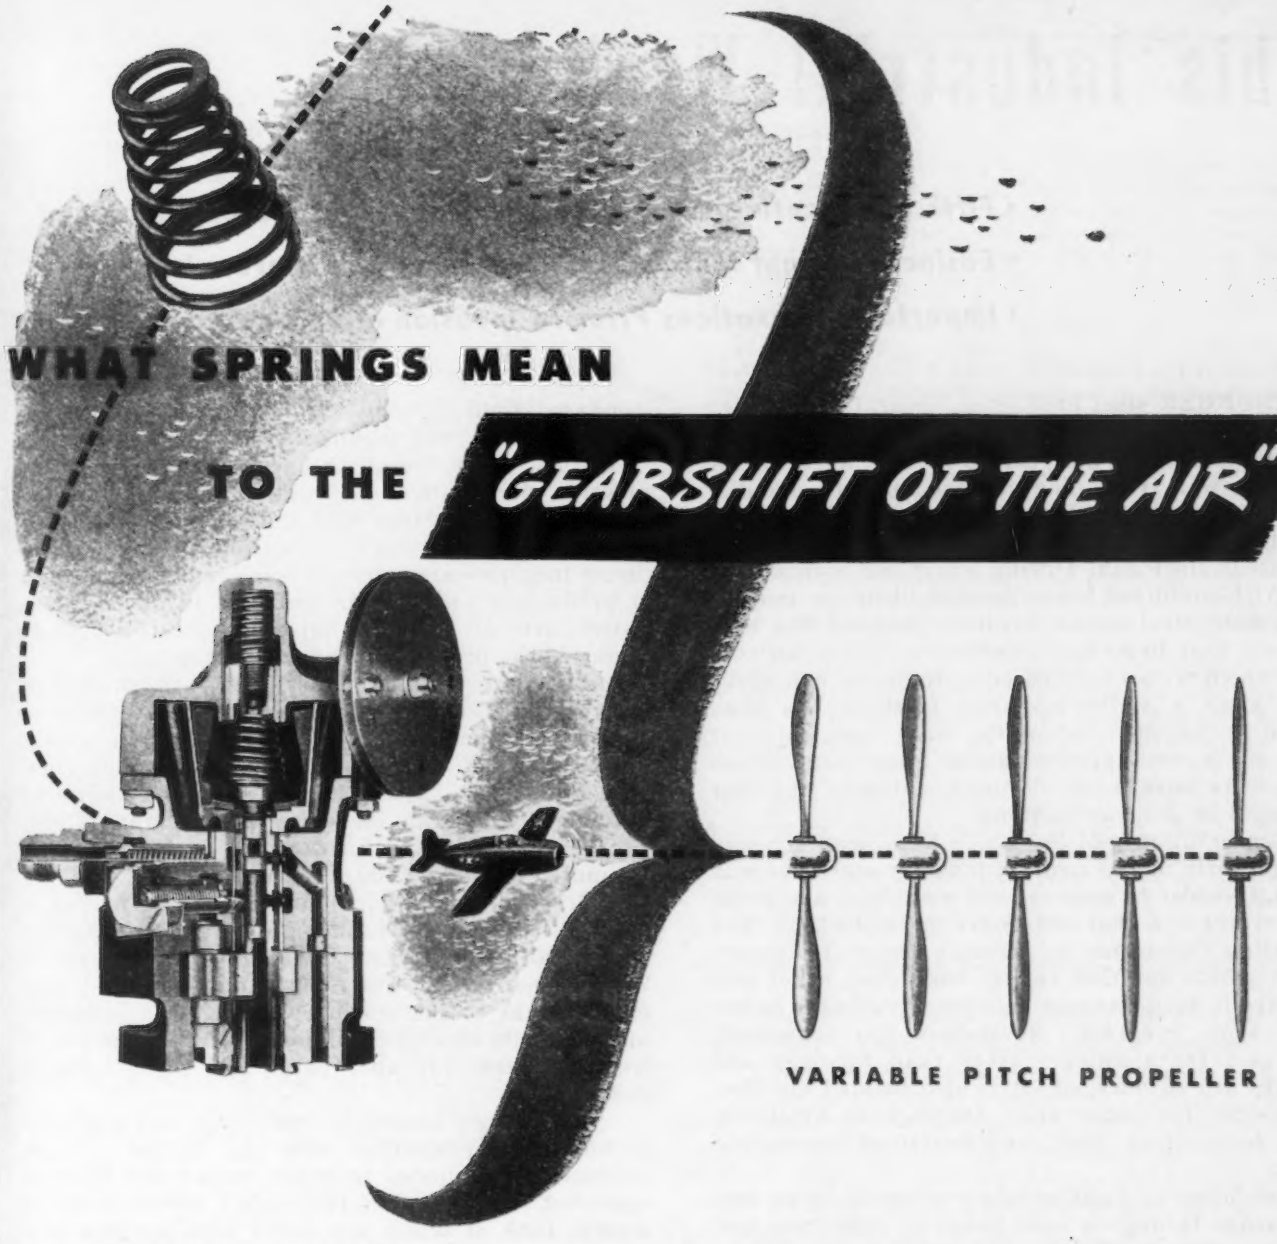
How much copper was made in the United States from 1938 to 1942?

J. A. KNUPP,
Secretary-Treasurer
Waynesboro Manufacturers' Association,
Waynesboro, Pa.

● Refinery production of copper from foreign and domestic ores, in net tons, was:

1938	792,500
1939	1,009,515
1940	1,313,556
1941	1,395,309
1942	1,414,561

—Ed.

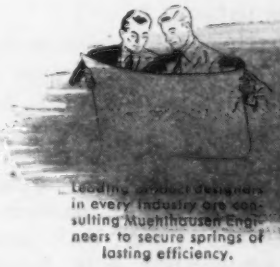


SKYROCKETING—swooping—diving—our planes are driving the enemies dizzy on every front. And one of the main reasons for U. S. air supremacy is the constant-speed propeller—controlled by the Woodward Hydraulic Governor. This maintains a constant engine speed by operating the pitch-changing mechanism of the propeller.

Muehlhausen Springs are responsible, too—for they are important parts of the governor. In the illustration above, note particularly the cone-shaped compression spring located at the top center. The tension of this spring holds the flyballs which, in turn, regulates a pilot valve controlling hydraulic pressure to propeller.

All springs used in this governor are made to tolerances measured in thousandths of an inch, and designed to compress squarely under all degrees of loading. Typical examples of the unvarying precision demanded in the design, fabrication, and testing of Muehlhausen Springs. Send for Die Spring Folder.

MUEHLHAUSEN SPRING CORPORATION
Division of Standard Steel Spring Company
817 Michigan Avenue, Logansport, Indiana



Leading product designers in every industry are consulting Muehlhausen Engineers to secure springs of lasting efficiency.

MUEHLHAUSEN SPRINGS
EVERY TYPE AND SIZE

This Industrial Week . . .

- ***Fifth Consecutive Weekly Rise in Steel Ingot Output Achieved***
- ***Easiness in Light Metals Puts Conservation Program in Reverse***
- ***Important Relaxations Prior to Invasion of Europe Doubted***

STRONGER steel production, typical of the high tempo centering upon the making of invasion equipment, is the feature of this week on the domestic war front. The current jump of one-half point to 99.5 per cent of capacity is the fifth consecutive weekly gain in steel ingot output, the total movement since Jan. 1 being about two points.

With continued heavy demand likely for landing craft, many steel makers are more inclined than ever to doubt that important relaxations in civilian controls which would involve large tonnages can occur until after a well-established foothold has been gained in Europe. But at the same time, in other parts of the metal producing and metal using industries, there have been additional cutbacks and new evidences of postwar thinking.

Conservation policies which have been stressed so vigorously in the aircraft industry since the war began, in order to save critical materials, are going into reverse now that metals are more plentiful. The Operating Committee on Aircraft Materials Conservation points out that copper base alloy sheet and strip are in better supply because of cutbacks in the small arms program. Reversions are suggested. New uses for aluminum other than forgings and castings are encouraged. It is also pointed out that magnesium for other than forgings is available, while ferro-alloys, zinc, and beryllium-copper are easier.

Producers of light metals are urging large tonnage usage through a wide range of industries and some government officials are considering "substantial" programs. Meanwhile, the closing of three more aluminum production lines at Massena, N. Y., was announced this week, bringing the total to 15, equivalent to a 14 per cent decrease in aluminum output.

MARKET trends in steel indicate that the tightest products still are plates, sheets, certain structurals, and pipe. Demand for ingots and semi-finished steel for sale is off considerably from a few months ago. Certain types of bars are in strong demand, but other production units could use more tonnage. Cold finished bar demand has picked up recently due to war requirements. It is reported that WPB may raise the quota on galvanized sheet production, permitting some mills to re-enter the business, and that a large mail order house has applied for permission to stock galvanized sheets. Preliminary inquiries are reported being made on steel for a production program on bathtubs to go to devastated parts of England, but since sheets would be required the program may encounter delay.

Tin plate production during the third quarter, because of recent revisions in M-81, is expected to top second quarter output, which may run around 750,000 tons of tin mill products. It is understood that the sheet situation has been further tightened recently by definite increases in the landing mat program. Previous estimates, before the increase, amounted to about 1,100,000 tons for 1944.

Other highlights include two major moves of the WPB which seem to indicate that the stockpiling of critical materials may be tapered; the cutback of 741 locomotives in the Army's requirements; new evidences as to the adequacy of pig iron supplies; and moderate relaxation of some curbs on the use of iron and steel for auto parts and small tonnage items.

At Chicago, industrial executives are reported to be doubtful whether even the limited civilian production announced in recent weeks will proceed very fast. Producers of two widely varied types of metals, both of whom are faced with surplus production capacity, report that efforts to have these metals released for civilian uses which would require no further fabrication, have been turned down flat.

MAKERS of farm equipment, competing against war goods firms for vital components, are lagging slightly behind their timetable but hope to get back on schedule before the June 30 deadline which customarily marks the end of the farm machinery production year. The industry has been allotted and has placed orders for 974,000 tons of steel covering the periods from last July to next April. For the 1944-45 production season, manufacturers propose that they be permitted to suggest their own production patterns.

Uncertainty over postwar world conditions, particularly exchange rates and wage rates, is said to be a potential barrier to the planning of export sales of steel. Some producers who have studied the problem believe the industry would do well to discount grandiose ideas concerning American steel participation in foreign markets after the war. Before the outbreak of war, U. S. producers were able to export in cooperation with foreign producers on a stated

basis but some encountered periods when their export products sold far below the going domestic market.

In line with the steel industry's drive to obtain higher prices, arrangements have been completed for obtaining cost data for all principal steel products, including alloy steel. A satisfactory tabulation of these data may be expected by the second week in February, according to OPA. Meanwhile, iron ore producers are reported considering a further appeal for price relief during the coming season.

PAYING the full cost of construction, Bethlehem Steel Corp. has acquired from the Defense Plant Corp. some $22,000,000 worth of blast furnaces, coke ovens, and other facilities that were built for DPC in Bethlehem plants. This move may be followed by the acquisitions of scrambled facilities by other steel companies, although not all of them are expected to offer to pay the full cost.

The DPC is reported to have made plans to shut down five of its blast furnaces, indefinitely, as they are completed. Meanwhile, lease agreements for the erection of a charcoal iron blast furnace at Rusk, Texas, have been completed with DPC scheduled to appropriate $2,379,000. This project involves moving an idle furnace from a quarry in Florida.

Sidelights of current markets include the circulation of an aircraft partsmaker's inquiry at New York asking for data on the performance of steel at minus 160 deg. F. West coast steel mill buyers are reported to have purchased "melting grade" scrap at $1 to $2 per ton below ceiling prices recently.

Labor disputes continue to hamper the steel industry. Among several walkouts recently, an unauthorized strike at the Carnegie-Illinois Steel Corp. 100-in. plate mill at Homestead last week, participated in by a crew of eight on the shearing line, caused an estimated loss of war plates amounting to 5000 tons. In Washington, CIO and AFL have stirred up a real fight with the Bureau of Labor Statistics over living costs.

Contributing to the rise in steel ingot output were gains of one point to 101 per cent and three points to 98 per cent at Pittsburgh and Wheeling, respectively. Youngstown operations dropped one point to 96 per cent while at Cleveland output declined two points to 98.5 per cent. Detroit is down half a point to 103 per cent and the Eastern District rate has decreased to 97 per cent from 106.5 last week. Unchanged are Philadelphia at 91; Buffalo at 104.5; Birmingham at 99; Cincinnati at 95; and St. Louis at 101.5.

Tax Bill Renegotiation Sections

Washington

• • • The renegotiation provisions of the new Revenue Act as agreed upon by Senate and House conferees Monday afternoon blasted the hopes of industry that the broader Senate provisions would be incorporated into the bill. Although a few of the minor Senate changes were approved by the conferees, the renegotiation sections of the bill now resemble the more cautious House approved provisions.

As written now, appeal can be made to the Tax Court rather than the Court of Claims as approved by the Senate. A contractor can appeal to the court only in the case of unilateral agreements entered into in fiscal year ending after June 30, 1943. The mandatory exemption of standard commercial articles was also deleted.

However, the secretaries of the various governmental departments have the power to exempt articles in specific cases.

The pricing clauses have been separated from the renegotiation provisions, but the status of repricing is the same. The only change is that it is not an integral part of renegotiation.

The conferees agreed to a Senate amendment terminating renegotiation on Dec. 21, 1944. It may be extended six months or shortened that length of time if the President feels that competitive conditions or fair prices have or have not been established.

The conferees also agreed to the appointment of a member of WPB to the six-man War Contracts Price Adjustment Board as provided for by the Senate. The controversial Senate provision which would have exempted machine tools from renegotiation was rejected by the conferees. The status of subcontracts is the same as under existing law.

THE VICTORY SCRAP BANK DRIVE IS ON NOW

SCRAP piles have taken on a new significance these past few years. Far from being regarded as useless junk, they have become vital national resources. To produce the extra millions of tons of steel needed for war now and in 1944 will require a proportionate amount of scrap. At the outset of the war huge stockpiles were quickly collected from obvious junk scattered plentifully everywhere. Certainly it's more difficult to find this much needed scrap today, unless you are constantly searching for it. So make it a point to clean out your shop (and your home) regularly of all but the absolutely essential metal. Deposit this in the Victory Scrap Bank . . . a deposit that will pay you *real dividends.*

DPC Reported Planning to Close Five of Its Blast Furnaces

Pittsburgh

• • • What final disposition will the government make of DPC blast furnaces and steel plants? Will they be shut down permanently? Will they be sold eventually to those who were selected as agents to run them? Will they be put on the block to the highest bidder? These are a few of the questions in the minds of the steel fraternity.

According to sources here, these are serious queries, because the DPC capacities add up to considerable tonnage. They represent the latest in engineering skill. The location of some of these plants, with respect to normal steel demand and distribution, may be in question, but in most cases the equipment and mills are located in areas already serving large percentages of the nation's steel demand.

Proof that this situation is uppermost in steel officials' minds was expressed recently at Pittsburgh by Benjamin F. Fairless, president, U. S. Steel Corp. of Delaware, who gave his ideas of what should be done. He argued that the government should dispose of its plants and facilities as promptly as possible after the end of the war, and should not compete with private business. In cases where the government plants were more efficient, it should allow private industry to buy or lease these lower cost plants on some equitable basis. Where the plants were uneconomical to operate, they should be scrapped or put under lock and key, Mr. Fairless said. So far, there has been no clear cut policy from governmental circles as to the final disposition of DPC plants.

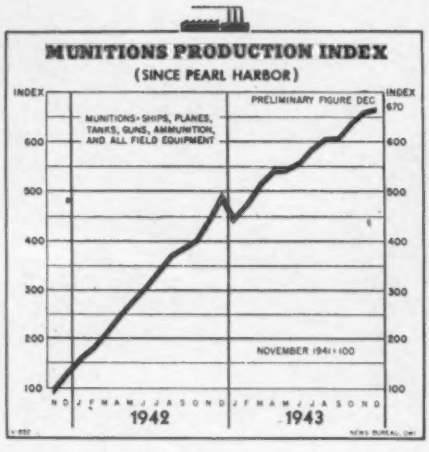
In practically all lease agreements with DPC, the steel company, acting as agent for the government, is said to have the first right to an option on buying the plant. For the present, many of these plants have been ordered shut down, and construction ceased if it has not been completed. However, construction on most blast furnaces and steel plants was well advanced before orders to shut them down were given. It is believed by many that it would be an economical waste not to eventually complete some of these plants.

The problem, for the duration, of those DPC plants, which are now operating, and which probably will not be ordered shut down in the near future at least, is not a serious one. After the war, the situation with respect to those plants will be quite different. Most of the additions now operating are what is known as "scrambled" DPC plants, that is, located in with, or mixed in with, privately owned plants and equipment. There are a few completely integrated, or almost completely integrated, DPC projects, such as the Homestead Works at Pittsburgh, and the Geneva Steel Co. at Utah. The question of whether these units, which are now

• • • Bethlehem Steel Corp., during the past year, acquired from the Defense Plant Corp., all integrated steelmaking facilities in its plants built to the DPC account. These consist mainly of blast furnaces and coke oven batteries that were constructed at the Bethlehem, Lackawanna, Steelton, and Sparrows Point plants, and cost Bethlehem Steel Corp. between $22,000,000 and $23,000,000. This price is stated to be the cost of construction of these units. The acquisition was made, according to E. G. Grace, president, to prevent the government from "being our landlord" on such facilities. This move is believed to be the first in the direction of steel producers obtaining full title to DPC constructed and financed steel mill facilities.

operating, will continue to do so, under the mangement of the company probably depends on two things: the economical cost of running these plants, compared with the cost of running commercially owned plants, and whether or not some of the agents may exercise their option on certain of the units, as the Bethlehem Steel Co. did last month.

Taking as an example the DPC open hearth plant at Carnegie-Illinois Steel Corp.'s Homestead Works: As long as the company is paying a stipulated royalty per ton of steel produced at the DPC plant, to the government, as the latter's agent, the cost of operations plus the rental or royalty would be the figure which would be used to determine if this plant should be shut down, or if some other unit owned by the company should be shut down. In case total demand for steel fell off to such an extent that either the Homestead DPC unit should be shut down or whether one of the company's own plants should be shut down, the decision would be settled by whichever one



cost the least to operate. In the case of the open hearth furnaces or steel rolling mills, this is relatively simple. In the case of blast furnaces, however, a different problem is presented. The increased costs of making pig iron at a DPC blast furnace, due to royalties paid to the government as agent, might present costs higher than production at privately owned blast furnaces, especially in view of the falling off in pig iron demand and the increase in over-all capacity.

The opinion on the disposition of blast furnace units which are not needed, seems to be borne out by the report that the DPC already has made plans to shut down five blast furnaces, indefinitely, as they are completed. It is understood that two of these furnaces already are shut down in the Chicago district for an indefinite period, one at Inland, and one at Republic. There is a definite possibility that the DPC furnace at the Pittsburgh Steel Co.'s Monessen Plant has also been ordered shut down indefinitely. The Daingerfield, Tex., blast furnace is also reported to have been ordered down, and it is further said that one of the three blast furnaces in the Geneva Steel project, will be shut down indefinitely in April when it is completed. These reports seem to indicate the probable trend of action in practically all DPC blast furnaces, in view of the fact that many commercial or privately owned stacks have been blown out recently because of lack of demand.

Farm Equipment Output Lagging; Scramble for Components Is A Factor

Chicago

• • • **Farm equipment** manufacturers are lagging slightly behind their 1943-44 farm production timetable but hope to gather sufficient momentum to meet annual goals for the production year ending June 30.

Competition for automotive components with the landing craft and motor truck programs is causing most of the difficulty. Unfabricated material is in adequate supply with deliveries on time although some worry still is caused by flat rolled steel products. The industry has been allotted and has placed orders for 974,000 tons of steel for the three calendar quarters in the period July 1, 1943, to April 1, 1944, and for the full year will be granted 96 per cent of the steel it used in its biggest previous year.

The December production rate of wheel tractors, the principal motive power item, announced as 20,000 for the month, probably was maintained in January, a preliminary check shows. This figure was the largest for any month in two years and compares with a production of 4200 in December, 1942. Further production speedups will be necessary if the annual goal of 209,000 is to be reached, however. In 1943, wheel tractor production climbed from 15,000 during the first quarter to 18,000 in the second quarter, 33,000 in the third quarter and 56,000 in the fourth quarter. Several manufacturers who had been participating heavily in the tank and certain ordnance programs were enabled to get back into the farm equipment business with all four feet because of cuts in these programs in 1943 and thus have been able to make up lost time.

As in the past, manufacturers who produce most of their own components have been better situated than those purchasing in the open market. Efforts to procure combine engines, a widely purchased item, have run head-on into similar requirements for landing craft, while such automotive items as bearings, bushings, and malleable castings have crossed swords both with landing craft and truck programs. Minor delays have been caused by failure to receive tires on schedule. Some manufacturers, who do not operate their own gray iron foundries report delays in receiving castings caused, assertedly, by commercial foundry labor shortages.

Recognition by the War Production Board of the importance of food production has enabled the farm equipment industry to hold its own as a "must" program even in competition with combat items, it is claimed. George Krieger has moved up from his former post of chief of the WPB Farm Equipment Division to become a special assistant to Donald Nelson with the responsibility of coordinating the food program and equipment requirements. He has been replaced by Charles Deere Wiman, whose business background is with Deere & Co. In order to keep in closer touch with manufacturers, W. F. Heesch, deputy director of the division in charge of production, has established headquarters at Chicago. The division also is setting up regional staffs to expedite the production in various sections of the country, with A. C. Dallach as manager of the important Chicago region.

For the 1944-45 production season starting July 1, it is proposed that manufacturers be permitted to suggest their own production patterns, using the amount of materials allotted them for such machines in such quantities as they wish to build. Lists and quantities of machines proposed as well as their suggested distribution would be submitted to the War Food Administration for approval. It is pointed out that such a scheme might encounter difficulty if manufacturers suggested heavy production of machines requiring large quantities of particularly critical components.

Manufacturers have been given advance allotments of controlled materials for the third and fourth quarters of 1944 to the extent of 100 per cent of allotments for the current period.

•

Ottawa

• • • **Canadian War Expenditures** Committee in a report tabled in the House of Commons said that agricultural implement manufacturers should study the possibility of producing a much higher percentage of Canada's equipment needs. The report continued:

"In view of our tremendous industrial development brought about by the war, and in view of the dominant position which Canadian agriculture now holds with respect to food production, it is unthinkable that Canadian manufacturers should continue to supply only 38 per cent of the farm implements used in this country. . . ."

WPB Announces Program for Stockpiling Critical Materials

Washington

• • • **The first statement** of stockpiling policy adopted by the government was drawn up at a meeting of the WPB on Jan. 25. The Board agreed to put into operation the following program:

1—Maintenance of Critical Material List with periodic reviews by the Program vice-chairman.

2—The following criteria were adopted to govern the size of the stockpiles of various metals: (a) possibility of losing territory; (b) interruption of imports by submarine warfare or other enemy action; (c) land transportation tied up; (d) disruption of production through accident, sabotage, or strikes; (e) where shortages develop, metals supply would be increased to fit requirements.

3—Where the foregoing standards do not provide a guide, then the government will fix stockpiles at one or two stocklevels—either at three months' total requirements, or at one years' requirements. To arrive at this figure, domestic production is subtracted from estimated future imports.

Meanwhile, executive vice-chairman

Here is Up-to-date List of WPB

• • • **Many report forms** of WPB Steel Division have been discontinued, according to a recent memorandum prepared by W. A. Hauck, chief of the control branch. Other reports have been abbreviated. There are still 36 Steel Division forms on which reporting is required from steel producers. Twelve reports are on the subject of ferro-alloys, and five are in connection with warehouses. The three basic reports, WPB-180, WPB-2848 and WPB-2633, are substantially reducing the need for special branch reports.

Report Forms Now in Use

1. Control Branch: (Basic Reports)

- WPB-180 Ingot Capacity and Production Report
- WPB-2633 Report of Shipments and Past Due Orders
- WPB-2848 Production Directive Report

2. Alloy Steel Branch

- WPB-949 High Speed and Tool Steel Production
- WPB-2933 Alloy Steel: Melt Report

3. Carbon Bar & Semi-Fin. Branch: (None)

4. Cold Finished Bar Branch

- WPB-1727 C.D. Carbon Shell Steel: Requirements

5. Export Steel Branch: (None)

6. Ferro-Alloys Branch

- WPB-689 Chromium: Stocks, Consumption, Allocation
- WPB-765 Molybdenum: Application, Allocation
- WPB-1770 Ferro-Alloys: Permission to Use
- WPB-2362 Columbium: Stocks, Consumption & Allocation
- WPB-2446 Molybdenum: Prod. & Consmpt. of Wire, Rod & Sheet
- WPB-2868 Tungsten: Application for Allocation
- WPB-2870 Tungsten: Consmpt. & Allocation of Wire & Rod
- WPB-2871 Nickel: Stocks, Consumption & Allocation
- WPB-2872 Nickel Chemicals: Deliveries & Allocation
- WPB-3452 Cobalt—(Letter from Producer on Shipments)
- WPB-3453 Molybdenum—(Letter from Producer on Shipments)
- WPB-3454 Vanadium—(Letter from Producer on Shipments)

7. Forgings & Castings Branch

- WPB-970 Steel Forgings: Shipments and Unfilled Orders
- WPB-971 Iron Castings: Capacity and Production
- WPB-2681 Steel Castings: Shipments, Past Due Orders

8. Metallurgical & Conservation Branch: (None)

9. Pipe Branch: (None)

10. Facilities Branch

- WPB-3196 Application for Extraordinary Repairs

11. Plates & Shapes Branch

- WPB-652 Steel Plate Order Report
- WPB-653 Summary of Steel Plate Order Reports
- WPB-1566 Telegraphic Report of Plate Shipments
- WPB-1583 Structural Shapes—Weekly Rolling Schedule

12. Rail & Track Accessories Branch: (None)

13. Raw Materials Branch

- WPB-2903 Scrap: Producer's Report
- WPB-2904 Scrap: Consumer's Report
- WPB-2905 Scrap: Dealer's Report
- WPB-3174 Pig Iron: Producer's Report

14. Sheet & Strip Branch: (None)

15. Tin Plate Branch

- WPB-3329 Tin Plate: Letter on Stocks for Cussomers

16. Tubing Branch: (None)

17. Warehouse Branch

- WPB-1722 Steel Warehouse Earmarked Stock

Charles E. Wilson ordered all material divisions to advise the Combined Raw Materials Board when taking any action affecting domestic production, imports, conservation, or stockpiles. The new policy makes WPB take into account "the international implications of their recommendations."

Mr. Wilson's order says that the need of advising CRMB is "particularly important when a major change in policy is being contemplated or when the United Kingdom or other countries have cooperated with the United States in building up the present position in the commodity in question."

Such new programs are to be "discussed informally" with CRMB members. Mr. Wilson said that the purpose of these communications will be to advise other nations of plans before they are put into effect and thus to assure that the necessary cooperation in the international raw materials field can be discontinued."

The materials affected are: Ferro-alloys, iron ore, cadmium, copper, graphite, lead, magnesium, chromite, cobalt, manganese, mercury, mica, molybdenum, silver, tantalite, tin, tungsten, vanadium and zinc.

This action by WPB is significant in view of speeches made by WPB vice-chairman W. L. Batt advocating that postwar foreign trade and international debts be paid in raw materials from abroad. Mr. Batt has also suggested the stockpiling of such critical materials as could not be immediately absorbed into the economy.

Steel Division Report Forms and Discontinued Reports

Chicago Executives Doubt Whether Even Limited Civilian Output Will Proceed Fast

Chicago

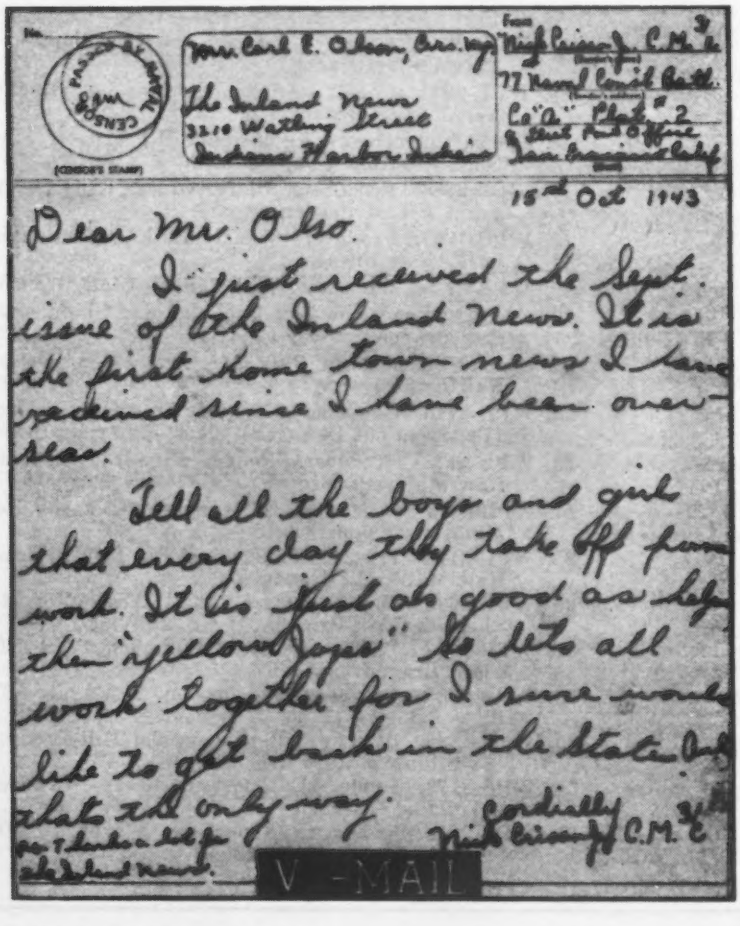
• • • **Despite** persistent reports that WPB will revise limitation orders and allot materials to permit production of civilian items on a limited scale, local manufacturers and metal producers declare that approval of any such program, no matter how small, still is being withheld in stratospheric government circles.

Producers of two widely varied types of metals, both of whom are faced with surplus production capacity, report that efforts to have these metals released for civilian uses which would require no further fabrication have been turned down flat. Until invasion of the European continent has been successfully achieved, the metal producers were told, no metal will be released for civilian purposes. This decision apparently has been battled up from War Production Board divisional levels, through Donald Nelson, who has been reported sympathetic, through James F. Byrnes, who has been critical, and beyond, where Army-Navy opposition to date has won out. Even though mines, smelters and mills may curtail production and operating and managerial staffs disintegrate, the decision has been represented as final.

In fact, the so-called "test tube" program in which small concerns in three limited areas would be allowed to use idle materials in production of consumer goods may yet be in jeopardy although the fact that it was planned was announced officially by WPB chief Donald Nelson before the conference of Mayors at Chicago, Jan. 21. The following day, it is reported, the same high official level which has vetoed previous civilian programs acceptable to WPB repeated in unequivocal terms its no-production-whatsoever ukase.

The revision of WPB Order L-63 to permit manufacture of electric irons on a small scale is so long overdue that it is openly feared here that the revision may have been completely stalled, even though WPB and manufacturers had agreed, and announced, their exact plans concerning distribution of production quotas. The electric iron case, in fact, is said to have become the cause célebre of all civilian goods manufacture, even to the pricing method fought out over Byrnes' desk. Despite WPB insistence that the iron order still is to be issued, rumor has it that this tiny flame of civilian indulgence has been stamped out for fear that it might become incendiary to an uncontrollable blaze. At any rate, local electric iron manufacturers scheduled to share in the program say they have had no hint whether or when schedules would be released and materials alloted.

KEEP MILLS GOING: *This V-mail letter, received by "The Inland News," Inland Steel Co.'s employee publication, from Nick Crisso, a former employee now with Seabees in the South Pacific, tells its own story. He appeals to the "boys" in the mill to keep 'em rolling so he can come home.*



15th Oct 1943

Dear Mr. Olso.

I just received the Sept. issue of the Inland News. It is the first home town news I have received since I have been over-seas.

Tell all the boys and girls that every day they take off from work. It is just as good as help them "yellow Japs" So lets all work together for I sure would like to get back in the States only that the only way.

Cordially
Nick Crisso C.M.3/c

Brazilian Tantalite Mining Urged by U. S. Government

Parklhas, Brazil

• • • **By agreement** with the Brazilian Government, the U. S. Purchasing Commission, now a part of Leo Crowley's Foreign Economic Administration, buys all of Brazil's tantalite output and loans money to private producers to stimulate development of the mines. Although 1943 tantalite production zoomed 140 per cent over 1942, actual production figures are small.

Mining the ore deep in the Brazilian interior has been no easy job for American engineers and Brazilian technicians, but the worth of this rare mineral in the Allied war effort is great. Tantalum, the metal which is derived, is what makes the ore so worthwhile. Exact military uses are secret, but tantalite's importance can be realized from its high air priority —A-1-A. The pure ore is flown to the United States and processed.

In order to counteract mine owners' belief that the tantalite business is a war bubble that will soon burst, USPC men have eased their burden through loans and higher prices, and by pointing out the great peacetime future which tantalite appears to have in the field of electronics. U. S. government agencies are sending down about $250,000 worth of mining equipment for the project.

Army Cuts Its Locomotive Orders

• • • **Manufacturers** of large and small steam locomotives have been advised that altered military requirements will reduce by 741 the number of steam locomotives of 80 tons or more, and by 162 the number weighing from 50 to 80 tons, from the scheduled quotas for 1944, the War Production Board announced Jan. 28.

Within the past week industry representatives from both groups of manufacturers have met in Washington with Government officials to evaluate the effects of these reductions, which will amount to approximately 25 per cent of the military orders for the large type and 35 per cent for the small.

WPB officials said the reduced requirements would not release any existing production facilities, since the original program called for progressively increased production in each quarter of 1944. Plans of the industry now call for an evening out of operations. Military requirements remaining to be supplied in 1944 call for more than 2,000 large and 300 small steam locomotives.

In addition to these still heavy military requirements, approximately 275 steam locomotives of various sizes for domestic use have been scheduled for delivery during the first nine months of this year, according to officials of the Transportation Equipment Division of WPB.

•

Toronto

• • • **Canadian** National Railways has placed the following rolling stock orders: with Canadian Car & Foundry Co., Ltd., Montreal, 2,300 box cars and 200 flat cars; National Steel Car Corporation, Ltd., Hamilton, 2,050 box cars; Eastern Steel Car Co., New Glasgow, Nova Scotia, 700 box cars and 500 70-ton copper cars; Canadian National Transcona Shops, Winnipeg, 200 refrigerator cars, and with Montreal Locomotive Company, Montreal, 20 mountain-type locomotives. 1500 cars and 28 locomotives on order; Bessemer and Lake Erie reports six heavy locomotives to be delivered and C. & O. reported part of an order for 3000 composite coal cars delivered, with several locomotives on order. Grand Trunk & Western let contracts for 300 gondolas, 200 automobile cars and 10 diesel electric locomotives. Lehigh Valley reported partial delivery of 250 gondolas and an order for 900 hopper cars. New York Central let contracts for 1000 box cars and about 70 locomotives; Nickel Plate has on order 500 box cars, 500 hopper cars, 50 gondolas and 30 freight engines; Pennsylvania R. R. has had partial delivery on 116 steam locomotives, 6 diesel-electric, and 10 electric locomotives, 1000 gondolas and 94 flat cars.

Barge and Cargo Ship Contracts Let

Washington

• • • **The contract for** construction of three more C-3-S-A3 (export type) cargo vessels has been awarded to Bethlehem-Sparrows Point Shipyard, Inc., Baltimore, the Maritime Commission announced last Friday. The new vessel, scheduled for delivery in the spring of 1945, are of the same design as four others being delivered in May, June, October and November of 1944.

The ships are of the type of the Commission's long-range building program which began in 1937. The C-3 type cargo ships have a capacity of 9902 deadweight tons and steam turbine engines which develop 8500 h.p. Normal speed is more than 16 knots.

Allocations of 50 1250-ton, all steel, dry-cargo barges to 10 inland waterway transportation companies were announced Jan. 20 by ODT.

The companies and the number of barges allocated to each are as follows: American Barge Line, Pittsburgh, (4); Commercial Barge Line, Inc., Evansville, Ind., (3); Arrow Transportation Co., Paducah, Ky., (4); Mississippi Valley Barge Line, St. Louis, (10); Central Barge Co., Chicago, (6); Marine Transit Co., Chicago, (2); Ohio River Co., Cincinnati, (5); Federal Barge Lines, St. Louis, (10); Mechling Barge Line, Joliet, Ill., (4); and George N. Childs, St. Louis, (2).

Two new 141,000-barrel (T2-SE-A1) tankers, scheduled to be completed by the middle of February, will join the fleet of The Texas Co., the Maritime Commission announced. They are being built at the Sun Shipbuilding and Dry Dock Co., Chester, Pa.. The Commission said The Texas Co. was buying the new tankers at war-time construction costs, less the cost of national defense features, and was asking for no construction or operating subsidy.

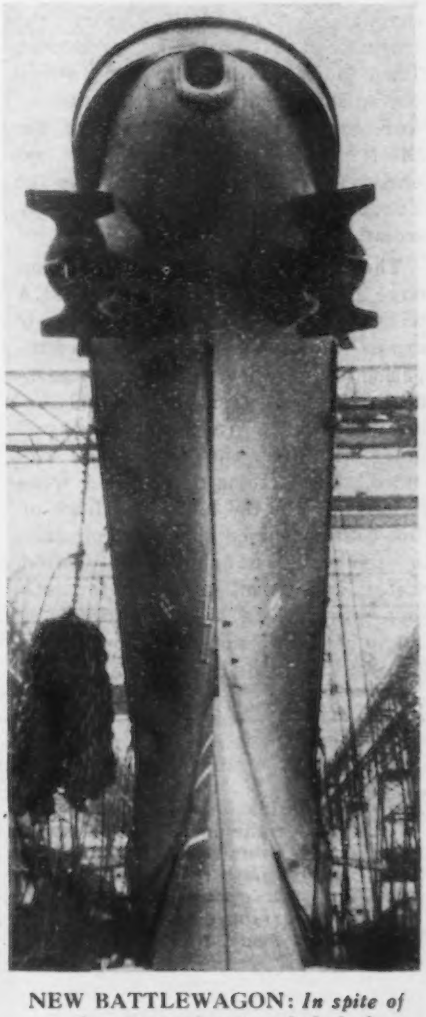
Railroads Let Contracts for Rolling Stock for 1944 Delivery

Cleveland

• • • **Coming aid for** the railroad rolling stock situation here is reflected in the call for bids by the Chesapeake & Ohio Railroad for 5000 hopper type coal cars and 15 Mallet freight locomotives. The Erie Railroad reports that the need for cars may bring forth a call for bids sometime in February.

Contrasted with this are the railroad reports gathered by the Great Lakes Regional Advisory Board which indicate that approximately 2.37 per cent of owned and leased rolling stock of several of the major haulers is listed as bad order.

The Baltimore & Ohio reported



NEW BATTLEWAGON: *In spite of early notions that aircraft had obsoleted surface craft, need for bigger and better ships is now more apparent than ever. The 45,000-ton "Missouri," launched Jan. 29 at Brooklyn Navy Yard nine months ahead of schedule is described by the Navy as the "world's mightiest battleship."*

Uncertain World Conditions To Be Barrier for Export Planning

Pittsburgh

• • • Sir Andrew Rae Duncan, British minister of supply, who has been in this country, toured plants of Carnegie-Illinois Steel Corp. and Jones & Laughlin Steel Corp. here this week. The visit of Sir Andrew, former chairman of the British Iron and Steel Federation, aroused discussion here as in other cities, concerning probable world postwar steel distribution problems.

Steel leaders here recall that before the war, and under the aegis of the Webb-Pomerene Act, American steel producers were able, within the framework of the anti-trust laws, to participate and apportion export steel tonnage, as mutually agreed by United States and foreign producers. The American organization, which was disbanded last year because of war conditions, was known as the Steel Export Association. For several years, William S. Todd was the European representative of the association.

The distribution of export steel tonnage among the members of the SEA was carried out on the basis of their export sales in a certain previous base period. It is believed by some experts that British steel interests would certainly favor a re-establishment of this set-up after the present war has ended. The actions of the SEA were strictly within the anti-trust laws of this country, since they applied only to steel sold outside of the United States, and permission to enter into such agreements was contained in amendments to the anti-trust laws. Restraint of trade, either domestic or foreign, against non-members of SEA was prohibited.

The possibility of a recreation of an American steel export association is not necessarily a foregone conclusion, according to some steel leaders here. Until a more certain forecast of postwar conditions, such as exchange rates, labor rates, etc., can be made, it is hardly likely that steel producers of the United States can, or will, be able to make any commitments. One major impasse, which would have to be settled, probably involves the vast difference between average wage rates paid in this country and those paid abroad. Exchange rates and the cost of steel making in this country will be of far greater importance than other factors, according to steel observers here. While exact labor rates paid abroad are not available at this time, it is significant that in 1936 the average American rate was about 66 cents an hour, whereas in recent months it has climbed to in excess of $1.13 an hour. While some of this increase is due to overtime and incentive payments, nevertheless the bulk of the increase in steel labor costs is due to substantial increases over the past several years in base labor rates. This condition, plus other factors, according to some steel officials, present a sobering thought to those in the industry who look for an unprecedented export steel business. There are some steel producers who have studied the problem, who believe that the industry would do well to discount grandiose ideas concerning American steel participation in foreign markets after the war.

Some American steel companies would, also, prefer to forget some of their experiences with export business during 1936 and in 1938, when American products were shipped abroad at as much as $10 a ton below the going domestic prices. According to some observers here, the problem of sharing in the world export market, outside of the United States, will be important but not too much of an immediate postwar concern, owing to the exceptionally heavy demand which is anticipated on the home front, after the war is over. Obviously, when steel operations begin to slump sharply in this country, there will be considerable interest in foreign markets. However, in view of the wide divergence between labor costs abroad and those at home, as well as exchange problems, some sources believe a government subsidy would be necessary if American steel received wide distribution abroad. It is understood here, however, that American steel officials have an open mind on the question, and realize as much as any other country the necessity for world-wide cooperation in the manufacture and distribution of steel abroad.

Steel exports from the United States, prior to 1937, averaged between 4 and 5 per cent of the total steel produced for sale in this country. In 1937 there was a sharp rise in the percentage, due apparently, to pre-war influence. Figures for war years are not available. Participation of American steelmakers in export business, given in percentages of total steel produced for sale, since 1930 to 1939, follows: 1930, 4.8 per cent; 1931, 4.4 per cent; 1932, 3.7 per cent; 1933, 4.0 per cent; 1934, 5.7 per cent; 1935, 4.4 per cent; 1936, 4.1 per cent; 1937, 7.4 per cent; 1938, 7.5 per cent, and 1939, 7.5 per cent.

Grace Takes 58.8% Slash in Salary

• • • The salary of E. G. Grace, president of Bethlehem Steel Corp., was cut 58.8 per cent from $537,724 in 1942 to $221,645, which totals $42,546 after Federal income taxes. He and other executive officers at Bethlehem have again volunteered reductions in 1944 that will limit their incentive compensation to the amount paid in 1943. After all Federal income tax requirements in 1944 are met, including the 12.5 per cent holdover tax, Mr. Grace's salary will amount to $20,159.

1943 Steel Earnings

• • • Examinations of early reports of profits for the last quarter of 1943 and for the entire year show no indications of a trend toward either higher or lower net profits. Some companies show earnings for 1942 were higher than for last year but as many indicate lower profits during the past year. This tabulation is only for companies that have thus far reported earning and will be supplemented by more complete data in a subsequent issue.

COMPANY	EARNINGS DURING		
	4th Quarter	Year, 1943	Year, 1942
U. S. Steel Corp.	$13,389,673	$63,642,322	$71,248,569
Bethlehem Steel Corp.	12,707,797	32,124,592	25,387,760
Inland Steel Co.	.....	10,810,574	10,721,372
Jones Laughlin Steel Corp.	2,451,647	9,512,228	10,141,690
Youngstown Sheet & Tube Co.	.....	8,037,442	10,305,706
Keystone Steel & Wire Co.	490,568	726,720*	456,931*

* Six months earnings as fiscal year starts July 1.

Consultation with Advisory Groups Is Promised by WPB

Washington

• • • **Codified** into a single order, GAO 2-141, signed by chairman Donald M. Nelson, WPB on Monday restated a policy outlining the rules and orders applicable to all group meetings of industry representatives and Industry Advisory Committees with WPB officials.

Under the new order, which makes no changes in policy or procedure, no limitation, conservation order or amendment may be issued without prior consultation with an advisory committee if the changes will result in a substantial alteration in the operation of that industry. A WPB vice chairman, however, is authorized to waive this requirement only in case the order is of an unusually confidential character or if the necessity for speed of issuance makes such waiver expedient.

Among features of the new order are:

The section on objections to proposed orders states that "the Office of Industry Advisory Committees shall be responsible for notifying all members of existing committees, or committees which shall be created in the future, that any committee member may write a memorandum of objection to a proposed order to the vice-chairman responsible for the industry division involved, except for those advisory committees within the Office of War Utilities and the Office of the Executive Vice-Chairman, in which cases the objections may be sent to the director of the Office of War Utilities and the Executive Vice-Chairman, respectively. These officers may, in their discretion, instruct the Government presiding officer to call additional meetings of the committee to permit further consideration before final action is taken."

The section on meetings called by industry states that "no representative of WPB shall attend any meeting called by a trade association or any other industry organization or group of industry representatives unless the meeting is a sizable one to which all members of the trade in the vicinity are invited or would be admitted or unless the meeting is public in character. Speeches or remarks made at such meetings by representatives of WPB shall be designated by the persons making them as wholly unofficial. No representatives of WPB shall attend any informal meeting of limited attendance called by industry representatives. Any discussion of WPB business by representatives of WPB and representatives of industry at meetings called by representatives of industry is contrary to the provisions of this order and outside the protection afforded by the agreements made between the Attorney General of the United States and the General Counsel of WPB relating to the anti-trust laws."

Armco Strengthens Control of Rustless by Stock Purchase

• • • **The American** Rolling Mill Co. announced that it had agreed to purchase from C. E. Tuttle, president of the Rustless Iron and Steel Corp., all his common stock interest in the latter company. It was indicated that Mr. Tuttle would retire soon as president and a director of Rustless but that arrangements were being made through which he would render thereafter advisory service to Armco and its subsidiaries.

For a number of years Armco has owned a controlling interest in Rustless. It is expected that Charles R. Hook, president of Armco, will succeed Mr. Tuttle. For the past nine years Mr. Hook has been a director of Rustless.

SCALE MODEL: *Admiral Vickery admires scale model of an escort carrier of which delivery was accepted on 19 during 1943.*

U. S. Steel's Capacity Set at 33,675,000 Tons

• • • U. S. Steel Corp. estimates its ingot capacity now at 33,675,000 tons, according to Irving S. Olds, chairman. This figure includes ingot capacity scheduled to come into operation over the next six months. It includes capacity which the corporation is operating for the government. On July 1, 1943, the corporation set its capacity at 31,330,700 net tons. The new figure includes two-thirds or 867,000 of the Geneva project capacity, and 1,740,000 tons at Homestead. Deductions include the 242,000 tons at the abandoned Pencoyd plant and minor adjustments totaling some 20,000 tons.

U. S. Steel's Sales Rose But Profits Dipped in '43

• • • **Earnings statements** of United States Steel Corp. for the past two years compare as follows, with 1942 items adjusted to give effect to contract renegotiations:

	1943	1942
Sales and rev.....	$1,979,081,554	$1,862,951,692

Whiteside Resigns WPB Post

Washington

• • • **Arthur D. Whiteside,** WPB Civilian Requirements vice-chairman, has resigned effective Feb. 19 to return to his post as president of Dunn and Bradstreet. Mr. Whiteside stated his decision to leave WPB was in no way caused by the fact that the armed services have laid down the law that no general civilian production can be started until the outcome of the invasion is known.

Although reports that WPB chairman Donald M. Nelson is considering the names of three men to fill Mr. Whiteside's job have been published, OCR officials say that Mr. Nelson has tried unsuccessfully for more than 60 days to get someone from industry to fill the assignment.

Union Steel Wage Fight Draws Rebukes to Government Statistics

Washington

• • • **In setting the** stage for enforcing demands for a steel wage increase, designed to be a forerunner to general wage increases throughout the ranks of labor, CIO and AFL have stirred up a kilkenny cat fight with the National War Labor Board and the Department of Labor's Bureau of Labor Statistics.

Turning to the technique of beating the other side to the draw, the unions pulled fast tricks that have roughed up both WLB and BLS. His eye immediately on the demand of his USWA for a steel wage boost, Phil Murray, speaking as the CIO head, told the Senate Committee on Education and Labor last week that steel workers' living costs had increased 50 per cent since January, 1941, the date on which the Little Steel formula is based.

Whereupon he was sharply challenged by acting commissioner of labor statistics A. F. Hinrichs. The commissioner, while conceding that the Bureau's figure of a 23.5 per cent rise in the cost of living might be subject to questioning, took sharp issue with Murray's much more altitudinous figure which was declared to be a "very daring" one for anyone to present as typical. Mr. Hinrichs, irritated at the attack on the Bureau's figure as unreliable, is scheduled to make a detailed reply to Murray's statement, which was an extemporaneous presentation and is widely accepted as full of errors. Mr. Hinrichs, nevertheless, told the Committee that the CIO steelworkers' "study" "ably demonstrates that even at a wage level of $50 a week families have to live very narrowly and with no access to luxury goods."

But not content with arousing the ire of BLS alone, two labor members of the Presidential Committee on the Cost of living issued publicly a "recommended report" before the public member, WLB chairman William H. Davis and the two industry members, George K. Batt of Newark, N. J., and H. B. Horton of Chicago, had studied the report. The report does not square with Murray's statement. It said that the cost of living had increased 43.5 per cent since Jan. 1, 1941. While much higher than shown by BLS it is 6.5 per cent under the Murray calculation.

This report, covering the cost of living and the BLS index, made by R. J. Thomas of CIO and George Meany of AFL, drew replies from both Mr. Davis and Mr. Hinrichs. Mr. Davis said that the report was submitted to the Committee on Jan. 25 but that, "it is not in any sense a report of the Committee." Mr. Davis said that industry members will submit their comment in "due course." A copy of the report was also given to the BLS for comment. These comments, and all other relavent data will, of course, Mr. Davis said, be carefully considered before the Committee makes its report to the President.

Meanwhile, however, Mr. Hinrichs issued a statement challenging the CIO-AFL report just as he criticised the Murray statement. Mr. Hinrichs said that, in compliance with Mr. Davis' request, the Bureau would study the CIO-AFL document carefully and submit comments and criticisms. Mr. Hinrichs did, however, take occasion to make passing comment on the report. Discussing that part of the report which placed the food price rise at 75 per cent since January, 1941, Mr. Hinrichs said that the BLS index shows that the January, 1941 $10 basketful would now cost $14.

"The Thomas-Meany report says $17.40," Mr. Hinrichs pointed out. "Every retailer knows that food prices have not gone up twice as fast since price control as before and no housewife would claim it."

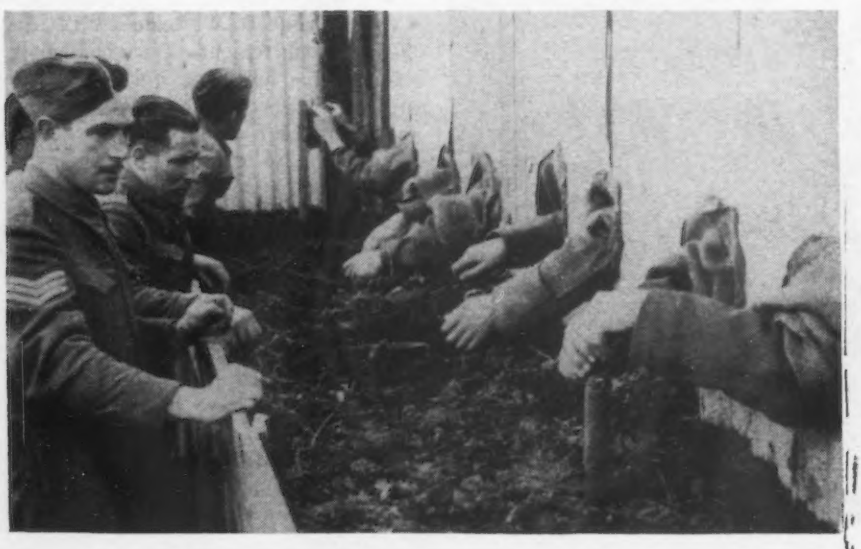
All of these discussions and differences over the rise in the cost of living are a setting for the steel wage case, which in turn is being used as the framework for a general wage increase in industries where no recent increases have been granted. Whether the CIO-USWA will succeed in cracking the Little Steel formula is therefore a question of great importance, not only as it affects the steel workers and steel costs, but as it affects industry and inflation generally.

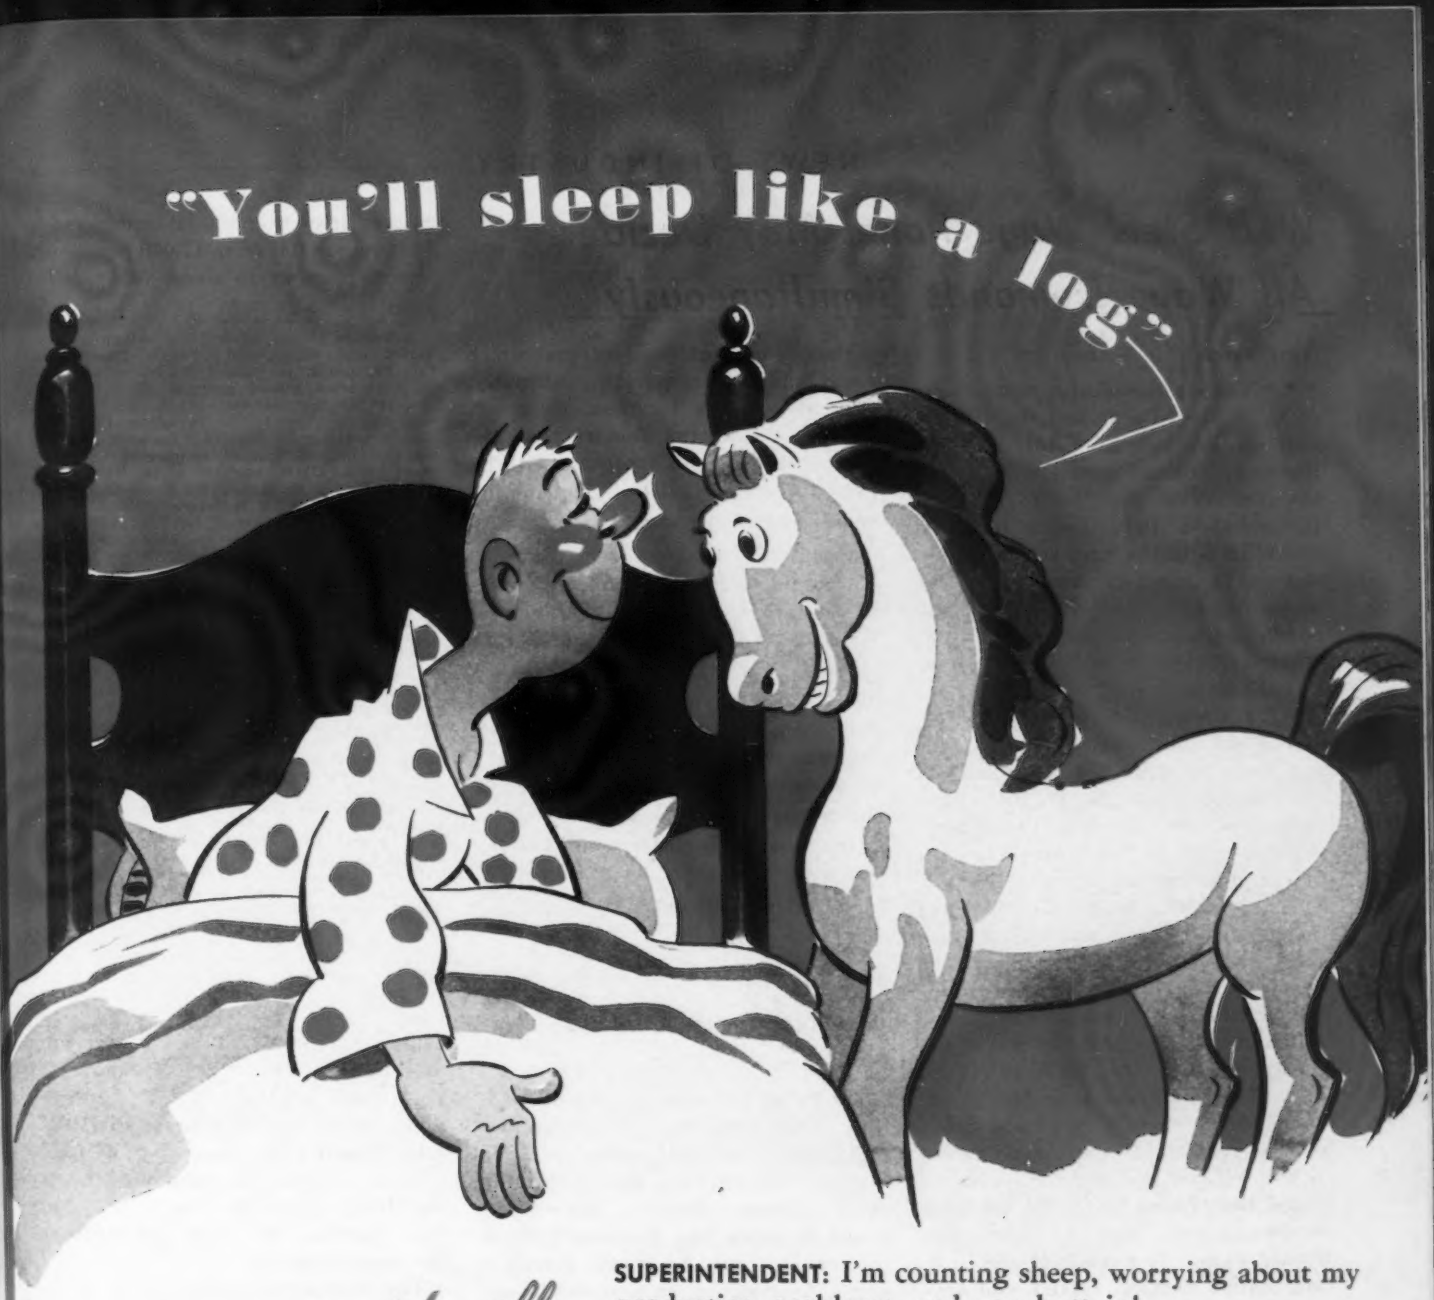
Because of its past habit of yielding to labor demands, often at the White House direction, the common opinion is that the steel workers will be given a further wage increase, though not the full 17c. an hour increase that they are asking.

One of the many speculations is that the WLB will grant an increase covering the difference in the cost of living of today as compared with the Jan. 1, 1941, cost. On the other hand there is a report that Fred Vinson, Director of Economic Stabilization, has told WLB that it is his opinion that the steel workers are not entitled to a further wage increase.

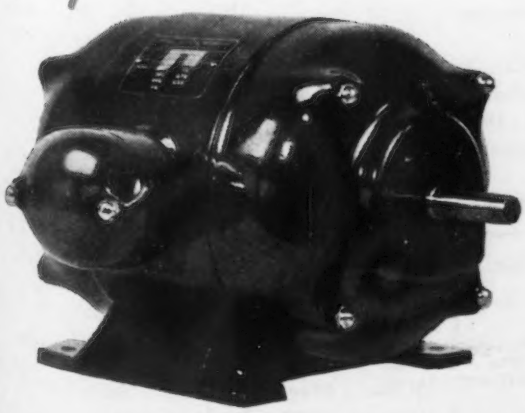
Preliminaries to hearing the steel wage case are being completed. While the United States Steel Corp. and several smaller cases have been certified to the Board, it is expected that all of the cases, more than 400 in all, including both steel makers and users, will be consolidated into one to expedite the proceedings. At best it promises to be long drawn out.

BOOBY-TRAP SCHOOL: ***These Britishers in Italy work blind through "Moascar Stocks" under supervision of experts, learning to handle booby traps and mines without being able to see them.***





Horsepower by Howell



The Howell Protected Type Motor, shown, gives complete protection against dripping liquids, metal chips and other falling particles. Completely streamlined — utilizing non-breakable steel frame — malleable or steel base — cast iron end plates and cast iron, weatherproof terminal box are standard construction features. Special horizontal and vertical mountings are available.

Available in sizes 5 H.P. and smaller.

SUPERINTENDENT: I'm counting sheep, worrying about my production problems, and you butt in!

HORSE: Super., I've got a suggestion — a hot tip —

SUPERINTENDENT: Come, come, be brief. I'm tired!

HORSE: Well, well, that's too bad. But Horsepower by Howell would put an end to all those electric motor problems in your plant. All Howell specialized motors and standard motors are engineered and precision-built for the *hard* jobs. Your jobs will be easy for these quality motors.

SUPERINTENDENT: Really? Maybe I can stop worrying.

HORSE: You bet you can! Folks quit worrying when they buy Howell Motors. They know they have a precision-built, properly insulated, quieter operating motor. With Horsepower by Howell in your plant, you'll sleep like a log.

Making postwar plans? Phone the nearest Howell representative or write the factory. Your inquiry will put our experienced engineering staff and complete facilities to work for you.

HOWELL ELECTRIC MOTORS COMPANY

HOWELL, MICHIGAN

Manufacturers of Quality Motors Since 1915

WLB Steel Wage Panel May Decide All Wage Demands Simultaneously

New York

• • • **The steel producing** subsidiaries of U. S. Steel Corp., and the USWA-CIO are marking time this week on the wage demand question, following the citation of the case to the War Labor Board. It is believed now that the WLB is in the final stages of setting up a panel to hear the union wage demands, and the panel will handle most of the cases at one time, requiring briefs from both companies and the union.

WLB already has the U. S. Steel refusal on the union's wage demands and Republic Steel Corp., has had its case certified by the WLB. Other companies that may soon have their position cited to WLB are Wheeling Steel Corp., and Youngstown Sheet & Tube Co. Meanwhile, U. S. Steel Corp., steel-making subsidiaries are carrying on negotiations with the union on those demands that do not involve increases in wage costs.

Inland Steel Co., deadlocked its negotiations with the USWA-CIO on Jan. 27, and appealed to the U. S. Conciliation Service for assistance and referral of the unresolved issues to the WLB. Points in dispute included the 17c. an hr., wage increase, severance pay, and a guaranteed weekly wage. In a letter of the U. S. Conciliation Service, Inland said several conferences had been held, and bargaining would continue on issues that had not yet reached a deadlock. The Conciliation Service would be advised as each of these further issues are settled.

E. G. Grace, president of Bethlehem Steel Corp., pointed out this week that the various demands of the union, with regard to Bethlehem steel making operations only, would cost the company about 34c. an hr. This figure of course, includes the 17c. an hr. demand, along with sick benefits, severance pay, vacation pay, etc.

Mr. Grace pointed out that while Dept. of Labor cost of living indices show an increase in cost of living of 23.5 per cent from Jan. 1, 1941, to date, average hourly earnings of Bethlehem steel workers increased 36.4 per cent and weekly earnings are up 50.6 per cent. However, it must be remembered that the Dept. of Labor index on living costs, while the only one of consequence that is available, is not too accurate, and the increases shown in Bethlehem steel workers' earnings include considerable overtime which could and will stop rather abruptly, just as soon as business drops off. This is one of the factors that the union would like to overcome with its current demands, thus enhancing its position after the war.

Meanwhile, Mayor Frank Lausche of Cleveland charged that Cleveland's industries are penalized through the faults of a minority. He stated that because 16 per cent of the area's plants have labor shortages, the entire area is tagged "critical labor shortage area" and is being penalized with contract restrictions. Actual shortages, he claimed, occur mainly in forge shops, foundries, and battery factories, according to a survey of 140 plants employing 168,000. USES figures show that the labor demand in that region fell from 17,000 per month last September to about 7000 needed for January.

Activities on the labor front this week were varied and widespread. Fulton Iron Works Co., St. Louis, petitioned WLB for a review of a vacation award granted AFL electrical workers by the regional WLB. This petition was denied. . . . U. S. Vanadium Corp. was denied a reversal of a WLB decision granting maintenance of union membership and the check-off to UMW workers at its Rifle, Colo., plant. Wayne L. Morse, WLB public member, reaffirmed the WLB Non-ferrous Metals Commission award, stating that WLB has the "indisputable authority to direct parties to wartime labor disputes to abide by maintenance of membership awards in cases wherein the Board deems it advisable to grant that form of union security."

• • • **Ordered back by** the WLB, 350 strikers returned to work at Bison Casting, Inc., Buffalo, after being out one week in a dispute over a board wage ruling. . . . The Buffalo-Niagara area War Manpower Committee ordered a subcommittee to investigate the use of Italian war prisoners as laborers in district war plants. Fierce opposition of labor members had previously tabled this move. However, three plants have requested Italian prisoners for pick and shovel work. German prisoners are not being considered for such work.

• • • **The Ford Motor Co.,** rolling mill was closed Jan. 31 by a strike growing out of a dispute over the docking of 15 min. pay of 38 men said to have quite work early last week. About 1000 joined in the walkout.

AFA Nominates Officers

Chicago

• • • **Ralph J. Teetor, president, Cadillac** Malleable Iron Co., Cadillac, Mich., was nominated to succeed L. C. Wilson, general manager, Reading Steel Casting division, American Chain & Cable Co., Reading, Pa., as president of the American Foundrymen's Association, at a recent nominating committee meeting. Fred J. Walls, International Nickel Co., Detroit, was nominated for the vice-presidency. Both the presidency and the vice-presidency are for one-year terms.

The following were nominated to become directors of the association for three-year terms: Frank J. Dost, Sterling Foundry Co., Wellington, Ohio; S. D. Russell, Phoenix Iron Works, Oakland, Cal.; R. T. Rycroft, president, Jewel Alloy & Malleable Co., Inc., Buffalo, N. Y., Joseph Sully, president, Sully Brass Foundry, Ltd., Toronto, Ont., and L. C. Wilson, general manager, Reading Steel Casting Div., American Chain & Cable Co., Reading, Pa., now president of the association.

The election of officers and directors will be held at the annual business meeting of the association, which will take place during the Third War Production Foundry Congress, Buffalo, N. Y., April 25 to 28. All nominees have been active in work of chapters of the association.

Price Briefs

• Amdt. 81 to MPR 120 revises maximum prices for bituminous coal at the mine or preparation plant in Western Kentucky and puts them on a simpler basis.

• Amdt. 3 to MPR 452 provides for the exemption from price control of the sale and delivery of truck axles by Timken-Detroit Axle Co. to the War Dept. (Release No. OPA-3869)

• Amdt. 1 to Food Production Order 14, Sup. Order 1, Rev. 1 lifts restrictions on distribution of certain farm machinery items.

• Amdt. 2 to RMPR 34 reduces prices on fence posts to railroads and other industrial consumers. (Release No. OPA-3865)

Steel Founders Elect Officers

• • • **The Steel Founders'** Society of America announced the election of officers and directors for 1944-1945. Officers elected were: Oliver E. Mount, American Steel Foundries, Chicago, president; F. Kermit Donaldson, Machined Steel Casting Co., Alliance, Ohio, vice-president; Col. Merrill G. Baker, Steel Founders' Society of America, Cleveland, executive vice-president; and Raymond L. Collier, Steel Founders' Society of America, Cleveland, secretary-treasurer. Members of executive committee elected were: Oliver E. Mount, chairman; A. M. Andorn, Penn Steel Casting Co., Chester, Pa.; T. F. Dorsey, Fort Pitt Steel Casting Co., McKeesport, Pa.

Important Advancement IN FERRO-ALLOY BRIQUETS

NOW . . . A FULLY USEFUL PROTECTIVE BINDER

THIS ACHIEVEMENT dispels the old belief that a pitch binder for ferro-alloys would melt when heated, resulting in a crumbling briquet. These OFA Briquets, during the heating operation, produce a carbon binder which protects the readily oxidized ferro-alloy up to its alloying in the iron. It is then consumed as part of the charge without producing an added refractory slag burden.

YEARS have been devoted to find this "ideal" binder. We have prepared an interesting brochure containing complete factual information with actual production tests that prove the advantageous utility of this entirely new metallurgical application to ferro-alloy briquet binding. SEND FOR YOUR COPY TODAY.

IMMEDIATE DELIVERY *in tonnages to meet your requirements. Ferro Silicon briquets containing either one or two pounds of contained silicon, Ferro Manganese and Ferro Chrome briquets containing 2 lbs. of alloy—shaped for easy storing—colored for easy identification.*

Campbell #302 Horizontal Abrasive Cutting Machine

CAMPBELL ABRASIVE CUTTING MACHINES HELP MEET LABOR SHORTAGE

According to WPB, the peak of the skilled labor problem has yet to come. • If you cut any of the annealed or unannealed steels, non-ferrous alloys, plastics, glass or ceramics—solid bar, tubular or flat stock—a CAMPBELL ABRASIVE CUTTING MACHINE will help you. • Tell the CAMPBELL Engineering Department materials, shapes, sizes, lengths before cutting, lengths of cut off pieces and hourly production required. They'll give you cost data and production procedure without obligation. *ASK* for a copy of the CAMPBELL ABRASIVE CUTTING CHART. It shows how the CAMPBELL complete line of Abrasive Cutting Machines can be used to open the way to new highs of production and new lows of cutting costs.

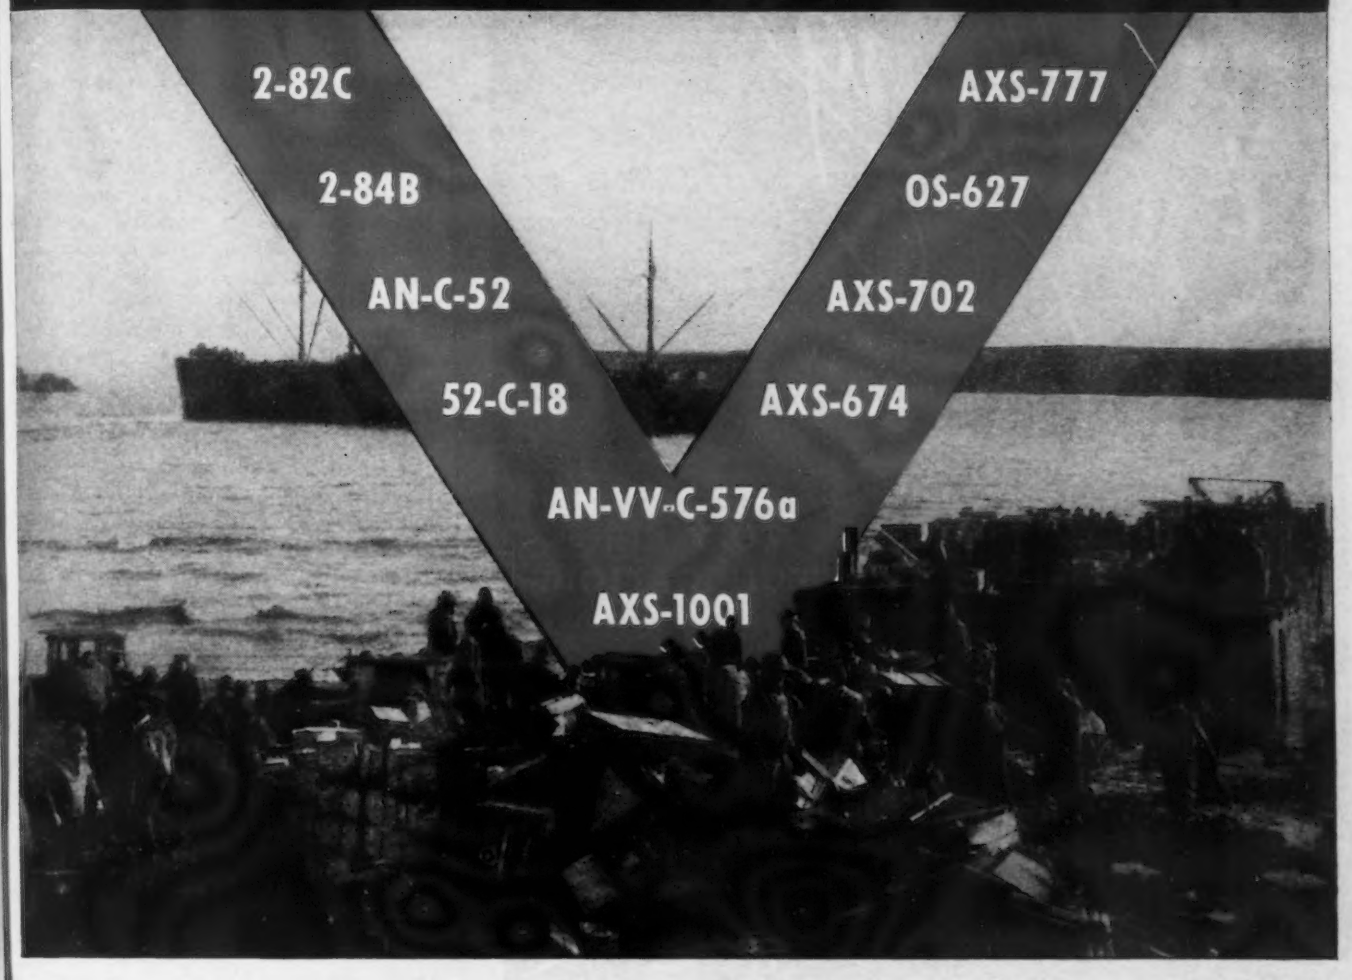
"SPECS" THAT SPELL PROTECTION



Everyone concerned with packaging of metals knows what the above symbols mean.

They are government specifications for protection of metal parts and equipment, such as you see piled in the foreground of this landing view. All over the world our armed forces are putting into action the products that industry has made so well and so fast during these frenzied war production years.

Will the contents of these packages be preserved, ready for immediate use when opened after long storage in damp climates? Uncle Sam says they must be, and has set up many "specs" as standards for packaging. The best known ones, for which there is most demand, are listed above.

E. F. Houghton & Co. supplies approved products to meet each one of those important specifications.

Ask the Houghton Man, or write direct for full information. And remember, please, that a concern making specialized oils and greases for 79 years has the edge when it comes to "beating," not merely meeting, today's crucial rust preventive requirements.

Broadgate Explains Stockpiling Bill

Cleveland

• • • At the recent convention of the Institute of Scrap Iron & Steel, W. C. Broadgate, technical consultant to the Senate Small Business Committee outlined Senate action on stockpiling strategic minerals including scrap metals. The bill under consideration, S.1582, was introduced by Senator James G. Scrugham, chairman of the Senate sub-committee on mining and minerals functioning under the Small Business Committee. Mr. Broadgate gave a resumé of the status of this bill.

The domestic mining industry seems to be generally in accord with the stockpiling idea and differences of opinion are largely those of detail. There is one major split in fundamental thinking and that is whether stockpiling should be achieved by acquiring metal from domestic sources or principally from foreign sources.

Objectives of the stockpiling bill are to assure an adequate supply of strategic and critical minerals for any emergency by holding intact all stockpiles owned by government agencies that survive the war and by augmentation thereof primarily from domestic sources.

The bill is designed not only to keep a nucleus of the domestic mining industry operating but also to accumulate large stocks of such materials for immediate use in the case of still another emergency. One feature of the bill would permit mining companies to work out their losses and offers a certain protection to the American mining industry.

Briefly, the Scrugham bill may be outlined as follows: (1) Mineral production from domestic sources will receive preferential price treatment. Only if the purposes specified in the bill cannot be fulfilled from domestic sources may any foreign purchases be made.

(2) For period of one year following termination of hostilities it is proposed to continue paying premium prices to those mines in which governmental assistance or investment, or private investment, is shown to have been made with intent and purpose of augmenting war or essential civilian production. Thereafter the *Minerals Stock Pile Control Board* set up in the bill may purchase domestic minerals at a price up to but not beyond the then current import price, duty paid, plus 25 per cent.

(3) Provision is made to continue

Put idle SCRAP to work . . . help speed Victory!

the receipt of foreign commitments where contracts which the government has made for such commitments cannot be terminated prior to the end of hostilities. Such minerals as they are received will be frozen in the stockpiles. It is also provided that minerals and metals which may be acquired by reverse Lend-Lease shall be added to the stockpiles.

These might be termed the anti-dumping provisions and no stockpiles may be released until Congress deems it actually to be necessary.

(4) Nothing in the bill shall prevent domestic producers from selling freely in the open market nor prevent industry from privately importing minerals at will at the current prices prevailing after the OPA ceilings are removed.

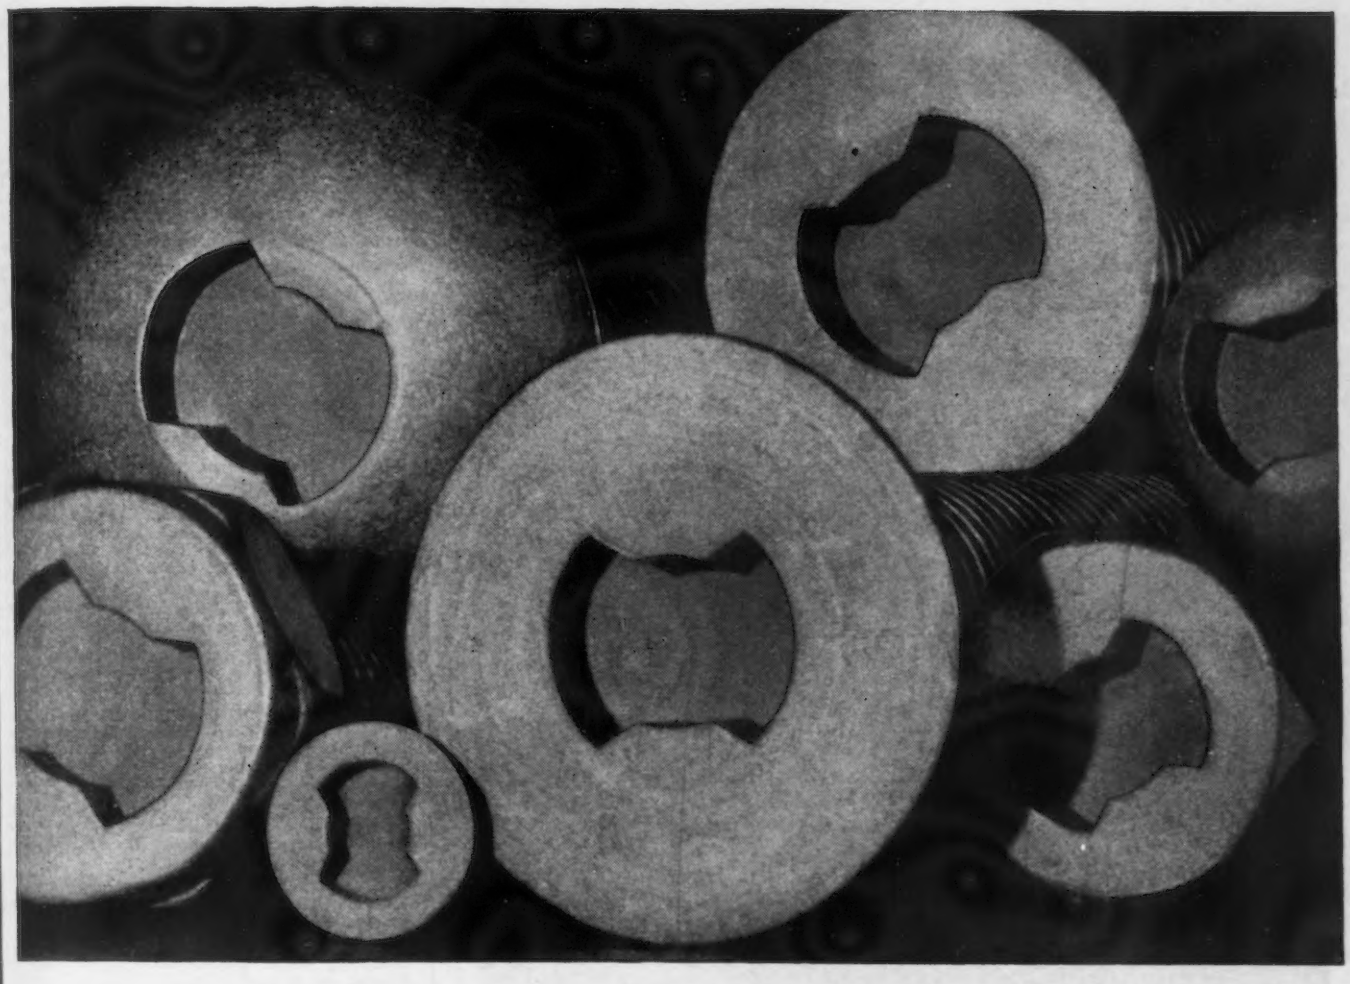
Ickes Releases 11 Mines to Owners; Still Controls 1909

New York

• • • **Of the 2385** coal mining companies that were possessed by the government on Nov. 1, 1943, under the direction of Coal Administrator Harold L. Ickes, because of the strike of the coal miners under the leadership of John L. Lewis, 1909 of these companies are still under government possession and control. A total of 476 mining companies have had their properties released following the release of 11 during the past week. These companies were:

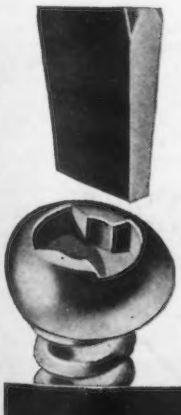
Chloe Elkhorn Coal Co., Pikeville, Ky.
W. A. Barnes, Masontown, Pa.
Lindey Bros. Coal Co., Slippery Rock, Pa.
C. D. Moore Coal Mine, Portersville, Pa.
Chas. D. Morris Coal Co., Harrisville, Pa.
William Piccolomini, Connellsville, Pa.
Simon W. Rider, Charleroi, Pa.
H. W. Smith, Lake Lynn, Pa.
Tri-County Fuel Co., Youngstown, Ohio.
Thomas J. Wolf, Lake Lynn, Pa.
Young & Taylor Coal Co., Oakdale, Pa.

Ickes claimed this week that an opinion from Attorney General Francis Biddle indicated that the Smith-Connally "Anti-Strike" act does not require the government to relinquish possession at this time of the coal mines seized in the November strike. While the act provides that the mines should be returned to the owners not later than 60 days after the restoration of the productive efficiency prevailing prior to government possession, the Attorney General ruled that "productive efficiency has not been restored within the meaning of Section 3 of the War Labor Disputes Act" even though the tonnage being produced may be equal to or exceed that of the period prior to the Government take-over. Physical volume of coal produced is not alone the determining factor.



They "Cancel-Out" a lot of Handicaps

The phrase isn't ours. It comes from the assembly lines . . . where new factors for speed, safety, simplicity, and lower cost are rated high. CLUTCH HEAD Screws "cancel-out" the handicap of slow-down hesitation. The wide roomy clutch offers an easy bull's-eye target for the "greenest" operator, inviting speed born of confidence . . . the automatic entry of the Center Pivot Driver into dead center of the recess speeds and eases the drive home . . . and that same definite torque grip assures the operator there is no hazard of slippage. Then there is the CLUTCH HEAD Lock-On feature which nullifies the handicap of fumbling around hard-to-get-at spots by uniting screw and bit as a unit for easy one-handed reaching. In field maintenance, too, CLUTCH HEAD simplifies operations by solving hitherto accepted problems. Service men prefer this modern screw because it may be operated with the ordinary type screwdriver . . . even with a piece of flattened steel rod in an emergency. They know also that, where screws have to be removed, saved, and used again, the CLUTCH HEAD Lock-On feature obtainable with the Center Pivot Hand Driver "cancels-out" the serious handicap of dropped and lost screws.



Get personally acquainted with these many exclusive features. Send for assortment of CLUTCH HEAD *Screws, sample Center Pivot Bit, and fully illustrated Brochure.*

CLUTCH HEAD Screws are contributing importantly to many phases of the war effort. They are available in Standard and Thread-forming types for every purpose . . . production backed by the extensive resources of this Corporation and by responsible Licensees.

CLUTCH HEAD · SCREWS ·

ECONOMY is an important feature of this Center Pivot Assembler's Bit. No "back-to-the-factory" shipment is necessary for reconditioning. A brief application of the end surface to a grinding wheel fully restores original efficiency.

UNITED SCREW AND BOLT CORPORATION

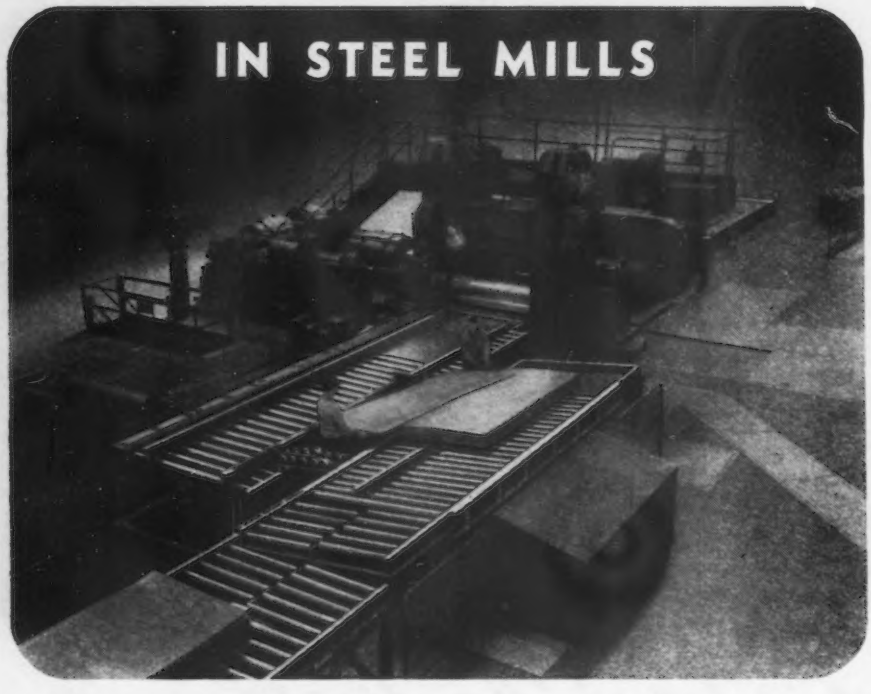
Logan Conveyors

HAVE PROVED

their worth

IN STEEL MILLS



IN THIS great steel mill, as in many others thruout the nation, a Logan handling system daily proves its superiority by eliminating waste of time, motion, space and — above all — irreplaceable man-hours. Here the power-driven Pack Tilter (adjustable up to 30°) aids manual transfer of sheets to the chain-driven, live-roller type Entry Conveyor serving temper mill. Sheets are delivered by belt conveyor to Roller Leveller, thence to Piler and Roller Gravity runout. Whatever your handling requirements may be, Logan engineers can help you meet them with maximum efficiency and economy. Write Logan Co., Inc., 545 Cabel, Louisville, Ky.

May We Send You This Book?

Our Catalog No. 22 may prove of untold value to you. It is full of illustrations and descriptions of many Logan Conveyor installations in actual steel mill operation. Ask for it.

PUT *FLOW* INTO PRODUCTION

Metal Fastening Equipment Listed In Enemy Patents

• • • **The thirteenth** list of seized enemy patents available on license from the Alien Property Custodian, bolt, nut, rivet, nail, and screw manufacturing equipment and accessories are covered. This series of seized patents started in the Nov. 4 issue of THE IRON AGE where information on rules and procedures was shown.

In the items shown, the sub-class number appears first, followed by the patent number, description, inventor's name and nation, and date of patent issuance. The patent description in full may be acquired from the Government in the manner described in the Nov. 4 issue of THE IRON AGE, page 95.

Class 10—Bolt, nail, nut, rivet, and screw making

(1) 1,816,282. Method and tool for securing wire screw-threads to wooden members. W. Heyner and H. Henkel, Germany. 7-28-31.

(2) 1,682,646. Machine for the production of wood screws from pressed blanks by slitting the bolt head, turning off of the head surfaces and cutting of the thread in the shaft. G. Weber, Germany. 8-28-28.

(5) 1,735,231. Screw-slotting mechanism for producing slots or incisions in the heads of screws or similar parts. L. Braren, Germany. 11-12-29.

(8) 1,624,746. Automatic machine for making the heads of slotted wooden or iron screws. K. Kumpmann, Germany. 4-12-27.

(10) 2,129,290. Method and apparatus for producing screw threads by cold method by forging by means of hammer jaws movable radially to the blank and provided with a female screw thread corresponding to the screw thread to be formed. W. Trurnit, Germany. 9-6-38.

(24) 1,618,445. Means for cold upsetting or heading blanks in the manufacture of set screws, cap screws, rivets, bolts, and similar headed articles. J. Kuhne, Germany. 2-22-27.

(24) 1,743,564. Ejecting implement for cold-pressed headed bolts. K. Nagel, Germany. 1-14-30.

(26) 1,918,910. Device for controlling the vertical slide on double acting bolt presses. C. Hilgeland, Germany. 7-18-33.

(27) 1,618,446. Method of manufacturing cold rivets, screw-blanks and similar headed articles by means of which a very great length of the stock or rod can be upset to form the head so that the size of the head for a certain diameter of material is almost unlimited. J. Kuhne, Germany. 2-22-27.

(27) 1,903,245. Manufacture of blanks and similar articles with jumped heads and more particularly to wood screws. M. Ruska, Germany. 3-28-33.

(27) 2,060,593. Method of producing a homogeneous metal element having a reduced portion which serves to increase the fatigue

What will your future **I.P.** *be?*

†† This is the Second of a series of advertisements presenting "Industrial Par" and its importance to your company in all future planning. Save this and succeeding I.P. advertisements as the basis for discussion and as a guide to your planning program.

So much from so little

The Annual National Investment* in machine tools represents only 2% of the total value of products produced by machine-tool-using industries.

YES — in the ten peace years 1927 to 1937 — the builders of machine tools produced a yearly average of 122 million dollars worth of equipment for American industry. The industries that bought and used these machine tools were able to produce an average of about 9 billion dollars worth of peacetime products annually in those same years. The annual investment in machine tools represented only about 2% of the total value of products created by these machine-tool-using industries — the makers of engines and turbines, agricultural and construction machinery, automobiles, planes, locomotives, household appliances and many other useful things.

In terms of productive power this is impressive — certainly "very much from very little." But what significance have these rather startling ratio "figures" to industrial management? Industrial statistics show that the national output per man-hour tends to increase constantly — its previous rate of 2½% per year compounded can be expected to advance to 4% or 50% increased output per man-hour every 10 years.

Manufacturers who intend to keep step with a high level of national prosperity — the volume production which means more goods for more people at lowest cost and security of jobs and wages for the greatest number of workers — must strive to attain the 50% increased output pace. Certainly full advantage must be taken of the inherent ability of machine tools to achieve the most with available man-hours, for only with the most modern machine tools can any manufacturer hope to compete successfully over a period of years as well as make workers' jobs safer, easier, and more productive.

Isn't it only logical to equip your plant with machine tools — those possessing the greatest sustained productive power, the ability to produce fast, accurately at lowest cost — the better to win your race with competitors in the world of peace production to come?

Back the attack **BUY MORE BONDS**

Spotlight facts for your future I.P. *planning*

* Production methods — developed in wartime — increase man-hour output; pent-up buying power — released in peacetime — demands increased production.
* The rate of 2½% increase per year output per man-hour, established by a 12 year record of industrial production, can be expected to reach at least 4% per year — compounded.
* Manufacturers must set a goal of 50% increased output per man-hour every 10 years — to maintain a high level of national prosperity and achieve its benefits in terms of security of jobs and wages for the greatest number of workers and the volume production of more goods for more people at lowest cost.
* Machine tools — the most modern, most efficient — are recognized as the most effective implements of mass production and increased output at lowest cost — but only continual replacements with the newest and finest machine tools assures full productive capacity. *Such replacements yearly should be equal to 10% of the total machine tool investment — in keeping with increased output.*
* The cost of machine tools is insignificant in terms of their productive power . . . from 1927 to 1937, according to census reports, American manufacturers had only a total of about 2% invested yearly in machine tools in ratio to a total volume of 9 billion dollars' worth of production annually.

†† **Industrial Par** — *the constantly increasing output per man-hour equal to approximately 50% every 10 years.*

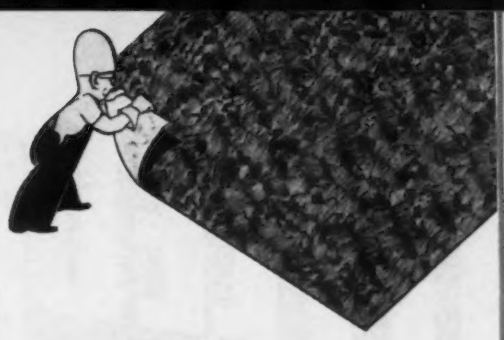
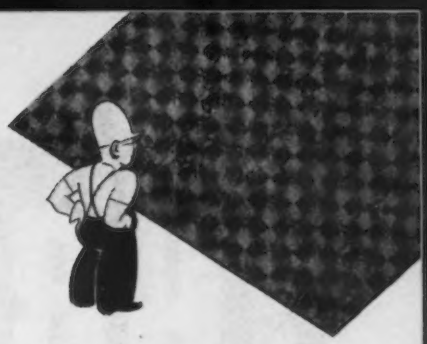
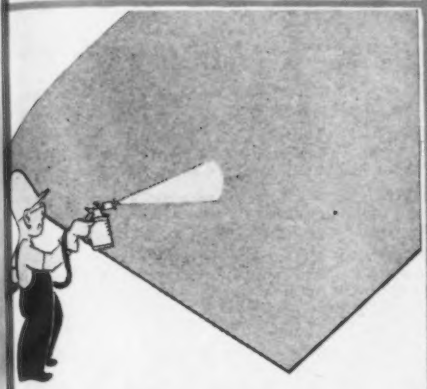
SUPERIOR GALVANNEALED
A special quality steel sheet that takes and holds fine finishes. Rust resistant. Easily fabricated, easily soldered.



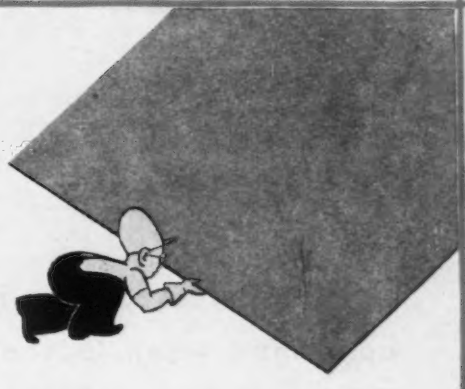
SUPERIOR GALVANIZED
A bright - spangled, commercial galvanized sheet with exceptionally good working qualities. Soft tempered and uniform.



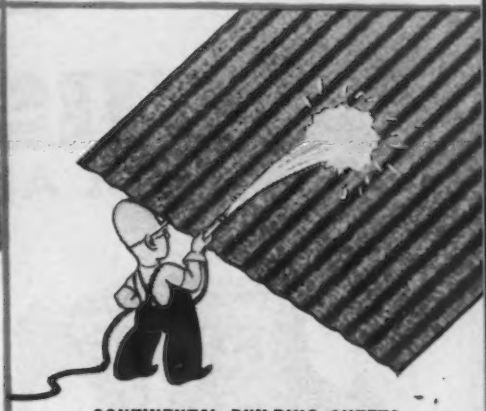
SUPERIOR CHECKERCOAT
Galvanized by the Superior Process with distinctive bright, checkered spangles. Pleasing to look at, fine to work with.



CONTINENTAL LEAD SEALED
New lead-alloy coated sheet resists rust longer, "takes" and "holds" paint, solders more easily. Fine for die-forming.



SUPERIOR LONG TERNE
A favorite with manufacturers. Open hearth steel base, tempered for accurate forming. Takes paint, resists rust.



CONTINENTAL BUILDING SHEETS
15 styles of modern steel roofing and siding including TYL-LYKE, Corrugated, V-CRIMP. All galvanized by the Superior Process.

If you don't see what you want

Ask for it!

Our production includes steel sheets with more than thirty different types of finishes, coatings and surface treatments—all made in our own mills from open hearth steel from our own furnaces. Postwar production will have no place for "jack-of-all-trades" steel sheets. That's why nearly every Continental and Superior sheet is a specialty, its properties designed to fit the requirements of a definite class of duty. If you are "shopping around" for steel sheets to meet particular wartime needs, or to fit exacting future plans, it will pay you to get full information about Continental-Superior sheets.

(154) 2,189,867. Method of and apparatus for forming internal threads in a workpiece. G. Hagerman, Dayton, Ohio, assignor, by mesne assignments, to Societe d'exploitation des Brevets Moineau, Luxembourg. 2-13-40.

"IT'S A RAFFLE, THE WINNER GETS A SEAT ON THE BUS IN THE MORNING!"

A Completely Equipped Foundry has been added to Brake Shoe's Research Group

Vital war work demanded a full-scale foundry for experimental castings.

Such castings might be piloted in a production plant, but this would interfere with regular work.

Today this full-scale experimental foundry is ready for operation as part of Brake Shoe's Research Group.

To house this foundry, an unused factory building had to be dismantled and moved from Kansas City, Kansas, to Mahwah, New Jersey.

If engineers can take new ideas in foundry practice direct to the foundry and get all the kinks out before going into regular production . . .

It should effect important time savings.

It should accelerate necessary field testing and develop improved methods.

In addition to current concentration on problems directly connected with wear, experienced metallurgists and engineers of this Research Group are constantly working to improve products and production methods.

If you have a "punished part" problem, either in the structural or production phase, Brake Shoe's expanded research facilities should be helpful. They are available to manufacturers whose production calls for large runs of standardized parts.

Is Brake Shoe On Your Parts Source List?

Because many of the millions of parts produced by Brake Shoe for war have equally important peacetime uses, Brake Shoe will be ready for parts assignments in volume, the moment victory is won.

"fingertip"

control

1.—Each of three switches assembled in a strong, light, dust-tight case, consists of two buttons, assembled as a unit. One switch controls the travel of the crane along the runway; another controls the movement of the hoist along the single beam of the crane, while the third switch regulates the up and down movement of the hook.

2.—Each button, as it is pressed inward, makes 5 electrical contacts, corresponding to 5 independent speeds in each direction of rotation.

3.—Emergency stop switch located at lower end of assembly opens all circuits.

means fast, accurate load handling

Shepard Niles Electric Cranes & Hoists go to work on the toughest handling jobs by simply pushing a button. Loads are lifted, conveyed, deposited—swiftly and safely—rehandling is eliminated—operating costs materially cut.

With dependability and accuracy, Shepard Niles selective, 5-speed, push-button control is master of every crane or hoist movement, whether accelerating or decelerating.

Shepard Niles Single Beam Cranes are available in "Push-type", "Hand-racked" and "Motor-driven" types of crane propulsion, in Over-running, Inner-running or Under-running construction. Capacities from ¼ ton to 10 tons.

MAINTENANCE MANUAL—FREE ON REQUEST.
Describes maintenance of Shepard Niles Cranes & Hoists—amply illustrated with line and sectional drawings. 106 pages.

CRANE & HOIST CORPORATION

356 SCHUYLER AVENUE • MONTOUR FALLS, N. Y.

Briefly Told—

• A new industrial film, just released by the Cooper-Bessemer Corp., traces the development of the firm's engine production from its beginning 110 years ago to its present position as one of the foremost producers of Diesel and gas engines, compressors and foundry castings. The film is entitled "Continuous Performance" and skillfully blends important occurrences and dates in history with advances made by the company.

•

• Under the sponsorship of the Industrial Hygiene Foundation, Pittsburgh, a survey has been made of the health problems of women in industry. The study covered 54 plants in 10 states. While absences due to sickness were higher for women than men, accident rates on the whole were lower for women than for men. The problem of fatigue, common to married women with young children, due to lack of proper rest and recreation, has been alleviated in certain areas by the establishment of day nurseries. At present women can fill about 80 per cent of the jobs formerly held by men, and the outlook is they will continue in greater numbers, for the duration of the war. It is believed that they have made themselves a permanent place in industry, and that in the postwar period a greater number will be in industry than had been the case in the previous pre-war era.

•

• Dr. Harvey N. Davis, president of the Stevens Institute of Technology, announced the organization of the Stevens Research Foundation, a non-profit corporation to carry on scientific and industrial research in cooperation with the College. The Foundation is an outgrowth of the extensive program of research which Stevens has carried on in recent years which has expanded greatly during the war. Several of its laboratories are now engaged in confidential research for Government departments to aid the war effort, and they have also helped industry to increase and improve production in both war and peace.

•

• A new industrial instrument maintenance and repair course will be started on Feb. 1 by the Training School Division of Brown Instrument Co., Philadelphia. Changes have been made in the general outline of the course, especially that having to do with instructions in the two types of potentiometers, mechanical and electronic. The two types will be treated as separate subjects to make it easier for students to absorb the basic principles of each, and to meet the requirements of customers who send students to the school for the specific purpose of receiving continuous balance instrument instruction.

SMITHway Electrodes in Action
A huge, all-welded machine structure, one of hundreds of jobs being done in the Smith plants to back the boys in battle.

It takes more than theory to make GOOD WELDS!

Theory has an important place in the development of any welding electrode. But theory only means something to you after it has been *proved in the shop.*

Right there you have the difference between SMITHway Certified Welding Electrodes and the run-of-the-mine variety.

We may *start* the development of an electrode on a theory—but *we don't stop there.* After the theory . . . after the research work . . . after the laboratory tests—then comes the showdown! The electrode goes out into our welding shops. There it is put through its paces *under actual shop conditions.* If it proves successful there, it has what it takes to prove up anywhere!

That is the kind of electrode we offer you in *SMITHway Certified Welding Electrodes.* There's theory back of them. There's scientific laboratory research and testing back of them. But best of all—they're *shop-tested* because what we want from an electrode is *better welds.*

That's what you want, too—isn't it?

Mild Steel...High Tensile...and Stainless Steel
WELDING ELECTRODES
made by welders . . . for welders

SMITHway Welding Monitor *cuts time cost of training welders as much as 33⅓%!*

SMITHway AC Welding Machine *—no arc blow; reduces spatter losses; saves power.*

CUTTING FLUIDS DESERVE YOUR SERIOUS ATTENTION

Well informed authorities have made the statement that more intelligent application of cutting fluids and better tool grinding would make possible a 30% increase in metal-working production. In these days of man-power shortage, what a challenge that statement presents!

Be honest . . . in your plant are cutting fluid problems given the attention they deserve? Are your performance records accurate? Are you aware of what better cutting fluids can do for the job? Or is your attention centered on other fields until real trouble develops which might be traceable to improper use of cutting fluids? Hundreds of metal-working plants are getting the most out of their cutting fluids by working closely with the Stuart service engineer. They know that there is no universal cutting fluid, no magic compound—but when a Stuart product is put on the job they are sure they have every cutting fluid advantage that broad engineering experience and "know how" can give them.

A REQUEST OF STUART CUSTOMERS

Containers of all types are critically scarce. We urge you to cooperate with the W.P.B. program to conserve containers by observing these four rules for handling drums:

1. Do not drop.
2. Use a little oil to avoid stripping threads in removing plugs.
3. Replace plugs carefully when drum is empty.
4. Keep drums under cover when emptied.

To be sure you have all the advantages, work with the Stuart service engineer, representing a company which has specialized in metal-working lubrication since 1865.

We invite you to write for our new free booklet, "The 577th Oil," which contains twenty-two case histories, typical examples of how Stuart engineering is solving production problems (like your own), as well as other valuable metal-working data. State your name, company and title.

NEWS OF INDUSTRY

in top production ideas during 1943 at General Electric plants, and were well represented in the leading awards. The year's awards for accepted manufacturing suggestions were 47 per cent above the previous year's all-time G-E high. During 1943 the company accepted 23,841 as against 16,204 for 1942. The amount paid suggestors was $276,760 against $158,943 for the previous year, highest totals since the G-E suggestion system was established in 1906.

●

• ***Cutler-Hammer, Inc., Milwaukee, has completed settlement of its renegotiation of war contracts with the government on 1942 profits, resulting in a net adjustment of $948,352.50 in favor of the government. This will be charged against reserves of $1,250,000 which the company set up out of 1942 earnings and therefore does not reduce net profits shown for that year.***

●

• In the annual report for the fiscal year ended Oct. 31, 1943, Foote Bros. Gear and Machine Corp. reported net income of $858,303 after charges including a reserve of $750,000 against renegotiation of war contracts. Because renegotiation refunds are so indeterminate, no effort has been made to compute per share earnings. It compares with net income for the previous fiscal year of $686,114 after renegotiation refunds.

●

• Keystone Steel & Wire Co. reports for the three months ended Dec. 31, 1943, the second quarter of the company's fiscal year, net profit of $490,568 after all charges including federal income and excess profits taxes. For the six months ended Dec. 31, net profit amounted to $726,720, or 96 cents a share, compared with $456,931, for the same six months of last year.

●

• **The first instances of release of mechanics from war plants to local automotive service garages in the Springfield, Mass., area is noted. In each instance the mechanics originally worked in the garages, but left for more money in war plants. Now that overtime in many war munition plants has been drastically cut, the mechanics are anxious to get back on their old jobs.**

●

• Topping the list of misunderstandings regarding WLB rules, according to a recent check made by the Research Staff of the Labor Relations Institute, is the provision requiring "equal pay for equal work." Pointing out that this regulation does not apply to jobs which have been traditionally performed by women, the Institute reports that a woman worker is entitled to the same rate of pay as a man if the following three conditions are fulfilled: (1) The job must be the same as the one being performed by a male worker. (2) The women must turn out the same quantity and quality of work as the male worker. (3) The particular job in question, now being done by a woman, must once have been performed by a man for the same company.

●

• ***Ten plants produced 200 per cent more of the Army's new carbines during November than the combined production of Springfield and Enfield rifles in the record month of World War I, according to Col. Frank J. Atwood, chief of the Rochester (N. Y.) Ordnance District.***

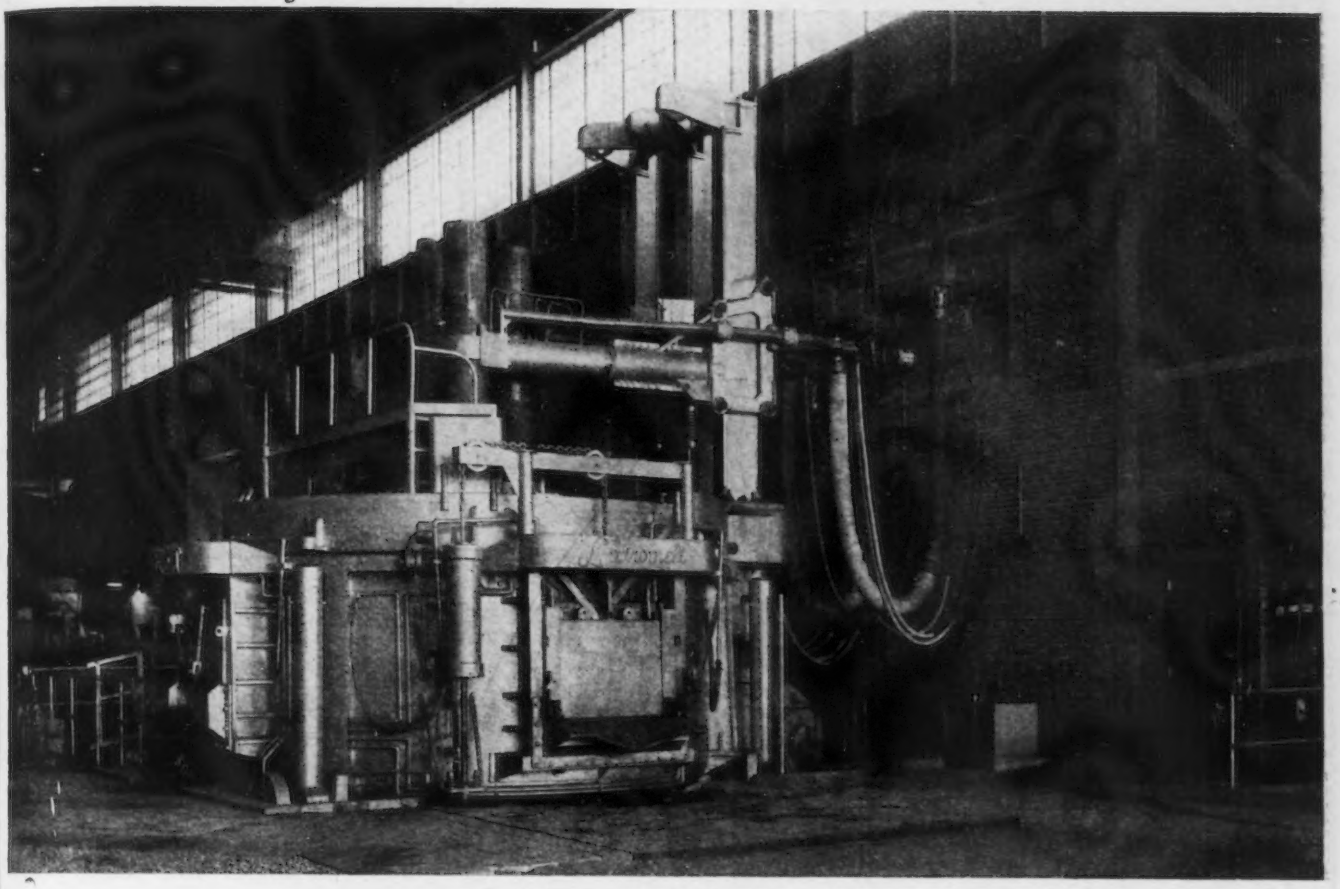
• The Western Pennsylvania Safety



the Furnace of today and tomorrow

The illustration shows, in normal operating position, one of the largest top charge type electric furnaces in the United States. This is a 17' diameter, size KT, 50 ton capacity Lectromelt, and is now in production on alloy steel. Similar capacity Lectromelts are pouring plain carbon steel. This furnace is of the top charge type, in which the roof is raised hydraulically, and rotated to one side for quick charging with a drop bottom bucket. Both a main working door and an auxiliary side working door are provided for convenience in working a heat.

Top charge type Lectromelts increase steel production. Their use results in lower power consumption, lower electrode and refractory costs and increased tonnage per man hour. Top charge type Lectromelt Furnaces are built in standard sizes ranging from 100 tons down to 250 pounds capacity. Their rugged construction gives maximum production and long life. Write for complete information on Lectromelt Furnaces to meet your melting requirements.

WORK BENCHES... NOT PARK BENCHES

Last year about 700,000 men came back from the armed forces. This year it is estimated that there will be over 1,200,000.

These men will have to be classified, tested and trained. Some who are partially disabled will need special help. All will need some sort of work. That is a promise Uncle Sam has made to these boys.

Your first thought is going to be, "With the cutbacks we'll get, and our reconversion problems, our plant can't possibly re-employ many of these men." You'll be absolutely right. Right here is where we need some new terminology in our economic setup.

In my opinion, "Industry" should be defined as that portion of our economic system that creates and produces. This takes in factories, farms and mines. The word "Business" should include that portion that has to do with transporting, selling, distributing and servicing the merchandise and goods that are produced. It also includes the professions and communication.

Now, if we go into past history on that basis, we find that "Industry" has never accounted for more than approximately one-third of all of the gainfully employed people in the United States. "Business" has accounted for the other two-thirds.

Yet "Industry" will be blamed for any failure to solve the postwar employment situation. Industry simply cannot sit back and let someone else try to figure out the solution.

The job is too big for Government. Even with the best intentions in the world, Uncle Sam, sitting in Washington, doesn't know your community. This is a community job. And if it isn't done right—*you'll* be blamed for it.

Geo. D. Trundle Jr.
President

1919-1944

Council, Pittsburgh, elected Charles R. Cox, president of National Tube Co. and of Tubular Alloy Steel Corp., U. S. Steel subsidiaries, as its president, to succeed Raymond A. Tucker. Mr. Tucker will continue as a director of the organization. Six vice-presidents were elected. They are: D. P. Hartson, vice-president, Equitable Gas Co.; F. Rhodes Henderer, Carnegie-Illinois Steel Corp.; J. P. Leonard, Blaw-Knox Co.; Donald M. McNeil, traffic engineer, City of Pittsburgh; Dr. E. A. Dimmick, associate superintendent, Pittsburgh Board of Education, and L. J. Bowker, Mine Safety Appliances Co. M. C. Conick, Main & Co., was elected treasurer, and E. J. Kreh, reelected secretary. The 20th annual Western Pennsylvania Safety Engineering Conference will be held in April.

•

• Production achievements of the valves and fittings industries were praised by Capt. J. O. Gawne, director of the Shipbuilding Division, WPB, at a meeting of representatives of these industries in New York. The meeting was called by WPB to review production problems. The valve industry has expanded its steel valve output to approximately seven and one-half times its pre-war level. Last year the industry produced valves of steel and other metals to an estimated total of 277,525 tons, or more than 99 per cent of stated 1943 requirements.

•

• *Bethlehem-Hingham Yard, recently discontinuing Sunday work, on Feb. 1 will eliminate its 11 P.M. to 7 A.M. shift, thereby bringing operating schedule down to two shifts. Also on Feb. 1, it will start discharging 10,000 workers.*

•

• **Because self-propelled ships are now available in sufficient numbers to handle cargoes of strategic bauxite, base of aluminum, a contract for construction of 26 non-propelled concrete barges has been cut to 20, the U. S. Maritime Commission announced. The contract is held by Barrett & Hilp, South San Francisco, Cal. Allocation to the Army, Navy, and the West Coast grain trade has taken care of the 20 already built or under construction. No use being found for the other six, their keels will not be laid.**

A.I.M.E. Schedules Its Forthcoming Meetings

• • • **Forthcoming meetings** of the American Institute of Mining & Metallurgical Engineers have been scheduled as follows:

April 20, 21—Twenty-seventh Annual Conference of the Open-Hearth Steel Committee and Blast Furnace and Raw Materials Committee, Iron and Steel Division. Pittsburgh.

Oct. 5, 6—Second Annual Conference of the Electric Furnace Steel Committee, Iron and Steel Division. Pittsburgh.

Oct. 16, 17, 18—Regular Fall Meeting, Iron and Steel Division and Institute of Metals Division. Cleveland.

Oct. 27, 28—Annual Fall Meeting, Ohio Section of Open Hearth Committee and Ohio Valley Section. Columbus, Ohio.

It's the "little" things . . . The successful completion of today's *big* war projects depend on "little" things . . . Like rugged floors that withstand punishing hours of wear . . . Safe floors that prevent costly falling accidents. "A.W." Rolled Steel Floor Plate can be cut and installed almost overnight without disturbing production. Illustrated is the "A.W." Super-Diamond Pattern which resists slipping in *any* direction. Oil-proof, heat-proof, fire-proof, crack-proof. Write for folder.

Other products include Plates, Sheets, Billets, Blooms, Slabs—Carbon, Copper or Alloy analyses.

Hand Service Tools Shipments Total $8 Million for 11 Months

• • • **Shipments** of mechanics' hand service tools in the first eleven months of 1943 averaged over $8,000,000 a month, compared with approximately $6,000,000 a month for the corresponding period of 1942 and monthly averages of $2,000,000 and $2,300,000 in the pre-war years, 1939 and 1940, according to the Tools Division of the WPB. In addition to the huge demand from war factories, these tools are needed in large quantities for repair kits on aircraft, on tanks, jeeps, and other military vehicles, in ship repair rooms, at advance bases, and at air fields, and in other direct military uses.

Data for 1942-1943 cover approximately 150 manufacturers who ship over 90 per cent of the mechanics' hand service tools (pliers, wrenches,

etc.). Wood-working tools, edge tools, and such heavy forged tools as sledges, crowbars, etc., are excluded.

War Pushes Electronics 20 Years Ahead of Applications

New York

• • • **Electronic research** under the impetus of the war has beaten a scientific path into the 1960's and created a vast reservoir of technique that waits to be tapped by the demands of the public and industry, Walter Evans, vice president in charge of the radio division of Westinghouse Electric & Mfg. Co., stated.

At Westinghouse alone, war radio equipment output has been stepped up to 51 times pre-war volume. Most pre-war problems are now subject to adequate solution because of improvements, simplification, and the use of multiple purpose circuits; of various types of automatic controls; of tubes using new elements and new principles; and of frequency bands opened up many times wider than the whole available spectrum when the war began.

Industrial electronics such as plastics curing, dehydrating, and reflowing tin on electrolytically coated tin plate, have also been rather recent developments.

Weirton Uses Du Pont Halogen Electro-Tinning

Wilmington, Del.

• • • **One of the first** large installations of the E. I. du Pont de Nemours & Co., electrolytic tinning lines called the Halogen tin process, at Weirton Steel Corp., Weirton, W. Va., is now operating at full capacity. The Halogen tin process (described in THE IRON AGE, April 9, 1942, p. 115 and April 30, 1942, p. 35), is used in continuous high speed tinning of steel strip. Du Pont claimed at that time that strip steel for containers could be tin plated twice as fast with less electric power by this slightly acidic process than by alkaline electrotinning methods, and bath sludging is eliminated.

Tin deposited by this process can be heated without discoloration either when the tin plate is heated to obtain a bright finish (thermal reflowing) or when treated during the process of applying lacquers or enamels. Furthermore, at operating speeds of 1000 ft. per min. through the chemical baths, the thicknesses of the plate can be varied from 0.1 to 0.5 lb. per base box of tin plate.

The thinnest plates possible by the "hot dip" method require about 1.25 lb. of tin to cover 435.4 sq. ft. of base metal surface, the standard unit of measurement in the container industry. By the Halogen process, and quite possibly by other electrolytic tin plating methods, tin required amounts to only 0.25 lb. per 435.4 sq. ft. of base metal. Weirton, at present, is using abount 0.5 lb. of tin per unit of base metal surface.

One of the Weirton lines is operating at 1050 ft. per min., with the metal being in the 24 cell tin electrolyte bath some eight seconds. The process is continuous, with each coiler accumulating 25,000 lb. of coated strip, and then the strip is directed onto a second or alternate coiler.

Non-CMP Material Requests To Be Made on New Form

Washington

• • • **WPB warned** business firms and individuals who normally apply for priority assistance on WPB Form 541 for the acquisition of equipment or materials other than controlled materials, that effective Feb. 1 only applications made on the new revised version of that form will be considered. The old form, PD-1A, will be honored only until Feb. 1.

Toasters May Share Shelves with Wheaties

Buffalo

• • • **General Mills, Inc., is reported planning to make electric irons, toasters and waffle irons for sale in neighborhood groceries after the war. Presumably it will use its present ordnance shops for such production. The appliances may be offered as premiums. For two years General Mills' mechanical division has been producing special precision Navy equipment.**

Committee to Aid in Production Shifts

Washington

• • • **In preparation for** shifts in war production and to eliminate as many bottlenecks as possible that might result, WPB established a committee for identifying critical products. This action was taken upon the recommendation of the Requirements Committee and all the claimant agencies are requested to cooperate.

The committee will aid in eliminating material and component bottlenecks, identifying those products (including components, materials, and producers' supplies and equipment) which limit or prospectively limit the completion of approved programs, and directing the attention of the responsible claimant agencies and organizational units of the WPB to the need for remedial action.

The committee is to maintain constant contact with all claimant agencies and Industry Divisions who shall report evidences of bottleneck areas and in other needful ways cooperate with the committee. Recommendations of the committee shall be recommendations of the chairman, who shall also indicate any major differences of opinion developed by committee discussion. The committee is to:

1—Prepare and keep current a list of critical products based on:
(a) a working definition of critical products formulated by the committee. (b) evidence from procurement officials and other field sources as to difficulties of procurement, and (c) other relevant information on supply-demand positions in currently or prospectively critical products.

2—With respect to these critical products, direct the attention of the responsible claimant agencies and appropriate WPB organizational units to the need for a possible means of remedial action within their respective jurisdictions.

3—With respect to products no longer critical, direct the attention of the responsible agencies to the possible desirability of relaxing existing controls.

4—Identify individual bottleneck plants and recommend their inclusion in the several general categories of appendix A to program determination No. 500.

THIS 24" x 32" WALL CHART GIVES ROCKWELL, BRINELL, SCLERO, VICKERS HARDNESS AND TENSILE STRENGTH CONVERSIONS

• If you are a production executive whose responsibility includes the hardness testing of metals, you will certainly want one of these new charts for your office, shop, or laboratory. Handsome in appearance, printed in three colors, with the very minimum of advertising, it will prove its value every hour of every day. Type is large, easily read at a distance of several feet, yet the chart itself is only 24" wide and 32" high—about the size of a calendar.

Although a chart like this is relatively expensive to produce, and the quantity is rigidly limited, a copy is yours—free for the asking—if you request it on your letterhead.

Write Dept. IA, CLARK INSTRUMENT, INC., 10200 Ford Road, Dearborn, Michigan.

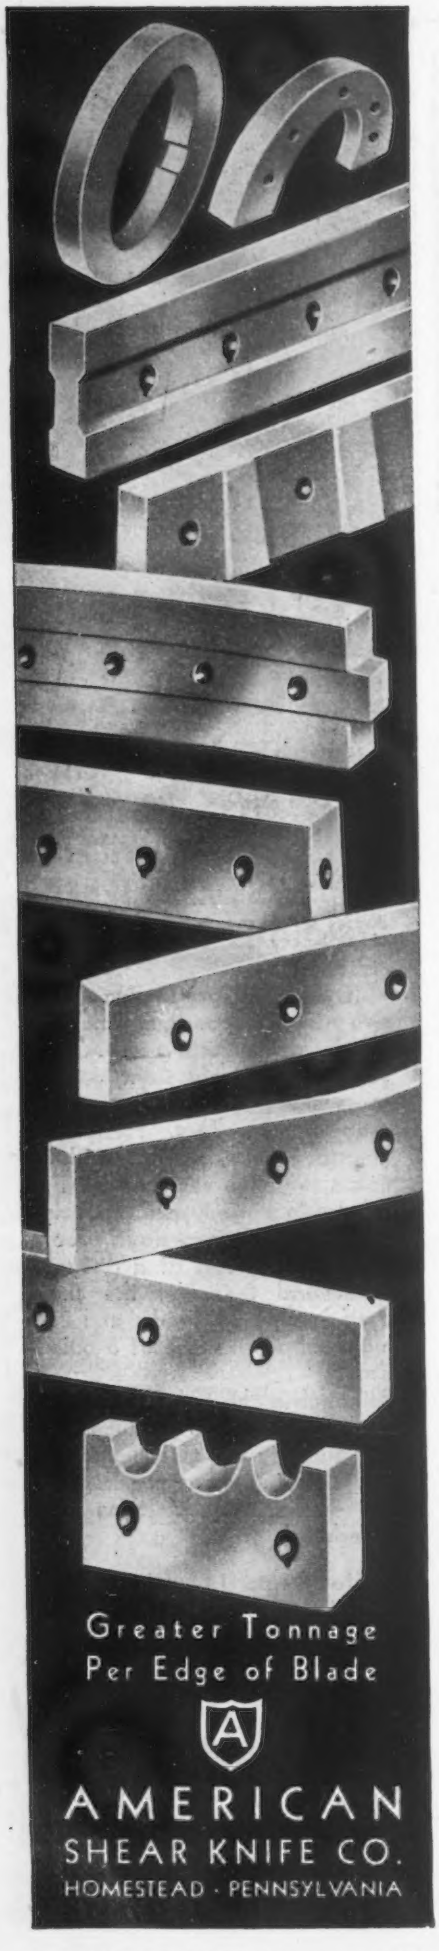
FOR "ROCKWELL" TESTING



Time Cycle for Procurement

• • • **Products** that were formerly shelf items are now critical components. Consequently, claimant agencies and prime contractors must take this into account, and orders must be far enough in advance so as not to delay production cycles or delivery, or not delay some other program by using AAA's or directives to obtain necessary materials. The following schedule, computed by WPB based on conditions as of Nov. 1, 1943, shows the time lapse, between normal ordering and delivery of various components. This time lapse includes time for engineering, procurement of materials and components, and field erection or installation, but excludes manufacturers' backlogs.

I Industrial Machinery and Equipment

Component	Total Weeks
Air & Gas Compressors	
1—Over 300 h.p.	28
2—15 h.p. to 300 h.p.	16
3—Below 15 h.p.	10
4—Portable	4
High Pressure Blowers	
1—Multi-stage	
a. Large	45
b. Small	32
c. Blast furnace	65
2—Single stage—under 50 h.p.	15
3—Single stage—over 50 h.p.	23
4—Rotary type	15
5—Positive displacement	21
Fans	
1—Heavy duty critical	19
2—All others	9
Material Handling Equipment	
1—Conveyor systems	19 to 39
2—Mechanical power transmission	15 to 24
3—Gears & speed changers	18 to 35
4—Elevators—average size	18
5—Industrial trucks	
a. Gasoline	26
b. Electric	26
c. Hand	9
Heat Exchangers	
1—Shell & tube type—large, above 3000 sq. ft.	50
2—Shell & tube type—medium, 1500 sq. ft.	43
3—Shell & tube type—small, below 1000 sq. ft.	35
Pressure Vessels	
1—Drums	35
2—Simple fractionating towers	43
3—Simple fractionating towers (alloy lined)	50
4—Field erected pressure vessels	43
Motors & Controls	
1—Integral h.p. motors and generators—a.c. to 500 h.p.	23
2—Navy motors and generators—a.c. to 500 h.p.	27
3—Fractional h.p.	18 to 34
4—d.c. motors—1 to 500 h.p	23 to 31
5—Navy d.c.—1 to 500 h.p.	23 to 31
6—Motor controls	
a. Navy controls	25 to 36
b. Maritime controls	24 to 30
c. Special industrial controls	12 to 24
d. Standard industrial controls	8 to 12
7—Small air circuit breakers	8 to 12
Welding Equipment	
1—Resistance	13
2—Gas	6
3—Arc	
a. Electric drive	8
b. Gas drive	12
c. Diesel drive	16
4—Electroplating and anodizing	21
5—Welding rods and electrodes	12

II Diesel and Gasoline Engines

Component	Backlogs	Total Weeks
Crankshafts		
Small (up to 200 cu. in. engines)	22	11
Medium (201 to 500 in.)	25	12
Large (over 500 in.)	39	16
Camshafts		
Small & medium (under 500 in. engines)	17	11
Large (500 in. and over)	29	13
Friction Bearings (Flanged & sleeve type)	34	10
Diesel Fuel Injection Equipment		
Nozzle	30	6
Holder	30	10 to 13
Pump	30	10 to 13
Diesel Engines (Liquid Cooled)		
Up to 50 h.p.	26	13 to 17
51 to 100 h.p.	43	17
101 to 150 h.p.	37	17
Over 150 h.p.	47	26
Gasoline Engines (Liquid Cooled)		
Up to 50 h.p.	29	17
51 to 100 h.p.	29	17
101 to 150 h.p.	34	21
Over 150 h.p.	41	21
Gasoline Engines (Air Cooled)		
Up to 35 h.p.	21	6 to 10

III Ship Propulsion and Operating Machinery

Component	Backlogs	Total Weeks
Propulsion Turbines—Geared	95	40 to 35
Main Reduction Gears	95	45 to 38
Main Propulsion Turbine Electrics	75	48 to 42
Diesel Engines		
1—Heavy	64	25
2—Light		20
Reverse and Reduction Gears (Diesel and Gasoline Engines)		
0 to 250 h.p. engines	22	16
250 to 2700 h.p. engines		25
Steam Engines	30	22 to 16
Marine Boilers	45	20 to 18
Steering Gears	40	21 to 14
Speed Reduction Gears	32	12

*IV Tools**

Component	Material Procurement, Weeks	Total Weeks
Anti-Friction Bearings	23	35
Mechanics Hand Service Tools		
Adjustable wrenches	10	13 to 21
Socket wrenches	10	8 to 17
Monkey wrenches	10	13 to 21
Pliers (side cutting)	10	13 to 21
Metal Cutting Tools		
Thread chasers for die heads & collapsible taps	10	8 to 12
Precision Measuring Tools		
Micrometers	10	16
Internal Micrometers	10	14
Calipers, pocket slide	10	18
Planer gages	10	65
Thickness gages	10	17
Telescope gages	10	22
Precision levels	10	43
Parallels	10	13
Protractors	10	56
Solid squares	10	28
Steel rules	10	17
Calipers	10	13
Vernier gear tooth gages	10	26
V-blocks	10	53
Forging Hammers	14	21 to 26
Presses, Mech. & Hyd. (Metal working)	14	17 to 21
Extruding Machines (Metal)	14	26 to 30
Machine Tool Attachments & Fixtures		
Lathe chucks	10	13 to 17
Die heads	10	8 to 12
Collapsible taps	10	8 to 12
Machine Tools		
Surface broachers	10	17 to 22
Planers, dbl. housing	10	32
Thread milling machines	10	26
Thread grinders	10	22
Cylindrical grinders	10	17
Precision boring machines	10	30
Special & way drilling machines	10	30
Spur & helical gear shaping machines	10	22
Special machines	10	35 to 39

*Time required for placement of orders in advancement of completion date of project or end product—includes average backlog.

DPC Contract Awards

• • • **Defense Plant Corp.**, RFC subsidiary, has authorized the following contracts:

International Minerals & Chemical Corp., Chicago, to provide additional facilities at plants in Carlsbad, N. M., and Austin, Tex., at a cost in excess of $175,000, making a total commitment of more than $18,850,000.

Chrysler Corp., Detroit, to provide additional facilities at a plant in Detroit at a cost in excess of $2,000,000, making a total commitment of more than $4,450,000.

Wallington Tube Corp., Wallington, N. J., to provide additional facilities at a plant in Wallington at a cost in excess of $200,000, making a total commitment of more than $2,200,000.

Lakey Foundry & Machine Co., Muskegon, Mich., to provide additional equipment at a plant in Muskegon at a cost in excess of $30,000, making a total commitment of more than $750,000.

Monarch Machine Tool Co., Sidney, Ohio, to provide machinery and equipment at a plant in Sidney at a cost in excess of $630,000.

S. K. Wellman, Cleveland, to provide additional equipment at a plant in Cleveland, at a cost in excess of $300,000.

Williamette Iron & Steel Corp., Portland, to provide additional facilities at a plant in Portland at a cost in excess of $55,000, making a total commitment of more than $1,570,000.

Williamette Iron & Steel Corp., Portland, to provide additional facilities at a plant in Portland at a cost in excess of $120,000, making a total commitment of more than $300,000.

American Bosch Corp., Springfield, Mass., to provide plant facilities at Chicopee, Mass., at a cost in excess of $1,350,000.

The Baltimore Pure Rye Distilling Co., Baltimore, to provide additional facilities at a plant in Baltimore at a cost in excess of $315,000, making a total commitment of more than $385,000.

The War Department announced:

Authorization for construction of runways, taxiways and installation of permanent night lighting facilities at Gunter Field, Montgomery, Ala. The initial authorization is $500,000. Work will be supervised by the Mobile, Alabama District Office of the Corps of Engineers.

Authorization for construction of additional runways, taxiways and parking apron at Matagorda Island, Texas. The initial authorization is $500,000. Work will be supervised by the Galveston, Texas District Office of the Corps of Engineers.

Among the Week's Trade Notes

Formica Insulation Co., Cincinnati, manufacturers of laminated plastics, will increase its capacity between 20 and 25 per cent by installation of new treating equipment involving infra-red heating.

•

Electric Controller & Mfg. Co., Cleveland, has opened an office at 732 Barr Building, Washington 6. A. W. Hartman will be in charge.

•

Electro Plastic Processes, Chicago, has taken over the new process of metal plating on plastics, glass, etc., developed by Precision Paper Tube Co. Stronger unity of bond between metal and plastic is claimed for the new process.

•

Bay State Abrasive Products Co., Westboro, Mass., has adopted a new identification mark, consisting of the wording "Blue-Flash" plus a symbol of a lightning flash, for the complete line of Bay State abrasive products.

•

A. B. Farquahar Co., Ltd., York, Pa., announces that from Jan. 1 it will operate as a corporation under the laws of Pennsylvania and will be known as A. B. Farquahar Co.

•

Kropp Forge Co., Chicago, announces that Charles L. Foley has been appointed engineering sales representative for New York and adjacent territories.

•

H. K. Porter Co., Pittsburgh, has opened an enlarged New York office at 50 Church Street, New York. The office will serve as an export office and as an Eastern center for the company's entire line of locomotives, process equipment and pumps.

•

National Electric Welding Machine Co., Bay City, Mich., has purchased the Electric Steel Castings Co. of that city. Edward Smith has been appointed president of both firms; C. C. Keegan was named secretary-treasurer and general manager.

•

Titeflex Metal Hose Co., Newark, N. J., will hereafter be known as Titeflex, Inc.

•

Graham Transmissions, Inc., Milwaukee, has added five more sales engineering organizations as representatives. They are: Fitch Bosworth, 7816 Delmar Boulevard, St. Louis 5; Enterprise Agencies, Ltd., 1400 Stanley Street, Montreal; I. I. Solzman, Pasol Engineering Co., World-Herald Building, Omaha 2, Neb.; John L. Underwood C., 139 Edgewood Avenue, Atlanta 3; William J. Cottrell, 131 S. W. 4th Avenue at 9211, Portland, Ore.

•

North American Philips Co., Inc., Dobbs Ferry, N. Y., announces the purchase of Philips Metalix Corp., including grounds and factory at Mount Vernon, N. Y.

•

DeBardeleben Coal Corp., Birmingham, has notified the trade that effective April 1 the corporation will sell direct to the consumer the by-product coke produced at its 60-oven Holt, Ala., plant, instead of through a sales agency.

•

Victor Spencer, president of Pioneer Gold Mines, Ltd., has purchased the Vancouver, B. C., plant of Hamilton Bridge Western, Ltd.

•

Colonial Broach Co., Detroit, has opened district offices at 1217 Grant Building, Pittsburgh 19, and 1109 Fletcher Trust Building, Indianapolis 9.

•

Maryland Bolt & Nut Co., Mt. Washington, Baltimore, has been acquired by the American Chain & Cable Co., Inc., Bridgeport, Conn. No changes in policies or personnel are contemplated.

•

Allen-Bradley Co., Milwaukee, has appointed Rietze & Co., 1017 E. Broadway, Louisville 4, as its sales representative for the Allen-Bradley line of electric controlling apparatus.

•

Kent-Owens Machine Co., Toledo, has appointed the Satterlee Co., Minneapolis, as exclusive agents for its milling machines in this territory.

•

American Foundrymen's Association, northern Illinois and southern Wisconsin chapter, meeting at Rockford, Ill., on Feb. 8, will be addressed by A. J. Edgar, technical adviser of the Gray Iron Founders' Society.

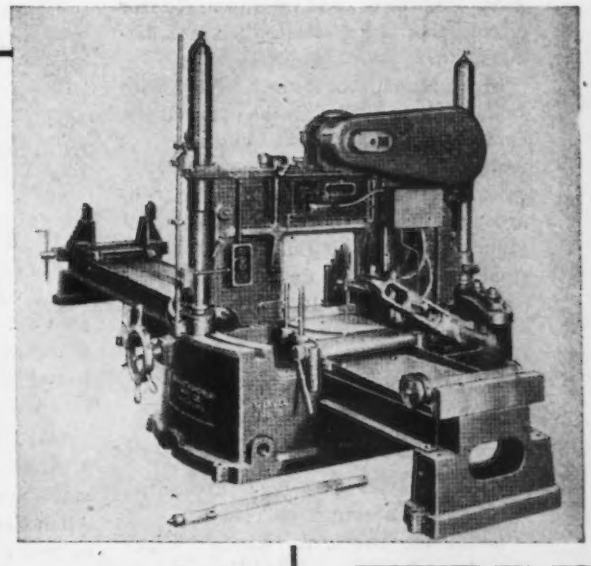
•

Cambridge Industrial Research organization, which controls the Arthur D. Little, Inc., laboratories, reelected all officers at its annual meeting. The company's officers are: Earl P. Stevenson, president; Raymond Stevens, Thorne L. Wheeler and Roger C. Griffin, vice-presidents; Henry G. Powning, treasurer; Frank N. Houghton, secretary, and Russell H. Stephens, comptroller.

•

The National Association of Fan Manufacturers meeting in Detroit, Jan. 19, elected the following officers for the ensuing year: C. T. Morse, president; J. M. Frank, vice-president, and L. O. Monroe, secretary-treasurer.

CUTS the Toughest Steels and Largest Sizes *easily.*



This giant hydraulic metal-cutting saw is more than just a larger hack saw. It is a new development in metal-cutting methods that introduces a new principle of metal sawing — the Roll-stroke blade action makes it possible to cut the toughest steels in the largest sizes easily and rapidly. It also permits a simple and efficient, very low pressure Hydraulic Feed System.

Built for heavy work, completely enclosed in heavy housing, this machine will stand up under the rough usage of the average steel mill warehouse and forge shop, where it will speed cutting-off, and reduce material loss.

MARVEL No. 18
Giant Hydraulic Hack Saw
Capacity 18"x18"
Cuts angles up to 45° by simply swiveling upper machine housing.

L. P. McALLISTER, JOSEPH G. ALTHOUSE and WILLIAM TAYLOR, left to right, have been appointed assistant to the general superintendent, metallurgical engineer and engineer of tests, respectively, of Lukens Steel Co.

PERSONALS

• **L. P. McAllister,** who has been metallurgical engineer for Lukens Steel Co., Coatesville, Pa., since 1936, has been appointed assistant to the general superintendent with specific duties of quality control. Also **Joseph G. Althouse** has been made metallurgical engineer, and **William Taylor** engineer of tests, succeeding Mr. Althouse.

Mr. McAllister has been with Lukens since 1922. He has served the company as assistant engineer of tests, engineer of tests, metallurgical sales engineer and metallurgical engineer. Mr. Althouse has been engineer of tests at Lukens since November, 1935. He first came to the company in July, 1917. Mr. Taylor entered the employ of Lukens as an apprentice metallurgist in September, 1936. In January, 1939, he became assistant engineer of tests.

• **R. H. Davies** has been appointed welding engineering representative in Washington, D. C., for Lincoln Electric Co., Cleveland. Mr. Davies has had wide experience in the industrial engineering field.

• **John M. Hodge** has been appointed development engineer, steel heat treating, of Carnegie-Illinois Steel Corp., Pittsburgh. He will represent the department of research and technology in the coordination and supervision of development work on heat treatment of steels and heavy forgings. Mr. Hodge has been with the corporation since 1933.

• **B. J. Brugge** has been appointed welding engineer in the Detroit office of the Lincoln Electric Co., Cleveland. Mr. Brugge, who has been associated with Lincoln since 1931, has served in the Los Angeles and Houston, Tex., offices and, until his transfer to Detroit, has been located in Washington, D. C.

• **B. M. Staley** has been appointed factory manager of Kaydon Engineering Corp., Muskegon, Mich. For the past 12 years, Mr. Staley has been with the rotary pump division of National Transit Pump & Machinery Co., Oil City, Pa.

• **Albert T. Taylor, Jr.,** has been made production manager for William Allen Son's Co., Worcester. For several years he was associated with Leland-Gifford Co. in production engineering work and prior to that was with the Morgan Construction Co. engineering department.

• **Thomas F. Wilson,** has recently been appointed assistant to senior vice-president **Frederick A. Stevenson** of American Car & Foundry Co. Also **E. J. Finkbeiner,** who has served in the operating department of the company since May, 1922, has been appointed assistant vice-president to Mr. Stevenson.

• **Richard W. Corns** has been appointed assistant general traffic manager of the B. F. Goodrich Co.

• **H. N. Arbuthnot,** formerly assistant general manager of sales of the Allegheny Ludlum Steel Corp., Brackenridge, Pa., has been appointed to fill the newly-created position of regional manager of the Detroit territory of the corporation, with headquarters at the Allegheny Ludlum plant and branch sales office in the Ferndale section of the city.

• **Stanley S. Weiser** of Gas Purifying Materials Co., Long Island City, N. Y., has been made assistant vice-president and purchasing agent for the company.

• **W. O. Franklin** formerly superintendent of the Radford division of Norfolk & Western Railway has been promoted to assistant to the general manager of the railway, and **S. J. Hale,** assistant superintendent of the division has been advanced to superintendent, succeeding Mr. Franklin.

• **Thomas P. Gorter** has been elected vice-president of Pullman - Standard Car Mfg. Co., Chicago. Since 1928 Mr. Gorter has been in charge of the company's Washington, D. C., car sales office and for the last two years he has been an assistant vice-president.

JOHN A. HAGAN and JAMES E. MOREHOUSE, left to right, have been made general manager and assistant general manager of the production planning department, Carnegie-Illinois Steel Corp. as announced in the Jan. 27 issue on page 96. At the same time HERBERT F. BYRNE has been made assistant to the general manager.

• **Lowell F. Whisler** has been made manager of purchases and expediting, and **Glenn R. Evans**, production manager for the Waukesha Motor Co., Waukesha, Wis. Mr. Whisler was with Haynes Automobile Co. and the Indiana Truck Co. before joining Waukesha Motors and Mr. Evans was with Fairbanks-Morse, Beloit, Wis., J. I. Case Co., Racine, Wis., and the General Refrigerating Co. previously.

• **Ralph R. Cheney**, manager of the lamp division of the Westinghouse Electric Co., Milwaukee division, for the last five years, has been appointed metropolitan manager in Chicago. He is Wisconsin chairman of the Illuminating Engineering society.

• **George J. Hubert** has been appointed manager of the newly created contract termination department of Mack Trucks, Inc. Mr. Hubert joined the Mack organization in 1917. In 1940 he went to Mack's Allentown, Pa.. plant to control inventories and act in other executive capacities.

• **D. I. Packard** has been appointed Chicago district manager of the Baldwin Locomotive Works, Philadelphia. He succeeds **Charles Riddell**, who after 61 years of service will continue with the Chicago office as special representative. Mr. Packard, prior to this appointment, served on the WPB assisting in arranging for the production of components for the locomotive construction program.

• **L. W. Schellhammer** has become affiliated with the Cincinnati sales office of the Inland Steel Co.

• **William G. Owens**, recently resigned from the local staff of the WPB after about a year's service, has resumed duties with the sales department of Wheeling Steel Corp., Wheeling, W. Va. He will be located at the general office and cover territory designated as the Columbus district. Also **Virgil C. Dollman** is transferring from the tubular sales division to the Cincinnati district office to cover sales territory to Indiana.

• **Enoch Perkins** has been elected vice-president of the Mutual Chemical Co. of America, Jersey City, in charge of the company's mining and ore department. Mr. Perkins has had wide mining experience. In recent years, in addition to supervising the company's mining operations in New Caledonia, he has visited the South African fields as well as the rich Turkish mines.

• **James Terry** has been appointed district manager of the Cincinnati sales office and warehouse of the Columbia Tool Steel Co. He will take the position which became vacant upon the recent death of **W. G. Sonderman.** Mr. Terry has been connected with the company for several years and now fills the position held for over 26 years by his father, **F. A. Terry**, now retired.

• **Henry Ford II**, already a director of the Ford Motor Co., has been elected a vice-president. He will devote his attention to merchandising and sales, as did his father, the late **Edsel Ford.**

• **F. A. Burley** has been appointed purchasing agent of Link Aviation Devices, Inc.

• **Francis J. Byrne** has retired as assistant director of the Du Pont public relations department, with which he has been associated for 27 years. He has reached the retirement age of 65 years.

Mr. Byrne went to the Du Pont company in February, 1916, when the publicity bureau was established.

• **George E. Westerholm** has been appointed an abrasive engineer for the Milwaukee territory by the Norton Co., Worcester, Mass., where he will assist **F. W. Grant.**

• **James A. Dwyer** has been appointed general manager of sales and branches of Crane Co. with headquarters in Chicago. Mr. Dwyer joined the Crane organization in 1917.

• **Burt W. Wetherbee**, research manager of Globe Woven Belting Co., Buffalo, has been appointed manager of technical services of American Resinous Chemicals Corp., Peabody, Mass.

J. L. WOOD, assistant vice-president, American Car & Foundry Co.

• **J. L. Wood,** since December, 1936, mechanical engineer of American Car & Foundry Co., New York, has recently been appointed assistant vice-president. Mr. Wood has served the company for 38 years, beginning his association in 1906 in an engineering capacity. In 1928 he transferred to the New York office as assistant mechanical engineer in the engineering department, and in 1936 was appointed mechanical engineer.

• **Michael B. Dwyer,** district sales manager in charge of the St. Louis office of the Pennsylvania Salt Mfg. Co., Philadelphia, has retired from active duty with the company.

• **W. Wallace Kellet** has recently resigned as chairman of the board of Republic Aviation Corp., in order to devote his efforts more fully to the affairs of Kellett Aircraft Corp., of which he is president. Mr. Kellett became associated with the present Republic company in November, 1933, as a member of the board and executive vice-president. Re-organizing the company which had less than 200 employees, he was elected president in June, 1939. He continued as president until May 1, 1941, when **Ralph S. Damon** became president and Mr. Kellett was elected chairman of the board.

• **Jean A. Hollander** has been named director of consumer information of the Can Manufacturers Institute, Inc.

• **James N. Morrell** has been made sales manager of limitorque valve control division of Philadelphia Gear Works, Philadelphia, and **Thomas V. Withington** relinquished his position as chief engineer to become assistant sales manager of the limitorque division. **William F. Plume** succeeded Mr. Withington as chief engineer, and **Robert E. Richards** has been appointed assistant chief engineer.

• **Paul W. Polk,** vice-president of the Sheffield Corp., Dayton, Ohio, has been granted a leave of absence to accept a commission as lieutenant in the Navy.

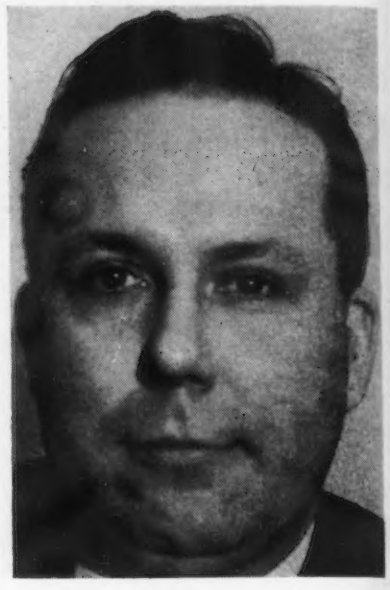
• **John F. Hazen,** for the last 16 years manager of sales of the wire and wire products division of Bethlehem Steel Co., recently retired from active service, because of illness. He is succeeded by **Ralph E. Sharp,** who for several years has served as his assistant.

• **F. W. Wells,** former assistant to the vice-president in charge of production for the J. I. Case Co., Racine, Wis., has accepted a position with A. O. Smith Corp., Milwaukee, where he will be on the staff of President, W. C. Heath.

• **H. R. Loxterman** has been appointed engineer in charge of sales of Blaw-Knox furnace equipment throughout the Middle West. His office will be in Chicago. Mr. Loxterman has been in charge of similar work in the Pittsburgh district and is a graduate of Carnegie Institute of Technology.

• **William J. Massey** has been appointed general lamp sales manager of the Westinghouse lamp division with headquarters at Bloomfield, N. J. In his new position, Mr. Massey will have charge of all lamp sales activities of the lamp division including district sales offices; the illuminating engineering, commercial engineering and advertising departments.

• **Dr. Charles A. Getz,** director of the research division of Cardox Corp., Chicago, has been elected to fill the newly created position of vice-president in charge of research of that company.



CARL L. ZAK has been appointed manager of tubular sales for Pittsburgh Steel Co., as announced in the Jan. 27 issue, page 137.

• **W. M. Stearns,** manager of trade relations and special contracts, General Electric Co., Schenectady, N. Y., retired recently after 39 years of service. Mr. Stearns will be succeeded by **W. A. Sredenschek,** who for the past three years has been assistant manager of trade relations and special contracts. In 1904 Mr. Stearns entered the service of the Fort Wayne Electric Works, a General Electric constituent company which later became a main apparatus plant of G.E. The following year he became manager of the Fort Wayne company's Atlanta, Ga., office, serving in this capacity until 1909. After holding several supervisory positions he was named, in 1927, manager of special contracts in the commercial general department. In 1940 he was appointed to his present position.

• **Noel Poux,** who has been in charge of the plastic research department of Talon, Inc., Meadville, Pa., for several years, has been advanced as manager of the works engineering division of all Talon plants. **C. C. Judd,** formerly manager of the Erie plant, has been promoted to production manager of all slide fastener manufacturing both at Erie and Meadville. **D. Case** has been promoted to general superintendent in charge of the Erie plant, and **M. S. Ramsey** has been promoted to production superintendent, in charge of plant 5, Meadville, slide fastener operations.

• **Howard A. Flogaus** has been elected vice-president in charge of engineering for the J. G. Brill Co., Philadelphia. Mr. Flogaus, who has been with the company approximately five years as chief engineer, has been identified with the motor coach industry since 1924.

• **Robert R. Hirsch** of Bunting Brass & Bronze Co., Toledo, Ohio, has been made director of sales, succeeding **George H. Adams**, recently named executive vice-president of the company.

• **Albert W. Hendrickson** has been appointed director of employee services, in charge of employment and personnel activities, at Farrel-Birmingham Co.'s three plants at Ansonia and Derby, Conn., and Buffalo, N. Y.

• **H. M. Comstock**, for more than 15 years director of sales for the Simplex Products Corp., Cleveland, has been made engineering sales representative of Kropp Forge Co. and Kropp Forge Aviation Co., for the Southern California territory.

• **H. B. Lilley**, formerly assistant chief inspection engineer, has been promoted by the steel and tube division of the Timken Roller Bearing Co., Canton, Ohio, to the position of sales development engineer. He will specialize in the application of mechanical tubing to machine tool products and other engineering applications.

• **Baird Tewksbury, Jr.**, formerly attached to the Houston office of the Jones & Laughlin Steel Corp., in sales work, has been transferred to the Philadelphia office.

OBITUARY...

• **William J. O'Connor**, director of contracts and counsel for the frontier division of Bell Aircraft Corp., died Jan. 20, in Buffalo General Hospital. He was 45 years old.

• **Paul Niegsch**, for more than 31 years a member of the Pemco Corp., died suddenly of a heart attack on Dec. 14.

• **Harvey Hanes**, chief technician of the experimental department of Remington Rand, Inc., died January 21 at his home in Tonawanda, N. Y.

• **David W. Rodger**, vice-president, secretary and sales director of Federal Mogul Corp., Detroit, died Jan. 4. He was president of the National Standard Parts Assn. in 1934-35.

• **Laurence A. Nye**, Buffalo district engineer and sales representative of the Sterling Grinding Wheel Co., Tiffin, Ohio, died January 21 at his home in Snyder, N. Y. He was 58 years of age.

• **Alfred A. Ziegler**, retired manufacturer of railroad signals, died Jan. 17 in Milton, Mass. Born in Switzerland 79 years ago, he came to Boston as a boy and attended Massachusetts Institute of Technology.

• **Arthur H. D. Altree**, vice-president in charge of sales of the American Bosch Corp. until he retired in 1930, died recently. He was born in Manchester, England, 77 years ago.

• **Alfred V. Sims**, University of Pennsylvania graduate and manufacturer of pumps and valves, died at Hamden, Conn., Jan. 21. He was 80 years old.

• **Lyle H. Olson**, outstanding appraisal expert, vice-president and executive committee chairman of the American Appraisal Co., Milwaukee, died recently at his home in New Rochelle, N. Y. He was one of the organizers of the firm and in 1920 moved to New York to supervise the firms' eastern operations and foreign business.

• **Allan E. Hall**, well-known mill machinery authority, manager of the milling machinery department at Allis-Chalmers, Milwaukee, for more than 20 years, died at a hospital there Jan. 17 at the age of 70 after several months' illness. He came with Allis-Chalmers in 1909 with the Seattle district office. He formerly was president of the Cereal Machinery Assn. and of the Multiple V-Belt Drive Assn.

• **Allen N. Bradford**, general manager of the Russell, Burdsall & Ward Bolt & Nut Co. plant at Rock Falls, Ill., died late in December at Sterling public hospital following a few days' illness. Mr. Bradford, a nationally known figure in the industry, had been associated with the bolt and nut business practically all his life.

• **Maxwell R. Berry**, founder and president - treasurer of the Electric Products Co., recently died after a brief illness in a Jacksonville, Fla., hospital.

• **Frank H. Whelden**, 75, secretary of the Detroit Star Grinding Wheel Co., died recently.

• **Mason P. Rumney**, vice-president and director of Detroit Steel Products Co. for 18 years, died recently.

• **John G. Mattes**, organizer and former president of the Standard Sheet Metal Works, Milwaukee, died Jan. 7 in a hospital at Beaver Dam, Wis., where he had lived since his retirement three years ago. He was 78 years old.

• **Edward J. Frost**, founder and president of the Frost Gear & Forge Co., Jackson, until 1939, died recently after a long illness. He was a past president of the American Gear Manufacturers Assn. and the Drop Forge Assn.

• **Lawrence H. Dunham**, assistant manager of the metallurgical department of the American Steel & Wire Co., died suddenly in Pittsburgh, Jan. 19. Mr. Dunham was born in Chicago, Ill., in 1891. He began working for the American Steel & Wire Co. in December, 1916. Mr. Dunham was made assistant manager of the metallurgical department in April, 1942.

• **Alfred Fritzsche**, vice-president in charge of sales of Automatic Sprinkler Corp. of America, died in New York City on Jan. 18 after a long illness. Mr. Fritzsche was 74 years of age and had spent his entire business life in the sprinkler industry.

• **Ernest L. Brandt**, managing secretary of the Engineering Society of Detroit and secretary of the Michigan Engineering Society died recently. He had been active in engineering circles in Michigan for 20 years.

Cleveland Automatic Converts for Clark Job

Cleveland

• • • **Typical of the steps** machine tool builders are taking to maintain shop volume in the face of failing orders and reduced backlogs is the subcontract now in progress in the converted plant of Cleveland Automatic Machine Co. here. The contract which first came through last August amounts to about $10 million and entails the complete construction and assembly of roughly 3000 Clark Utilitrucks under a patent-free arrangement for the Army and Navy.

To accommodate the construction of these gasoline driven utility trucks Cleveland Automatic was required to reconvert nearly its entire shop. The reconversion required few new tools but meant rearrangement of the shop. This was complicated by the necessity of maintaining partial capacity to produce Cleveland die casters and automatics while arranging a production and assembly line for the new truck contract. Conversion was mainly completed by mid-December and parts are now flowing toward the nearly completed assembly line. Delivery of the first truck is expected about Feb. 1.

Many complications have impeded the production of the product to date including the necessity for redesigning certain parts not obtainable from former Clark suppliers, the necessity for building a large number of jigs and fixtures and copying Clark patterns to insure complete interchangeability of parts.

Illustrating also the complex network of contracts behind each prime product, Cleveland Automatic estimates that in addition to being a subcontractor itself some 33 per cent of its contract has been sub-let.

WPB Gives Chicago Pneumatic Probation Reprieve on CMP

Washington

• • • **The Chicago Pneumatic** Tool Co., New York, was put on probation Jan. 26 until April 1 after assuring the WPB that it will comply with all WPB orders, including CMP regulations. The probationary order resulted from a hearing on WPB charges that the company had violated controlled materials plan regulations in its Detroit, Cleveland and Franklin, Pa., plants.

According to the WPB, the violations included acceptance of deliveries of materials in violation of CMP inventory regulations and failure to maintain records of CMP allotments.

•

Foote Brothers Report for 1943

Chicago

• • • **In the annual report** for the fiscal year ended Oct. 31, 1943, Foote Bros. Gear & Machine Corp. reports net income of $858,303 after all charges including a reserve of $750,000 against possible refund of profits through renegotiation of war contracts. It compares with net income for the previous fiscal year of $686,114 after renegotiation refunds.

Net sales for the last fiscal year amounted to $26,284,943 compared with $18,368,180 for the previous year. Because of contract price reductions in the current year which cut dollar sales for 1943 by an aggregate of approximately $5,500,000, the sales figures for last year do not fully reflect the increase in production over the 1942 fiscal year, W. A. Barr, president, stated.

All facilities to be furnished by the government, totaling approximately $12,000,000, have now been constructed or acquired. The company has made arrangements for a regulation "V" loan of $5,000,000 which replaces a loan agreement under which borrowings to date have amounted to $2,000,000.

Employees now number 6400 as compared with 2800 a year ago.

60,000 R.P.M. MOTOR FOR MACHINE TOOL INDUSTRY—*This super-fast motor designed by Westinghouse engineers, is used for grinding, polishing and routing metals. Formerly the high speeds necessary for these applications were obtained through use of belts and pulleys. The new motor is induction type and is supplied with power from a 1000-cycle generator. The rotor that turns at 60,000 r.p.m. is 1¾ in. in diameter by 2 in. long. Centrifugal stresses at the surface reach about 15,000 lb. per sq. in.*

National Machinery to Build Manville Cold Headers

Tiffin, Ohio

• • • **Movement of drawings** and patterns of the E. J. Manville Machine Co., Waterbury, Conn., to the National Machinery Co., Tiffin, Ohio, is now in progress, but the E. J. Manville Division of National will not begin operations for several months. National acquired the Waterbury concern last November and will produce Manville cold headers and thread rolling machinery under the Manville brand name. None of the machinery is being transferred and National will not operate the Waterbury plant. National produces upset forging machines and bolt making equipment.

•

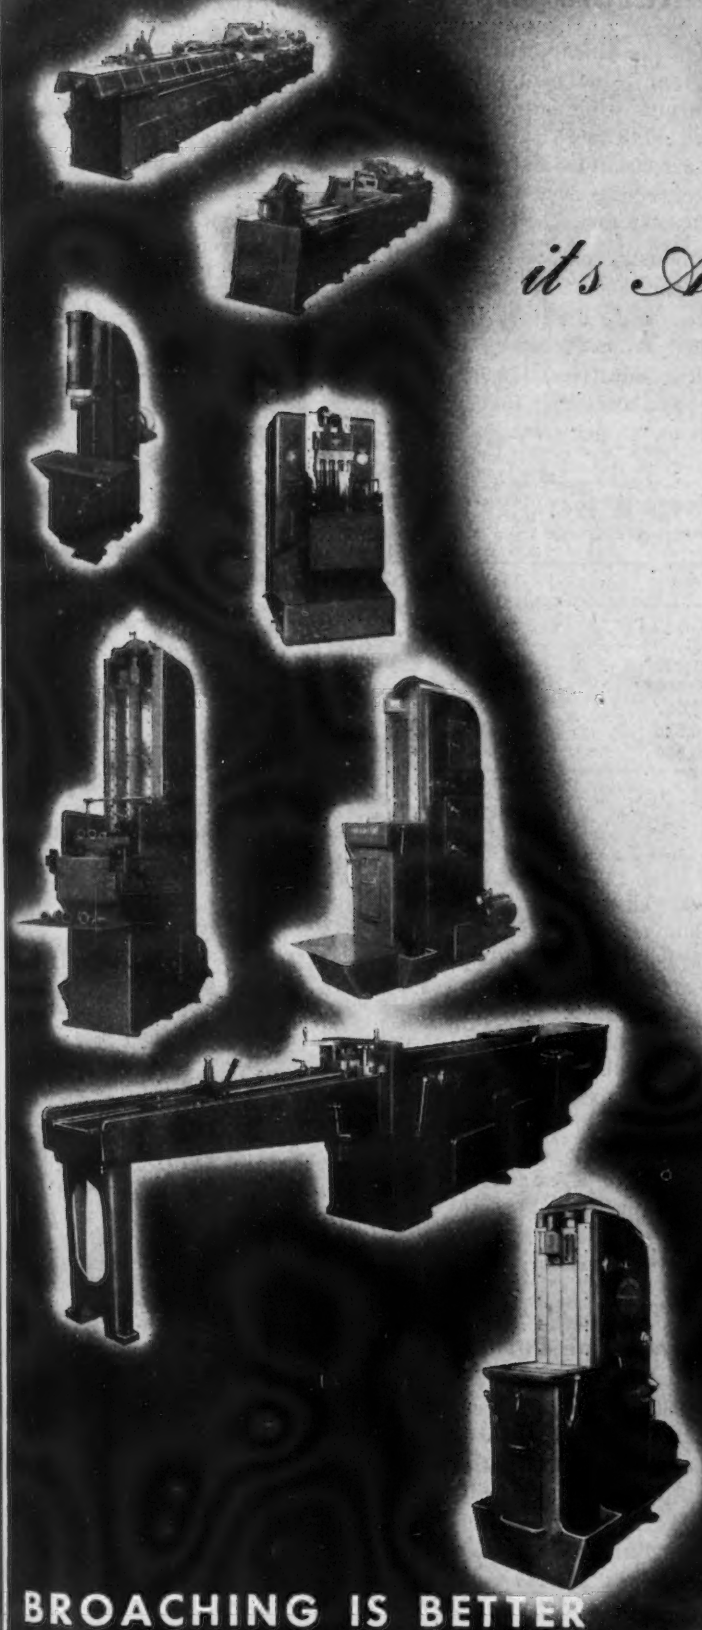
Layoffs Held to Minimum

Cincinnati

• • • **The downward curve** in production of machine tools continues, although some slack in the manufacturing tempo has been eased by conversion to other production and to jobbing contracts. So far, there has not been a sufficient amount of this to take up all the slack. At the same time, manufacturers are loathe to release plant personnel because of hope for improvement in the situation as the year progresses, and accordingly, layoffs are being held to a practicable minimum. Outlook for the industry in this area appears to be optimistic from reports of manufacturers of inquiries that they have received from other industries contemplating reconversion.

THIS AIRCRAFT ENGINE PLANT NOMINATES

it's All-American Team



So high is the production-with-precision obtained by broaching that one machine is ample for most metal working plants. Few have as many as 10 or 15.

Consider, therefore, the importance of this particular aircraft engine plant in the broaching picture, with 91 American machines!

Their personnel *knows* broaching. They know the value of dealing with an old-line company whose principals have been identified with broaching since the turn of the century. They know, too, the importance of a *complete* broaching service—machines, tools, and engineering — for winning war production, profitable post-war production.

Significant is this overwhelming vote of confidence in American Broach equipment.

Bauxite Output in 1943 Sets Record

• • • **Estimates of bauxite** mine production totaled 7,026,040 net tons, more than double 1942's record output of 2,966,221 tons. Data on imports of foreign ore are not available for publication, but imports reached a new all-time record, more than 60 per cent greater than in 1942. Domestic production and imports in 1944 are expected to be considerably less than in 1943 owing to the recent cutback in alumina and aluminum production announced by WPB and to the large stockpiles of bauxite held both by Metals Reserve and private industry.

Production of low-silica bauxite, containing less than 8 per cent SiO_2, totaled 2,329,600 tons while output of high-silica restricted, 8 to 15 per cent SiO_2, reached 4,228,000 tons and non-restricted ore, containing over 15 per cent SiO_2, was 468,440 tons.

The alumina industry used 4, 771,-000 tons or 89.3 per cent of the total, while the abrasive and refractory industries consumed 347,000 tons or 6.5 per cent, chemical industries, 179,900 tons or 3.4 per cent, and other industries 42,100 tons or 0.8 per cent.

Bauxite Output, Shipments and Consumption, 1939 to 1943
in net tons, dried equivalent

From: U. S. Bureau of Mines

Year	Mine Production	Shipments from mines	Consumption	Total Stocks end of year
1939	436,792	420,344	971,000*	**
1940	486,789	491,493	1,200,600*	**
1941	1,049,496	1,001,475	1,928,052	776,231
1942	2,966,221	2,768,343	2,820,525	1,759,597

Collapsible Tubes to be Made

• • • **Plans for resumption** of the manufacture of aluminum collapsible tubes for a wide variety of civilian and military needs, have been announced by Aluminum Co. of America. The release of aluminum for collapsible tubes has been made possible through stepped-up aluminum production, which has now reached a point where there is a growing surplus over and above all military needs.

Conservation order M-115, recently signed in Washington, lists the following products which may now be packaged in aluminum tubes—Ointments and other preparations for ophthalmic use, sulfa drugs in ointment or jelly form, diagnostic extracts—allergens,—morphine for individual dose hypodermic injection, sold directly to the Army or Navy, preparations for introduction into the body orifices, and dental cleansing preparations. Shaving cream is not included in the present order.

The speed of resumption of the manufacture of aluminum collapsible tubes at Alcoa's Edgewater, N. J., works and the blanks which the company will supply to other manufacturers for the making of aluminum tubes, will be determined by the amount of competent help which can be obtained without diverting manpower from essential war production.

Customers are asked to cooperate by holding their immediate demands for aluminum tubes to a minimum and by placing their orders subject to mill schedules determined by the needs of the war program.

•

Canadian Mineral Value Down

• • • **Production in minerals** in Canada during 1943 of an estimated value of $524,426,850 showed a decrease of $42,800,000 for 1942, largely due to reduced output of gold, according to report by the Canadian Bureau of Statistics. The Bureau estimated the value of metals as a group at $357,269,458, down 9 per cent from the year immediately preceding.

The combined value of copper, nickel, lead and zinc in 1943 was $180,271,613, 7.6 per cent more than in 1942.

Another group of strategic metals, including antimony, bismuth, cadmium, chromite, cobalt, magnesium, molybdenite, tin and tungsten, reached $7,079,350 as compared with $4, 338,808 in the previous year.

Others, including arsenic, iron ore, mercury, selenium, tellurium and titanium ore, increased in value to $8,059,002 from $6,132,674.

•

MRC Purchases Be Cu Scrap

• • • **Because beryllium** copper scrap is overcrowding generators' plant facilities, the Metals Reserve Co., through Clifton Products, Inc., Painesville, Ohio, has arranged to purchase such scrap from generators only. These purchases, it was emphasized, will in no way interfere with normal purchases by the producers and approved smelters mentioned in general preference order M-160-a.

Metals Reserve will purchase beryllium copper scrap in accordance with the following price schedule, with freight collect, subject to weighing, grading and analyzing by Clifton Products, Inc.

	Per Lb. Alloy, Wr'ght	Per Lb. Alloy, F'dry	Be Contained Wr'ght	Be Contained F'dry
2 Per Cent Be Content (Cu A 9C*)

*To be corrected to market or OPA ceiling.

Definition of terms used on the attached price schedule.

Grade 1 (uncontaminated): Free of all contamination other than organic matter, corrected to clean weight.

Grade 2: Containing less than 2 per cent of metallic contaminants, including iron, corrected to Be Cu—clean weight.

Grade 3: (A) borings and turnings containing less than 2 per cent of metallic contaminants, including iron, aluminum and aluminum copper.

(B) Punchings and punched strip. Metallic coated or containing less than 15 per cent of all contaminants. Both corrected to beryllium copper—clean weight.

Grade 4: Must have at least 70 per cent distinguishable beryllium copper content.

SCRAP

. . . News and Market Activities

Alloy Scrap Shipments Decline Mills Buying on Monthly Basis

New York

• • • **Major changes** in the scrap market during the past few weeks have been a tightening up of mills in accepting alloy scrap either mixed or segregated, and closer buying controls. U. S. steel led the field with regard to alloy scrap acceptances by notifying dealers that such shipments were not wanted. Several mills, however, have started buying all types of scrap on a month to month basis, or on 30 to 60-day commitments.

This general trend reflects the continually easing situation with regard to scrap supplies. In many areas, some types of scrap cannot be sold at ceiling prices, and on the West Coast it is reported that melting scrap is bringing $1 to $2 under the ceiling. Plans are being made in that area to ship some of this scrap, mainly from shipyards, back to mills in the Middle West while mills on the coast prefer not to have the material moved out of the district, supplies are accumulating faster than they can be used and mills are unwilling to accept scrap that will make their inventories too large.

Many mills, especially in the western Pennsylvania-eastern Ohio area, have been out of the scrap market completely and are expected to remain out for several weeks to come. This, of course, indicates that stocks are sufficiently large to obviate any necessity for purchased scrap. Supplemented by the constantly recurring home scrap, the current mill stocks are sufficient for current high production rates.

•

PITTSBURGH — Dealers could sell more scrap here if it was available, but there is no extreme shortage at any location. Demand and supply are fairly well balanced, and the lack of tight spots is probably due to the open winter weather.

•

BUFFALO—Scrap receipts were light this week while demand held fairly steady. All items were reported moving but specialties slumped, electric furnaces appearing to be well supplied. District scrap contracts now are being based on 60 and 30-day termination clauses, with unshipped tonnage at the end of each contract period subject to cancellation.

•

CLEVELAND — For the past week largest buyers have remained out of the market locally. Blast furnace demand has fallen off after light buying. Supplies, while small, appear to be sufficient in all grades except cast. Buying is expected to be conducted on a month to month basis for the balance of the year. Local buying is expected to resume toward the middle of February.

•

CINCINNATI—The district scrap market appears well balanced, with consumers showing more interest in taking material. A special improvement in open hearth scrap has been noted, although cast material continues to be sought after by foundries. Alloy items continue to be a surplus on the market. Some of the current buying interest is believed to be stimulated by reports of tightness in other areas, particularly in the east for scrap and local consumers are moving to prevent a pinch to them here.

•

BOSTON—A further drop in supplies of metal working shop scrap emphasizes the quietness of business. The 3000 tons of American Steel & Wire Co., Worcester, scrap was taken by General Scrap. The Worcester mill has bought 100 tons of street car rails from Chicopee at $15.90 a ton f.o.b., or 90c. more than WPB offered for the rails. The WPB has requisitioned a 500-ton state bridge in central Massachusetts.

•

BIRMINGHAM—The scrap market here remains extremely dull and if there is any change in the trend so far as demand is concerned it is downward. There is little movement of material either to dealers' yards or to mills.

•

PHILADELPHIA — Demand for open hearth grades continues high. Several mills here are anxious to build up inventories. WPB's attempt to solve the alloy scrap problem is having little effect since mills have refused to accept the alloys for use in open hearths. U. S. Steel has even notified suppliers that it will not accept alloy scrap whether mixed or segregated. Railroads would like to ask for bids for their scrap rather than the present method of allocation of railroad scrap. Mixed ferrous and non-ferrous scrap was sold by the Navy Yard last week to Max Bailis & Sons at $14.89.

•

NEW YORK—No changes can be noted here. Open hearth grades are readily moved while low phos demand continues to be weak. Turnings containing nickel from Wright Aeronautical have been sold at machine shop turnings price.

Steel mills are well supplied with scrap. Several companies report additions to stock piles during January. Commitments by mills do not extend beyond a month or six weeks.

Better Scrap Segregation Urged

•**COLUMBIA STEEL CO.'S** *drive to improve scrap segregation resulted in these photos of the "good" and "bad" examples. The "bad" shown above, slows charge, impedes production and contaminates heats.*

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles; No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing points (cents per gross ton) are: Pittsburgh, Brackenridge, 55c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, 42c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Harrisburg, Phoenixville, Bethlehem, Kokomo, Duluth, St. Louis, 28c.; Buffalo, Claymont, 36c.; Conshohocken, 11c.; Atlanta, Birmingham, 32c.; Pittsburg, Cal., 42c.; Middletown, 14c.; Sparrow's Point, 11c.; Chicago, 84c.; Detroit, 53c.; Alabama City, 26c.; Minnequa, 22c.; Seattle, 38c. At Cincinnati, for basic open hearth grades, foundry steel and auto springs and crankshafts, deduct 80c. per ton.

PITTSBURGH basing point includes switching districts of Bessemer, Homestead, Duquesne, Munhall and McKeesport, Cincinnati basing point includes Newport, Ky., switching district. St. Louis includes switching districts of Granite City, East St. Louis, Madison, Ill. San Francisco includes switching districts of S. San Francisco, Niles and Oakmont, Cal. Claymont, Del., includes the switching point of Chester, Pa. Chicago includes Gary, Ind., switching district.

MAXIMUM SHIPPING POINT PRICE—Where shipment is by rail or vessel, or by combination of rail and vessel, the scrap is at its shipping point when placed f.o.b. railroad or f.a.s. vessel. In such cases, the maximum shipping point prices shall be: (a) For shipping points located within a basing point, the price listed in the table above for the scrap at the basing point in which the shipping point is located, minus the lowest established switching charge for scrap within the basing point and (b) for shipping points located outside the basing point, the price in table above at the most favorable basing point minus the lowest transportation charge by rail or water or combination thereof. In lieu of dock charge add 75c. a ton, but 50c. if moved by deck scow or railroad lighter. Shipping by motor vehicle: The scrap is at its shipping point when loaded. For shipping points located within basing points take price listed in table minus applicable switching charge. If located outside a basing point, the price at the most favorable basing point minus lowest established charge for transporting by common carrier. If no established transportation rate exists, the customary costs are deducted. Published dock charges prevail. If unpublished include 75c.; at Memphis, 50c.; Great Lakes ports, $1; New England, $1.25. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding grade or grades of prepared scrap. In no case, however, shall electric furnace and foundry grades be used as the "corresponding grade or grades of prepared scrap." Converter may charge $2.50 per ton on consumer-owned unprepared remote scrap (see order). A preparation-in-transit charge for allocated unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced—$2; 75 to 85% Fe—$4; under 75% Fe—$8 per ton. Mill scale of 65% or more Fe—$8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1 per cent oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5 per cent oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c.

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto, Ohio; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.; Sheffield Steel Corp. $2.55 St. Louis.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo, Colo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—Sheffield Steel Corp. $2.75 St. Louis; W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery in U. S. except Texas and Oklahoma may use Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. when shipped outside Alabama, Mississippi, Louisiana, Georgia, Florida, Tennessee, Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base granted on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base granted on Kokomo, Ind., product; Superior Sheet Steel Co. granted Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1999 lb.; strip, extras on all quantities; bars, 1500 to 39,999 lb.; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 to 39,999 lb. (15) 1000 to 39,999 lb. (16) 1500 to 39,999 lb. (17) 2000 to 39,999 lb. (18) 3500 to 39,999 lb.

(*a*) Philadelphia: Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

CAST IRON WATER PIPE

Per Net Ton

6-in. and larger, del'd Chicago.... $54.80
6-in. and larger, del'd New York... 52.20
6-in. and larger, Birmingham 46.00
6-in. and larger f.o.b. cars, San Francisco or Los Angeles 69.40
6-in. and larger f.o.b. cars, Seattle. 71.20

Class "A" and gas pipe, $3 extra; 4-in. pipe is $3 a ton above 6-in. Prices shown are for lots of less than 200 tons. For 200 tons or over, 6-in. and larger is $45 at Birmingham and $53.80 delivered Chicago, $59.40 at San Francisco and Los Angeles, and $70.20 at Seattle. Delivered prices do not reflect new 3 per cent tax on freight rates.

LAKE SUPERIOR ORES

(51.50% *Fe, Natural Content, Delivered Lower Lake Ports**)

Per Gross Ton

Old range, bessemer, 51.50 ..... $4.75
Old range, non-bessemer, 51.50..... 4.60
Mesaba, bessemer, 51.50 ..... 4.60
Mesaba, non-bessemer, 51.50 ..... 4.45
High phosphorus, 51.50 ..... 4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

SEMI-FINISHED STEEL

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Steel

Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton	54.00

Shell Steel

	Per Gross Ton
3 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleveland, Youngstown and Birmingham.

Prices delivered Detroit are $2.00 higher; E. Michigan, $3 higher.

Note: The above base prices apply on lots of 1000 tons of a size and section to which are to be added extras for chemical requirements, cutting, or quantity.

Sheet Bars

Pittsburgh, Chicago, Cleveland, Youngstown, Buffalo, Canton, Sparrows Point, Md.

	Per Gross Ton
Open hearth or bessemer	$34.00

Skelp

Pittsburgh, Chicago, Youngstown, Coatesville, Pa., Sparrows Point, Md.

	Per Lb.
Grooved, universal and sheared	1.90c.

Wire Rods

(No. 5 to 9/32 in.)

	Per Lb.
Pittsburgh, Chicago, Cleveland	2.00c.
Worcester, Mass.	2.10c.
Birmingham	2.00c.
San Francisco	2.50c.
Galveston	2.25c.

9/32 in. to 47/64 in., 0.15c. a lb. higher. Quantity extras apply.

TOOL STEEL

(F.o.b. Pittsburgh, Bethlehem, Syracuse)

	Base per lb.
High speed	67c.
Straight molybdenum	54c.
Tungsten-molybdenum	57½c.
High-carbon-chromium	43c.
Oil hardening	24c.
Special carbon	22c.
Extra carbon	18c.
Regular carbon	14c.

Warehouse prices east of Mississippi are 2c. a lb. higher; west of Mississippi 3c. higher.

Chromium-Nickel Clad Steel (20%)

	No. 304
Plates	18.00c.*
Sheets	19.00c.

*Includes annealing and pickling.

WE'RE SEEKING

JUST THE RIGHT MAN TO HIRE AS

SUPERINTENDENT

One of the leading and long established small arms manufacturers of America wants a plant superintendent of outstanding ability. We are looking for a man who will strengthen our organization and play a major part in our post-war operation for which we contemplate a permanent personnel of approximately one thousand workers. Our plant is located in New England.

The man we want must have the experience, background, and proved ability for this highly important position, for which we will gladly pay an ample and commensurate salary.

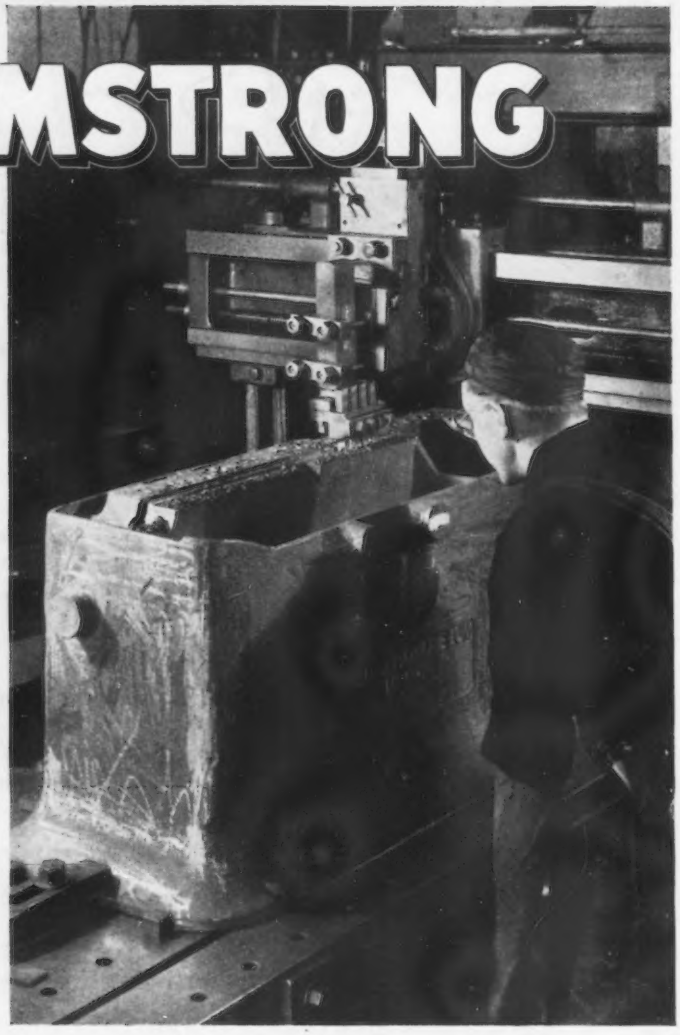
In applying, state in detail your experiences, education, age, condition of health and other points we ought to know about you. Please include references and, if convenient, your photograph. All applications will be considered as strictly confidential.

APPLY BY LETTER ONLY

ADDRESS BOX B-166

Care *The Iron Age*, 100 E. 42nd St., New York 17

ARMSTRONG



Make each planer do the work of two . . . each ounce of high speed steel, the work of ten

● To double your output on planers use ARMSTRONG Gang Planer Tools that reduce surfacing time from 50 to 75%. To make your high speed steel go farther, use ARMSTRONG TOOL HOLDERS that "Save: All Forging, 70% Grinding and **90% High Speed Steel.**" (Tests carried out covering some of the largest plants have proven that the saving in high speed steel is even in excess of "90%").

There are ARMSTRONG TOOL HOLDERS for every operation on lathes, planers, slotters and shapers, and for many operations on turret lathes and screw machines. Each is a permanent multi-purpose tool that does the work of a complete set of forged tools. Each is a stronger, more efficient tool than can be forged and will stand up to the highest speeds and heaviest feeds. Each makes an ounce of high speed steel go as far as 10 ounces will go in a forged tool.

Use ARMSTRONG TOOL HOLDERS wherever possible. On all types of work, the heaviest as well as the lightest, they save man-hours, increase machine tool output and cut high speed steel requirements to a tenth.

ARMSTRONG BROS. TOOL CO.

"The Tool Holder People"

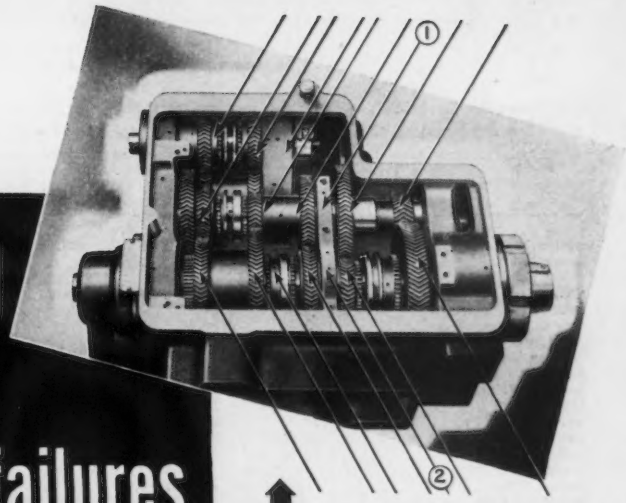
2½ to 4 in.	39	22½
4½ to 6 in.	37½	21

On butt weld and lap weld steel pipe jobbers are granted a discount of 5%. On less-than-carload shipments prices are determined by adding 25 and 30% and the carload freight rate to the base card.

F.o.b. Gary prices are two points lower discount or $4 a ton higher than Pittsburgh or Lorain on lap weld and one point lower discount, or $2 a ton higher on all butt weld.



Headstock of Sidney Lathe. Numerals 1 and 2 point to center bearings; other arrows indicate 14 Ampco bushings in the gears.

Guarded against costly failures

. . . with bushings and center bearings of wear-resisting Ampco Metal . . .

When you buy machine tools or other heavy equipment, it pays to look for parts of Ampco—the metal that stands up and gives several times the life of ordinary bronzes. Used by over 90 leading machine tool manufacturers.

Ampco is not an ordinary alloy, but a special metal produced by an engineering and research staff of metallurgical specialists under strict laboratory control, and applied with the cooperation of the national organization of Ampco Field Engineers. The range of Ampco grades provides unusual combinations of physical properties to resist wear, corrosion, shock, etc.

Send for bulletins which will aid you as a buyer and user of machinery — or let us help you specifically with your design problems. Write today.

Design for wear resistance —at lower cost with welded overlays of

AMPCO-TRODE

For bearing surfaces and other points subject to constant wear, corrosion, or other severe conditions, it is often unnecessary to provide a solid piece of wear-resisting metal. Ampco-Trode coated welding rod is widely used to overlay such surfaces with a deposit of Ampco Metal which gives the same result at a fraction of the cost. Any grade of Ampco can be welded to practically any other metal. 5 grades to meet your special requirements.

Write for bulletins.

For replacements

When you experience the failure of bronze parts—perhaps installed years before Ampco became widely known — replace them with Ampco. Ask nearest Ampco Field Engineer for suggested procedure and Ampco Metal stock list to meet the specific needs of your Maintenance Department.

Ampco Metallurgical Specialties

Ampco Metal (a special alloy of the aluminum bronze class) . . . Ampcoloy (general industrial bronzes) . . . Special Custom Copper-base Alloys.

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable.

(2) Price shown is for low-phosphorous iron; high-phosphorous sells for $28.50 at the furnace.

(3) Eastern Gas & Fuel Associates, Boston, is permitted to sell pig iron produced by its selling company. Effective Feb. 1, 1944, Mystic Iron will be sold without the above OPA price relief grant of $2 per ton.

(4) E. & G. Brooke Co. permitted to charge $1.00 per ton extra.

(5) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 per cent to 2.25 per cent); phosphorous differentials, a reduction of 38c. per ton for phosphorous content of 0.70 per cent and over; manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. For ton lots f.o.b. shipping point, in cents per lb.

Copper, electrolytic, 150 and 200 mesh	21⅛ to 23⅛c.
Copper, reduced, 150 and 200 mesh	20½ to 25½c.
Iron, commercial, 100 and 200 mesh, 96 + % Fe	13½ to 15c.
Iron, crushed, 200 mesh and finer, 90 + % Fe	4c.
Iron, hydrogen reduced, 300 mesh and finer, 98½ + % Fe	63c.
Iron, electrolytic, unannealed, coarser than 300 mesh, 99 + % Fe	30 to 33c.
Iron, electrolytic, annealed minus 100 mesh, 99 + % Fe	42c.
Iron, carbonyl, 300 mesh and finer, 98-99.8 + % Fe	90c.
Aluminum, 100 and 200 mesh	*23 to 27c.
Antimony, 100 mesh	20.6c.
Cadmium, 100 mesh	$1
Chromium, 150 mesh	$1.03
Lead, 100, 200 & 300 mesh, 11½ to 12½c.	
Manganese, 150 mesh	51c.
Nickel, 150 mesh	51½c.
Solder powder, 100 mesh, 8½c. plus metal	
Tin, 100 mesh	58¾c.
Tungsten metal powder, 98%-99%, any quantity, per lb.	$2.60
Molybdenum powder, 99%, in 200-lb. kegs, f.o.b. York, Pa., per lb.	$2.60
Under 100 lb.	$3.00

*Freight allowed east of Mississippi.

BOILER TUBES

Seamless Steel and Lap Weld Commercial Boiler Tubes and Locomotive Tubes, Minimum Wall. Net base prices per 100 ft. f.o.b. Pittsburgh, in carload lots.

	Seamless Cold Drawn	Seamless Hot Rolled	Lap Weld Hot Rolled
2 in. o.d. 13 B.W.G.	15.03	13.04	12.33
2½ in. o.d. 12 B.W.G.	20.21	17.54	16.58
3 in. o.d. 12 B.W.G.	22.48	19.50	18.35
3½ in. o.d. 11 B.W.G.	28.37	24.62	23.15
4 in. o.d. 10 B.W.G.	35.20	30.54	28.66

(Extras for less carload quantities)

40,000 lb. or ft., and over	Base
30,000 lb. or ft. to 39,999 lb. or ft.	5%
20,000 lb. or ft. to 29,999 lb. or ft.	10%
10,000 lb. or ft. to 19,999 lb. or ft.	20%
5,000 lb. or ft. to 9,999 lb. or ft.	30%
2,000 lb. or ft. to 4,999 lb. or ft.	45%
Under 2,000 lb. or ft.	65%

PRICES

BOLTS, NUTS, RIVETS, SET SCREWS

Bolts and Nuts
(F.o.b. Pittsburgh, Cleveland, Birmingham or Chicago)

Machine and Carriage Bolts:

	Per Cent Off List
½ in. & smaller x 6 in. & shorter	65½
9/16 & ⅝ in. x 6 in. & shorter	63½
¾ to 1 in. x 6 in. & shorter	61
1⅛ in. and larger, all length	59
All diameters over 6 in. long	59
Lag, all sizes	62
Plow bolts	65

Nuts, Cold Punched or Hot Pressed:
(Hexagon or Square)

½ in. and smaller	62
9/16 to 1 in. inclusive	59
1⅛ to 1½ in. inclusive	57
1⅝ in. and larger	56

On above bolts and nuts, excepting plow bolts, additional allowance of 10 per cent for full container quantities. There is an additional 5 per cent allowance for carload shipments.

Semi-Fin. Hexagon Nuts	U.S.S.	S.A.E.
7/16 in. and smaller	..	64
½ in. and smaller	62	..
½ in. through 1 in.	..	60
9/16 to 1 in.	59	..
1⅛ in. through 1½ in.	57	58
1⅝ in. and larger	56	..

In full container lots, 10 per cent additional discount.

Stove Bolts

Packages, nuts loose	71 and 10
In packages, with nuts attached	71
In bulk	80

On stove bolts freight allowed up to 65c. per 100 lb. based on Cleveland, Chicago, New York on lots of 200 lb. or over.

Large Rivets *(½ in. and larger)*

	Base per 100 lb.
F.o.b. Pittsburgh, Cleveland, Chicago, Birmingham	$3.75

Small Rivets *(7/16 in. and smaller)*

	Per Cent Off List
F.o.b. Pittsburgh, Cleveland, Chicago, Birmingham	65 and 5

Cap and Set Screws

	Per Cent Off List
Upset full fin. hexagon head cap screws, coarse or fine thread, up to and incl. 1 in. x 6 in.	64
Upset set screws, cup and oval points	71
Milled studs	46
Flat head cap screws, listed sizes	36
Fillister head cap, listed sizes	51

Freight allowed up to 65c. per 100 lb. based on Cleveland, Chicago or New York on lots of 200 lb. or over.

RAILS, TRACK SUPPLIES
(F.o.b. Mill)

Standard rails, heavier than 60 lb., No. 1 O.H., gross ton	$40.00
Angles bars, 100 lb.	2.70
California Ports	$3.15

(F.o.b. Basing Points)	*Per Gross Ton*
Light rails (from billets)	$40.00
Light rails (from rail steel)	39.00

	Base per Lb.
Cut spikes	3.00c.
Screw spikes	5.15c.
Tie plates, steel	2.15c.
Tie plates, Pacific Coast	2.30c.
Track bolts	4.75c.
Track bolts, heat treated, to railroads	5.00c.
Track bolts, jobbers discount	63-5

Basing points, light rails, Pittsburgh, Chicago, Birmingham: spikes and tie plates—Pittsburgh, Chicago, Portsmouth, Ohio, Weirton, W. Va., St. Louis, Kansas City, Minnequa, Colo., Birmingham and Pacific Coast ports; tie plates alone—Steelton, Pa., Buffalo. Spikes alone—Youngstown, Lebanon, Pa., Richmond, Oregon and Washington ports, add 25c.

ROOFING TERNE PLATE
(F.o.b. Pittsburgh, 112 Sheets)

	20x14 in.	20x28 in.
8-lb. coating I.C.	$6.00	$12.00
15-lb. coating I.C.	7.00	14.00
20-lb. coating I.C.	7.50	15.00

How Amsco Met Requirements for Easy Machining Non-Magnetic Alloy Parts.....

Non-magnetic parts having high tensile strength were required for special tractors. Amsco received an inquiry for a quantity of steering lever sets, with austenitic manganese steel specified; but the large amount of machining required ruled this metal out as the extreme toughness which gives it its durability also makes manganese steel difficult to machine with tools.

Amsco Alloy F-8N, a variation of the well known 18-8 grade of chromium-nickel alloy, having a magnetic permeability of approximately 1.003, was found satisfactory for these parts.

Small areas on each casting were to be flame-hardened (on the original cast steel specification). As it is not practicable to harden this particular grade of Amsco Alloy, a special hard-surfacing welding rod was developed by Amsco for the job. The castings were then coated on the required areas with this rod, before finish grinding.

Pictures R-891, 892 and 893 are reproductions of radiographs showing progressive stages in chill and heading practice to prevent shrinkage in the lever castings. The problem in producing these castings was the necessity of exceptional soundness. The shrinkage voids shown in R-891 and 892 were finally obviated (as seen in R-893) by various expedients that concentrated the shrinkage areas in a position where a feeder head could supply the necessary metal.

Inquiries regarding unusual requirements are always welcome at Amsco.

PRICES

Ferromanganese

78-82% manganese, maximum contract base price per gross ton, lump size, f.o.b. car at Baltimore, Philadelphia, New York, Birmingham, Rockdale, Rockwood, Tenn.

Carload lots (bulk)	$135.00
Ton lots (packed)	141.00
Less ton lots (packed)	148.50

Premium, $1.70 for each 1% above 82% Mn: penalty, $1.70 for each 1% below 78%.

Electrolytic Manganese

99.9% manganese, maximum base contract price per lb. of metal, bulk, f.o.b. shipping point, with freight allowed to destination. Size 1" x D.

	Eastern Zone	Central Zone	Western Zone
Carload lots	37.60c.	37.85c.	38.15c.
l.c.l. lots	39.60c.	38.60c.	40.65c.

Spiegeleisen

Maximum base contract prices, per gross ton, lump, f.o.b. Palmerton, Pa.

	16-19% Mn 1% max. Si	19-21% Mn 1% max. Si	26-28% Mn 1% max. Si
Carloads	$35.00	$36.00	$49.50
Less ton*	47.50	48.50	62.00

Electric Ferrosilicon

OPA maximum base price cents per lb. contained Si, lump size in carlots, f.o.b. shipping point with freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
50% silicon	6.65c.	7.10c.	7.25c.
75% silicon	8.05c.	8.20c.	8.75c.

Spot sales 45c. per lb. higher or 50% Si; 30c. for 75% Si. For extras and premiums see MPR 405.

Silvery Iron

(Per Gross Ton, base 6.00 to 6.50 Si)

F.o.b. Jackson, Ohio	$29.50*
Buffalo	30.75*

For each additional 0.50% silicon add $1 a ton. For each 0.50% manganese over 1% add 50c. a ton. Add $1 a ton for 0.75% phosphorous or over.

*Official OPA price established June 24, 1941.

Bessemer Ferrosilicon

Prices are $1 a ton above silvery iron quotations of comparable analysis.

Silicon Metal

OPA maximum base price per lb. of contained Si, lump size, f.o.b. shipping point with freight allowed to destination, for l.c.l. above 2000 lb., packed.

	Eastern Zone	Central Zone	Western Zone
96% Si, 2% Fe	13.10c.	13.55c.	16.50c.
97% Si, 1% Fe	13.45c.	13.90c.	16.80c.

Ferrosilicon Briquets

OPA maximum base price per lb. of briquet, bulk, f.o.b. shipping point with freight allowed to destination. Approximately 40% silicon.

	Eastern Zone	Central Zone	Western Zone
Car lots	3.35c.	3.50c.	3.65c.

Spot prices ¼c. higher per lb. of briquet. For premiums and extras see MPR 405.

Silicomanganese

(Per gross ton, delivered, carloads, bulk)

3.00 carbon	$120.00*
2.50 carbon	125.00*
2.00 carbon	130.00*
1.00 carbon	140.00*
Briquets, contract, basis carlots, bulk freight allowed, per lb.	5.80c.†
Packed	6.05c.†
Less ton lots	6.55c.†

*Spot prices are $5 per ton higher.
†Spot prices ¼c. higher.

Ferrochrome

(65-72% Cr, 2% max. Si)

OPA maximum base contract prices per lb. of contained Cr, lump size in carlots, f.o.b. shipping point, freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
0.03% carbon	25.00c.	25.40c.	26.00c.
0.06% carbon	23.00c.	23.40c.	24.00c.
0.10% carbon	22.50c.	22.90c.	23.50c.
1.00% carbon	20.50c.	20.90c.	21.50c.
2.00% carbon	19.50c.	19.90c.	20.50c.

Spot prices are ¼c. higher per lb. contained Cr. For extras and premiums see MPR 407.

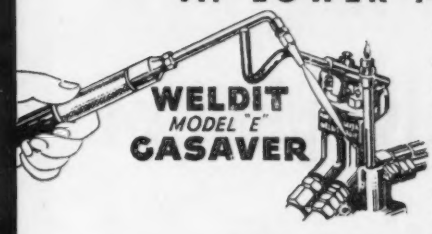
PRICES

Other Ferroalloys

Ferrotungsten, Standard grade, lump or ¼X down, packed, f.o.b. producer's plant at Niagara Falls, New York, Washington, Pa., York, Pa., per lb. contained tungsten. 10,000 lb. or more	$1.90
Ferrovanadium, 30-35%, contract basis, f.o.b. producer's plant, usual freight allowances, any quantity, per lb. contained vanadium.	
Open Hearth	$2.70
Crucible	$2.80
Primos	$2.90
Cobalt, 97% min., keg packed, contract basis, f.o.b. producer's plant, usual freight allowances, per lb. of cobalt metal	$1.50
Vanadium pentoxide, 88%-92% V_2O_5 technical grade, contract basis, any quantity, per lb. contained V_2O_5	$1.10
Ferroborom, contract basis, 17.50% borom minimum, f.o.b. Niagara Falls, carlots, per lb. alloy	$1.20
Ton lots	$1.25
Silcaz No. 3, contract basis, f.o.b. Niagara Falls, all quantities, per lb. of alloy	23c.
Silvaz No. 3, contract basis, f.o.b. Niagara Falls, all quantities, per lb. of alloy	40c.
Grainal, f.o.b. Bridgeville, Pa., freight allowed 100 lb. and over, maximum based on rate to St. Louis, per lb.	45c.
Bortam, f.o.b. Niagara Falls	
Ton lots, per lb.	45c.
Less ton lots, per lb.	50c.
Borosil, 3% to 4% boron, 40 to 45% silicon, f.o.b. Philo, Ohio, per lb. contained boron	$6.25
Ferrocolumbium, 50% to 60%, f.o.b. Niagara Falls, ton lots, per lb. contained columbium	$2.25
Less ton lots	$2.30
Ferrotitanium, 40%-45%, f.o.b. Niagara Falls, N. Y., ton lots, per lb. contained titanium	$1.23
Less ton lots	$1.25
Ferrotitanium, 20%-25%, 0.10 C max., ton lots, per lb. contained titanium	$1.35
Less ton lots	$1.40
High-carbon ferrotitanium, 15%-20%, 6%-8% carbon, contract basis, f.o.b. Niagara Falls, N. Y., freight allowed East of Mississippi River, North of Baltimore and St. Louis, per gross ton	$142.50
3%-5% carbon	$157.50
Ferrophosphorus, 18% electric or blast furnace, f.o.b. Anniston, Ala., carlots, with $3 unitage freight equaled with Rockdale, Tenn., per gross ton	$58.50
Ferrophosphorus, electrolytic 23-26%, carlots, f.o.b. Monsanto (Siglo), Tenn., $3 unitage freight equalized with Nashville, per gross ton	$75.00
Ferromolybdenum, 55-75 per cent, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum	95c.
Calcium molybdate, 40%-45%, contract basis, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum	80c.
Molybdenum oxide briquettes, 48%-52% Mo, f.o.b. Langeloth, Pa., per lb. contained Mo	80c.
Molybdenum oxide, in cans, f.o.b. Langeloth and Washington, Pa., per lb. contained Mo	80c.
Zirconium, 35-40%, contract basis, carloads in bulk or package, per lb. of alloy	15c.
Less ton lots	16c.
Zirconium, 12-15%, contract basis, carlots, bulk, per gross ton	$102.50
Packed	$107.50
Less ton lots	$112.50
Alsifer (approx. 20% Al, 40% Si and 40% Fe), contract basis, f.o.b. Niagara Falls, per lb.	7.50c.
Ton lots	8c.
Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.	
Car lots	8.75c.
Ton lots	9.25c.
Less ton lots	9.75c.

Safe Welding

AT LOWER PRODUCTION COSTS



The Weldit Gasaver shuts off the welding flame when not in use. . . . Conserves essential materials by cutting oxygen and acetylene consumption as much as *fifty* per cent. Prevents injury to workmen—or sudden fires—from dangerous idle torch flames. . . . Adjustment remains unaltered between welds.

When the Weldit Gasaver has been installed, you simply hang idle torch on the handy lever rod. Weight of torch pulls rod down, thus automatically shutting off supply lines. Relight instantly by passing torch over Gasaver pilot light. No bother. . . . No time lost. . . . *No readjusting required.* . . . Price $10.00 at Detroit. Order today.

Better Soldering, Annealing and Heating Jobs

The Weldit Model CW Blowpipe is in daily use by many foremost industrial plants. . . . Built in accordance with the recommendations of leading fabricators of sheet metal products. . . . Operates on either natural gas, manufactured gas, or other low temperature fuel gas and compressed air. Stands up under rough shop use. . . . Send for literature.

WELDIT ACETYLENE CO.
641 BAGLEY AVENUE • DETROIT 26, MICH.

How many WORDS in a speech?

Usually too many, we think. We're not very long on words here at Dunbar's. Springmaking is our business and we prefer to stick to it. We'd rather show you how your spring may be improved, perhaps at lower cost—or possibly at savings in assembly time. We like to work on new spring developments, too. It's sort of a hobby with us.

Good spring action speaks louder than words!

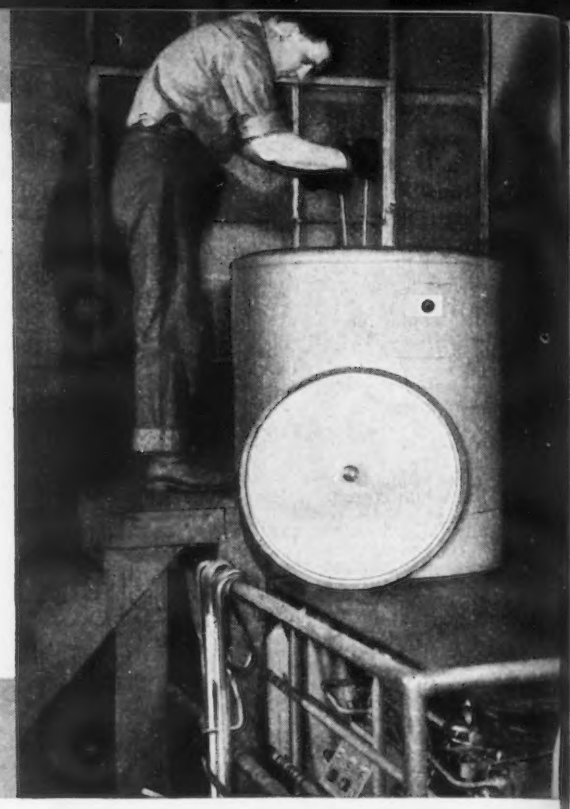
COLD TREATING now permits salvaging of broken cutting tools!



Chilling in Deepfreeze at -120° F., After Brazing Operation, Restores Original Hardness to H.S.S. Formed Cutter...

The 8¾" x 1¼" special formed milling cutter shown above was broken in two in a prominent machine tool manufacturer's plant.* Ordinarily this expensive tool would have been scrapped because welding or brazing would soften the cutting edge. However, this company had previously hardened tool steels by chilling in a Deepfreeze, and thought it possible to restore hardness to the cutting edges of the brazed tool. After a brazing operation and sharpening to its original form, the cutter was chilled at −120° F. for two hours in a Deepfreeze Cascade −120° F. Industrial Chilling Machine. The result was that the original hardness of the teeth at the point of the weld was restored.

Now with this new method of treating welded and brazed cutting tools it is no longer necessary to scrap all broken tools. If it is possible to restore a broken tool to working condition by welding or brazing, cold treating will return the cutting teeth at the point of weld to their original hardness. Thus it is often possible to salvage expensive tools that otherwise would be scrapped. In addition, production delays and costly machine downtime are eliminated.

*Manufacturer's name upon request.

FIND OUT HOW YOU CAN USE A DEEPFREEZE IN YOUR PLANT...

For the complete and latest data on the use of Cold Treatment for metals in industry today, get the new Deepfreeze Metal Chilling Data Book. In this handy working guide on the use of industry's newest production tool you can learn how to use sub-zero temperatures for the shrinking, testing, hardening and stabilization of metals in your plant. A free copy can be obtained by writing Deepfreeze, North Chicago, Illinois. Write today for as many copies as you need.

REMOVES 1000 BTU's PER HOUR AT −120° F. WHEN WORK IS IMMERSED IN CONVECTION LIQUID...

In addition to the application described above, Deepfreeze Industrial Chilling Machines are finding unlimited use in a wide variety of industrial fields. The Deepfreeze Cascade −120° F. Industrial Chilling Machine has a chilling capacity for high production metal chilling of many parts where large quantities of heat must be removed fast.

Let Deepfreeze engineers assist you in obtaining the advantages of cold treating. Send an outline of your problem together with parts or prints for a preliminary analysis or test. There is no obligation.

Jobs for Disabled Soldiers

THE job that industry has done to support and to forward the war effort is one that can well be a matter of pride to all of those engaged in it. With negligible exceptions which have been over-emphasized, both management and labor have lived up to their duties and obligations as true Americans.

But it is not yet "over over there" and it will not be over over here until those whom circumstance has selected to bear the brunt of protecting our way of life have come back home and have found a welcome on the door mat.

A bonus of $300 per, or whatever may be offered by our government in return for the willingness to risk life and limb surely is not an adequate measure of our conception of what we owe the defenders of American liberty. If it were, then liberty would not be worth buying at that price.

America will owe these boys more than that. It will owe them an opportunity to make a living. They will expect that and rightly so.

We in this country have eaten well, have slept well, have been kept immune from alarms and dangers primarily because under our democratic system we have been able to send millions of boys and young men abroad to keep us that way. Our way of life has not been particularly disturbed; theirs has been disrupted and disturbed beyond our conception.

To those who come back totally disabled, this country will owe a living. To those who come back partially disabled it will owe the opportunity to make a living, plus all of the aid we can give them to make this possible.

Right now is none too soon to begin thinking about that. For casualties are beginning to make their appearance and some of them have been none too well treated.

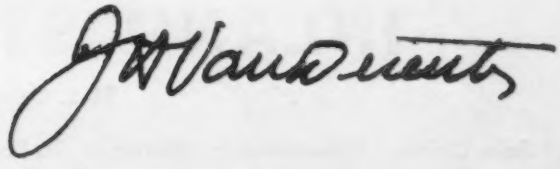
The question arises as to whether government or private industry should take these boys in hand and try to fit them for doing useful work. I personally think that this is a job and a responsibility for private enterprise. It knows more about the work that it needs to have done than does government and is better fitted to train these boys for that work.

Due to the great advances in industrial mechanization, the opportunities for fitting partially handicapped people into industry are now almost unlimited. Brain today is a much greater industrial employment asset than is brawn.

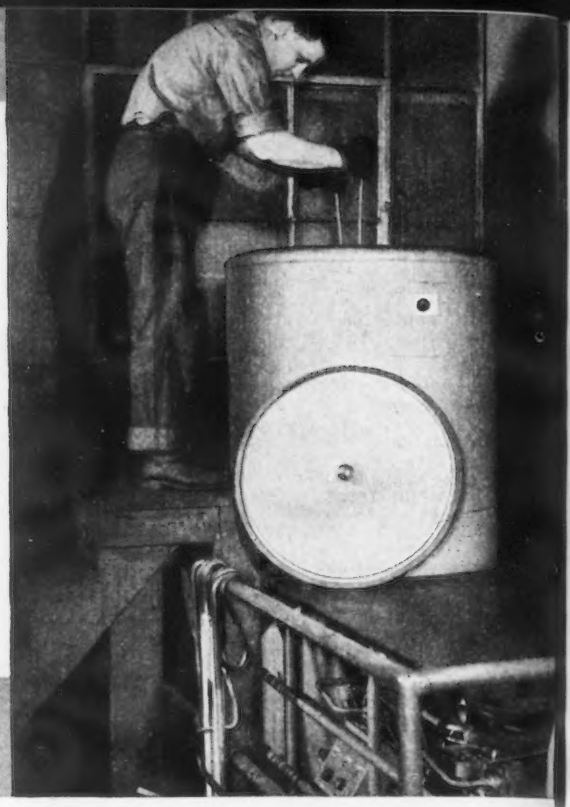
One of the psychological hurdles in this is the attitude of the crippled soldier to himself. If he is led to believe that nobody wants him it is just too bad. If, on the other hand, he is led to believe that the loss of an arm or leg entitles him to a sinecure job for life, that is too bad also. Somewhere in between is the answer.

The big thing is to make him realize that he can be just as useful a member of society as are those of his brethren who have stayed at home unscathed by war. As useful and as welcome.

That is a job for every American employer to undertake right now. You are proud of having turned out material with which to win the war. Be ready to be even prouder of having arranged to take into your factories and offices those who have really sacrificed to win the war.



COLD TREATING now permits salvaging of broken cutting tools!



Chilling in Deepfreeze at -120° F., After Brazing Operation, Restores Original Hardness to H.S.S. Formed Cutter...

Jobs for Disabled Soldiers

THE job that industry has done to support and to forward the war effort is one that can well be a matter of pride to all of those engaged in it. With negligible exceptions which have been over-emphasized, both management and labor have lived up to their duties and obligations as true Americans.

But it is not yet "over over there" and it will not be over over here until those whom circumstance has selected to bear the brunt of protecting our way of life have come back home and have found a welcome on the door mat.

A bonus of $300 per, or whatever may be offered by our government in return for the willingness to risk life and limb surely is not an adequate measure of our conception of what we owe the defenders of American liberty. If it were, then liberty would not be worth buying at that price.

America will owe these boys more than that. It will owe them an opportunity to make a living. They will expect that and rightly so.

We in this country have eaten well, have slept well, have been kept immune from alarms and dangers primarily because under our democratic system we have been able to send millions of boys and young men abroad to keep us that way. Our way of life has not been particularly disturbed; theirs has been disrupted and disturbed beyond our conception.

To those who come back totally disabled, this country will owe a living. To those who come back partially disabled it will owe the opportunity to make a living, plus all of the aid we can give them to make this possible.

Right now is none too soon to begin thinking about that. For casualties are beginning to make their appearance and some of them have been none too well treated.

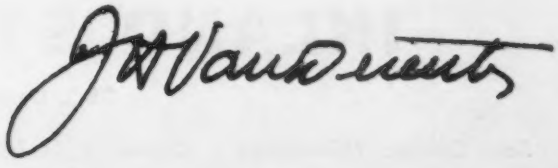
The question arises as to whether government or private industry should take these boys in hand and try to fit them for doing useful work. I personally think that this is a job and a responsibility for private enterprise. It knows more about the work that it needs to have done than does government and is better fitted to train these boys for that work.

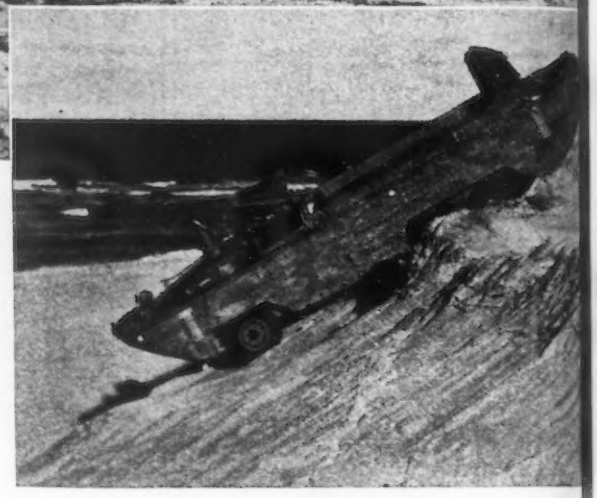
Due to the great advances in industrial mechanization, the opportunities for fitting partially handicapped people into industry are now almost unlimited. Brain today is a much greater industrial employment asset than is brawn.

One of the psychological hurdles in this is the attitude of the crippled soldier to himself. If he is led to believe that nobody wants him it is just too bad. If, on the other hand, he is led to believe that the loss of an arm or leg entitles him to a sinecure job for life, that is too bad also. Somewhere in between is the answer.

The big thing is to make him realize that he can be just as useful a member of society as are those of his brethren who have stayed at home unscathed by war. As useful and as welcome.

That is a job for every American employer to undertake right now. You are proud of having turned out material with which to win the war. Be ready to be even prouder of having arranged to take into your factories and offices those who have really sacrificed to win the war.





"Ducks" Made of Inland Steel

Our fighting men call this 2½-ton amphibian truck the "duck", because it travels equally well either on land or in the water. Its water-tight steel hull encases the frame assembly below which are mounted the springs, brackets, and wheels—it is a motorized boat on wheels. In the water the "duck" is driven by a rear mounted propellor.

At battle fronts these seagoing trucks serve our fighters by establishing beach heads and bridge heads, by carrying men and supplies from ocean freighters—across beaches, lakes and rivers to inland depots. They are used in reconnaissance work in coastal waters, and over land where roads and bridges do not exist. They can often be seen pulling artillery into position.

Inland Steel Co. supplies thousands of tons of plates and sheets used in the construction of these unique amphibian trucks—or "ducks." Other large tonnages of flat rolled products move daily from the Inland mills to builders of many types of transport, such as ships, trucks, barges, etc.

When the war is won steel from Inland will again be used to fill the peacetime transportation needs of the country.

The IRON AGE
FEB. 10, 1944

NEWS FRONT

► This year's quota for Lake Superior ores has been set at 90 million gross tons by WPB's Iron and Steel Advisory Committee.

► Attacking the WLB because it considers each labor problem individually rather than a segment of the broad labor panorama, UAW has promulgated a counter-plan of equal pay for equal work. Brought out at General Motors negotiations, the union has divided skills into six general classifications with equal compensation in the various plants.

► Aircraft electrical systems have undergone continuous evolution. Early planes used a 6-volt d.c. system, patterned after the automobile. Larger and larger planes led to the adoption of 12-volt systems and later to 27-volt d.c. now in wide use. Very large bombers now in production have such large power requirements that a 400-cycle, 120-208 volt a.c. system has been adopted.

► Recent German hit-and-run raids against English coastal towns were over so fast that 6 sec. was the average time for a Bofors engagement.

At first gunners were shaken by this new technique, but batteries were changed round and crews given physical training to fit them for split-second reactions. Now the gunners are again bringing anti-aircraft scores up to previous levels.

Another outstanding feat of British A.A. gunnery was the destruction of a Me 109G photographic reconnaissance machine flying at an altitude of seven miles over Portsmouth. Mixed batteries of 3.7 and 4.5 guns brought this plane down.

► An electrically-induced protective coating for magnesium alloys, said to make these alloys as non-corrosive and abrasion resistant as aluminum alloys, has been announced by Consolidated Vultee Aircraft Corp. The finish is very smooth, and there is a possibility that dyes can be introduced into the solution with subsequent production of a wide variety of colors.

► On Feb. 3, the first open hearth furnace of the Geneva Steel Co. was charged. Two more of the 225-ton basic open hearths will be brought into production at weekly intervals.

Also scheduled for starting in February are 63 by-product coke ovens.

► Home-made 45-lb. rails are now being produced for Brazilian railways at the Compania Siderurgica Belgo-Mineira plant. Rails heavier than 65 lb. will be made when the new National Steel Co. of Brazil plant is completed.

► The power of rumor! A month ago the Port of New York Authority received a letter from Syracuse University asking, "if there is any truth in the published story that green coffee is being dumped in New York Harbor to such an extent that navigation is impeded."

► The German State Police recently announced they were searching for 40,000 deserters.

Award of Germany's top medal, the Ritterkreuz (the Knight's Insignia of the Iron Cross, corresponding to the Pour le Mérite of the 1914-18 war) progressively declined during 1943, particularly for the Luftwaffe. In 1940 fighter pilots got the award after 30 air victories; a year later, when the Russian invasion had started, the minimum number of "kills" was fixed at 50; while today the "kills" seem to vary between 100 and 150.

Furthermore, German papers have recently complained that too many of the awards are going to generals and staff officers, or what is called the "chairborne forces."

► Vitallium, an alloy developed in halcyon days for denture casting and orthopedic applications, is now being cast to form GE turbosupercharger buckets.

From a metal master pattern, made by conventional machining methods, a bismuth split mold is cast sufficiently oversize to allow for shrinkage. Into this mold, wax is injected. These wax patterns are then embedded in a refractory investment and later melted out, leaving a cavity into which Vitallium is poured under pressure.

By this method, castings weighing up to 1 oz. and requiring a tolerance of 0.005 to 0.010 in. are now being produced on a mass production basis. Castings as large as 5 lb. are being tried.

Applications to both old and new alloys impossible to forge or machine are foreseen for precision casting.

Precision Castings of Turbosupercharger Buckets

. . . War's demand has created a commercial application for a technique used heretofore only in the dental and surgical appliance field. Small buckets for the G.E.aircraft turbosupercharger are now being made by the million out of a non-ferrous alloy called Vitallium that is difficult to machine and forge. The author describes the history of the development of the investment casting technique for this metal and illustrates the various steps in the process of making precision castings from wax patterns, the so-called lost wax process.

o o o

By ALBERT W. MERRICK

Chief, Research Department,
Austenal Laboratories, Inc., New York

o o o

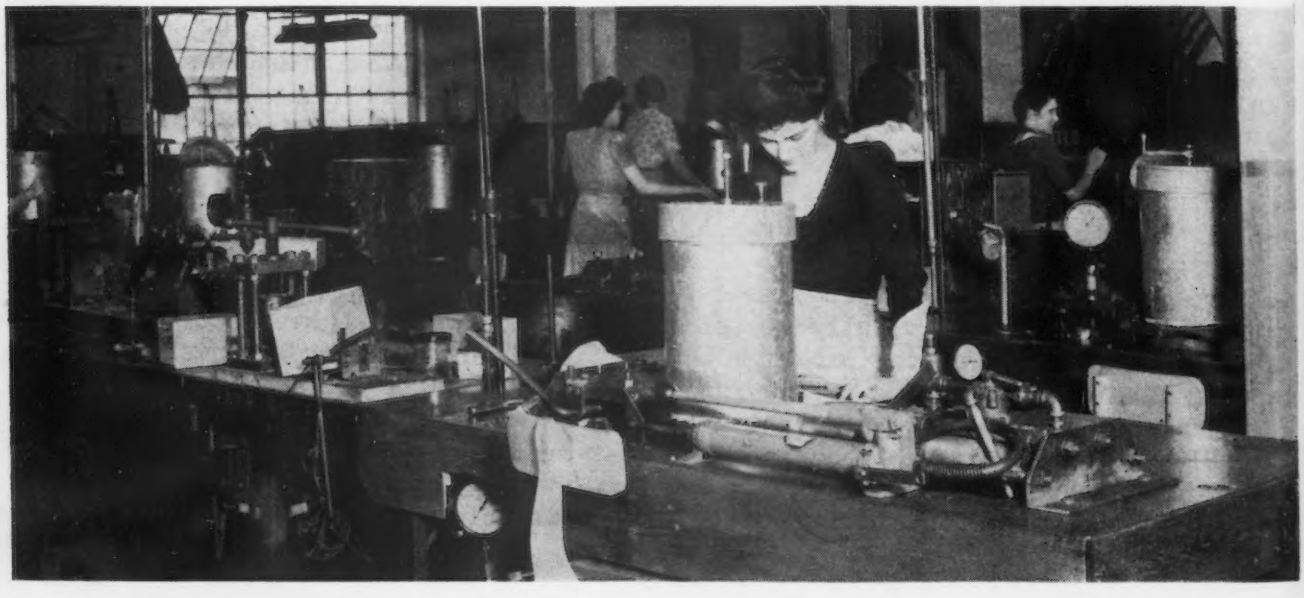
DURING wartime, many technological advances are made and the tempo of changes in techniques and methods of manufacture is greatly accelerated. Often these methods have been known and used in limited applications but not until the stress of war production are they more widely introduced and used. Such is the case of the development of precision casting, known variously as investment casting, the "lost" wax process or the dental wax process.

In the first world war, the airplane played a relatively minor part, but in the present global conflict it is playing a major role. Present conditions call for routine flight at altitudes unapproachable, even as a stunt, prior to about 1920.

The application of supercharging made flight at high altitudes possible, and the General Electric turbosupercharger has been the device most prominent in the attainment of the ever mounting ceiling altitudes. The turbosupercharger uses as a source of power the stream of incandescent exhaust gases from the engine and the turbine buckets are subjected to a combination of relatively high temperatures and stresses, vibratory and tensile, the latter due to centrifugal force.

The writer was associated with some of the metallurgical phases of the problem of alloys for certain of these applications in the late 20's. At this time, several alloys were made that had good properties at high temperatures, but were virtually un-

FIG. 1—View of the waxing department of the War Products Division of Austenal Laboratories, Inc. The girl in the foreground is forming the wax patterns for producing G. E. turbosupercharger buckets of Vitallium alloy by the investment method. The molds are made in split halves of a special alloy from a master pattern and provide for five buckets. Wax formulation and proper temperature and pressure control are essential in obtaining a precise wax pattern that will not deform during later handling.



DR. SANFORD A. MOSS, who has pioneered in the development of the turbosupercharger at General Electric Co. Precision casting of the individual buckets of the gas turbine end of the supercharger illustrated is the subject of the accompanying article.

Development of the G.E. Turbosupercharger

The father of the modern turbosupercharger, which is responsible for putting our bombers and fighters up in the stratosphere, is Dr. Sanford A. Moss of the General Electric Co. By coincidence, he began studying the basic problem of the gas turbine as a project for his doctor's thesis at Cornell University in 1903, the same year that the Wright brothers made their historic flight at Kittyhawk. Dr. Moss continued his research on the gas turbine with General Electric and also played an important part in the development of the centrifugal compressor which could be directly connected to the wheel of a turbine operating on the exhaust gases of an internal combustion engine.

The next significant step in turbosupercharger development took place in 1917 when the National Advisory Committee for Aeronautics asked General Electric to undertake the development of turbosuperchargers for lifting the "ceiling" of fighting planes, which even by that time were being operated at altitudes as high as 20,000 to 24,000 ft. The first such unit was installed on a Liberty engine in 1918 and was tried out experimentally on Pike's Peak (elev. 14,109 ft.) At that altitude a 350-hp. Liberty engine could deliver only 230 hp. With the turbosupercharger, the output was stepped up to 356 hp. That same year a plane was flown at 18,400 ft. with a turbosupercharged engine and by 1920 the ceiling had been pushed up to 38,180 ft. and a year later to 40,800 ft. General Electric's development of the turbosupercharger continued in cooperation with the Army Air Corps engineers during the 1930's and today it has become standard equipment for most of our high-altitude fighters and bombers.

When production of superchargers began to grow in 1939, a forged dovetail type of bucket was being used, made of special Cyclops alloy 17W, which was the best material for the high temperature service required that G.E. knew of at the time. Although this material at 1600 deg. F. would stand the stresses imposed at the standard rated speeds of two styles of impellers, in cooperation with the Army Air Forces every effort was made to develop bucket materials with greater strength at this elevated temperature so that superchargers could be run at a higher speed. By thus increasing the air pressure in the manifold, the planes could be operated at higher altitudes. Improved strength of bucket materials was also desired to obtain longer service life of the bucket.

The precision casting of supercharger buckets made of Vitallium alloy was worked out with Austenal Laboratories, Inc., and is described in the accompanying article. Tests have proved that superchargers with Vitallium buckets could be operated at higher speeds resulting in gains of 3000 to 5000 ft. in the altitude at which planes can be flown at full power.

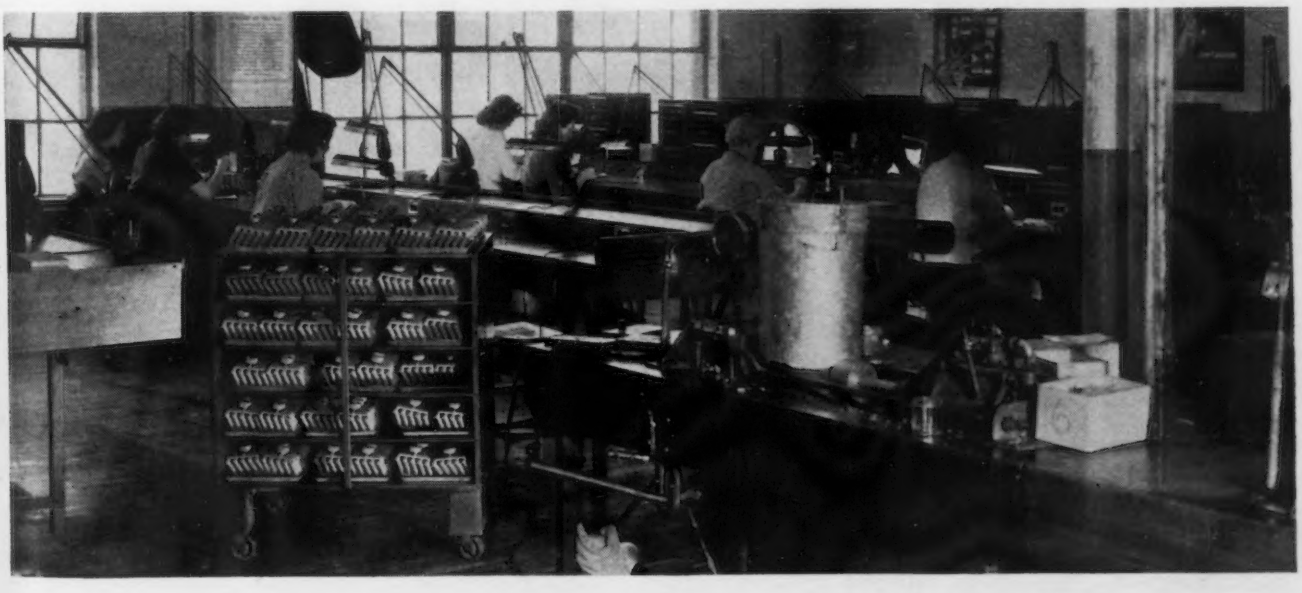
Originally the change to cast Vitallium was made using the same conventional dovetail or roll-and-neck design as employed with the forged bucket. Holding the same tolerances in the cast dovetail as for the machined bucket proved difficult and the drilling and slotting of over 100 holes was costly and consumed many manhours. The next logical development was the use of cast Vitallium buckets with the base so designed that they could be automatically welded to the rim of the wheel. (Fig. 10.) This technique has progressed to the point where today the majority of turbine wheels made have welded cast Vitallium buckets which not only provide for improved performance at high altitudes but also greatly reduce the number of manhours required to manufacture a wheel.

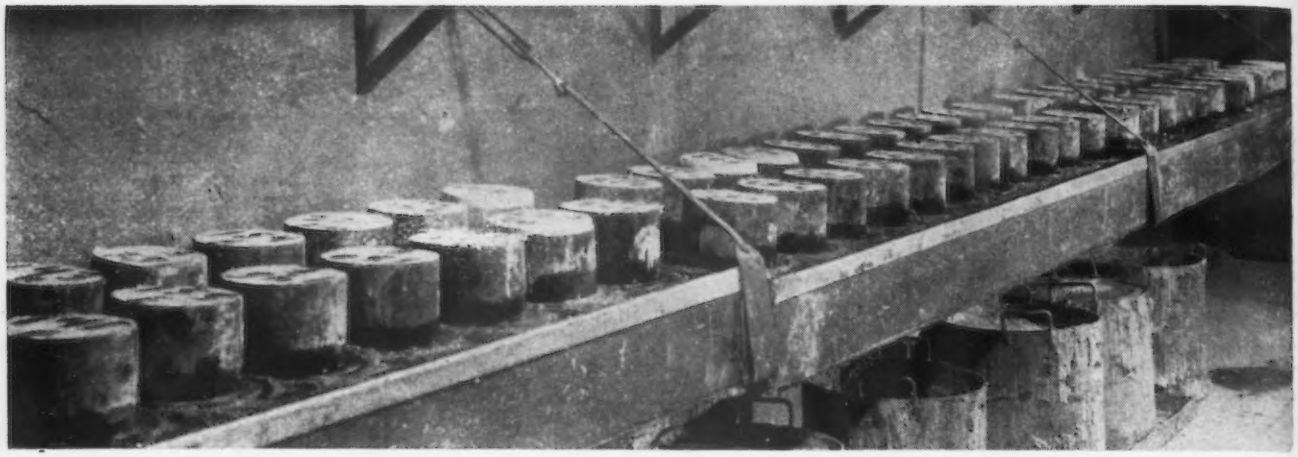
forgable and machined with great difficulty. Casting was considered, but small parts of special alloys, weighing less than 1 oz. in weight, just did not fit into the techniques and equipment of the existing state of the casting art at that time.

In 1933 the writer joined the organization of Austenal Laboratories, Inc. This corporation grew out of an older company, Erdle & Prange, founded by Reiner W. Erdle and Charles H. Prange, who are now president and vice-president respectively of Austenal Laboratories, Inc. This firm was engaged primarily in the dental field at this time and had developed alloys in conjunction with Haynes Stellite Co. Austenal further developed and patented an alloy for denture work, called Vitallium,* that was meeting with unprecedented success in the form of small castings for the construction of full and partial dentures. Vitallium is a cobalt-chromium-molybdenum (or tungsten) alloy, with a melting point of approximately 2500 deg. F., which is 750 to 1000 deg. F. above that of the customary gold alloys used for similar dental applications.

*Registered trade mark of Austenal Laboratories, Inc.

FIG. 2—Another view of the Austenal waxing department. Girls at the benches are connecting with runners four sections of wax patterns and are attaching the riser, which is formed separately from the bucket pattern sections. All that is needed for wax pattern assembly is an electric iron.





ABOVE

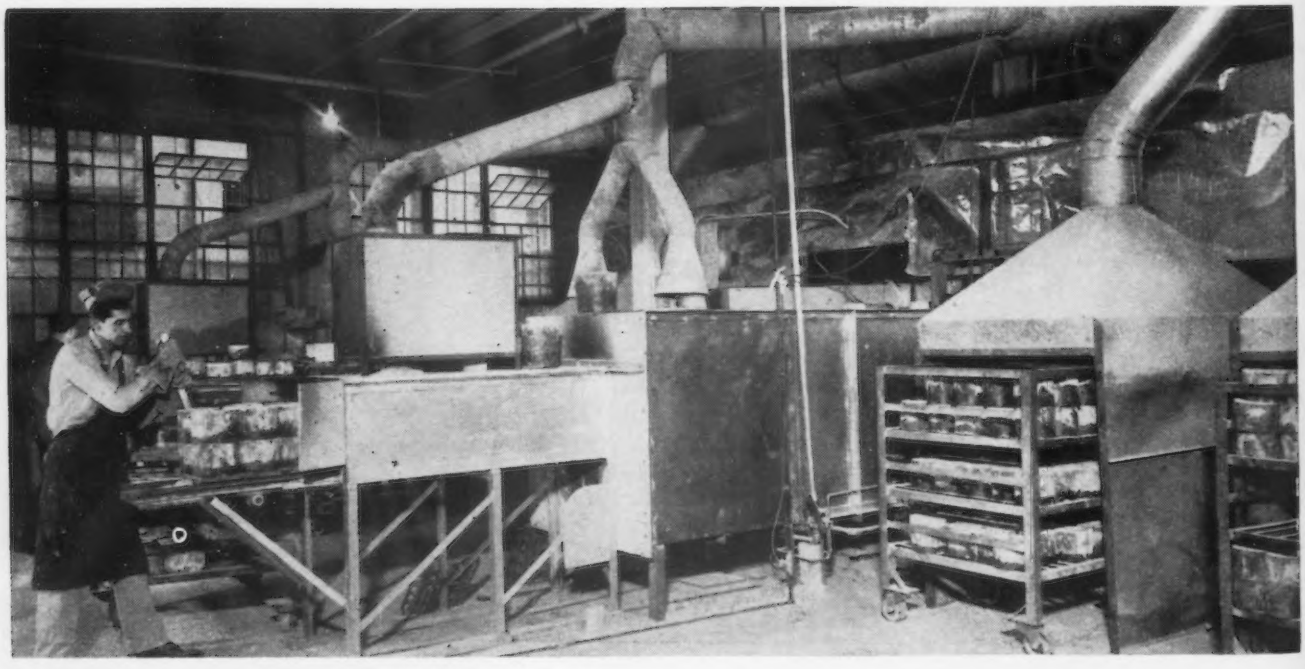
FIG. 4—Over these steam tables the flasks or cases are inverted, allowing the wax patterns to melt and run out, to be collected in the large buckets below. The wax can be reclaimed and used over many times.

LEFT

FIG. 3—Here the investment material, which contains a highly refractory sand, is poured around the wax molds in elliptically shaped flasks or cases made of a high nickel-chrome alloy. Facing material is first applied on the wax patterns and allowed to dry, depositing refractory material in fine crystalline form (see racks at rear). The investment sand is being mixed at the right in buckets or troughs. After the flasks are filled with what appears to be a wet cement, they are vibrated mechanically on the tables shown in the foreground.

BELOW

FIG. 5—In this battery of gas-fired furnaces, the flasks are baked at temperatures rising above 1800 deg. F. at the discharge end. Here a worker is shown racking a tray load of flasks into the charging end of the furnace. This action pushes the whole line of trays forward. Cases are upside down to keep dust out of molds. At the right is an exhausted booth for drawing heat off poured molds.



In order to produce sound, smooth castings from such an alloy, a totally new technique was devised, employing highly refractory mold materials, called "investments" in the dental field, that were suitable for the alloy.

Denture Casting Technique

In the making of a denture casting, a model is first formed by pouring the investment into an impression. This is removed when the "set" has taken place and on this model, a wax pattern for the casting is executed by hand, by a highly skilled technician. Sprues are attached and the model placed in a flask (metal ring) and more of the investment poured over it. After this has set, the mold is dried, placed in a furnace and gradually heated to some temperature above the red range, often as high as 2200 deg. F. The wax melts out in the early stages and the heated mold is taken out and cast by one of several methods, usually centrifugally or by air pressure.

The possibilities of this process for other forms of castings naturally appealed to one whose prior experience had been entirely in the industrial field. The problem of turbine buckets from refractory alloys for superchargers suggested itself but there was little development work of this kind going on at this time.

Austenal, however, had certain applications of its own, for which special techniques and equipment were developed, and various types of castings, other than dental, were made from time to time. Using these techniques, for example, dies were cast for use in molding ceramic parts and also dies for use in molding plastics by compression. Some castings made were as large as a die for a one piece molding of a small table model radio cabinet, others were only a fraction of an ounce in weight.

By 1934 a complete technique for the casting of Vitallium finger rings was developed and for some years these were made on a small scale as novelties. These had such an appeal on account of their clean-cut detail and finish that a regular business developed in rings which hit its seasonal peak for the Christmas trade each year. This department flourished until the demand for strategic metals during the war cut it off.

Concurrently with these developments was another that from small beginnings was destined to occupy an important place in Austenal's prewar business activities.

A Texas dentist, Dr. Taylor Wheat, who was an enthusiastic user of Vitallium alloy in partial denture practice, had an orthopedic surgeon friend, Dr. Charles S. Venable, who was interested in research on the effects of metals on bone. Plates and screws of most metals are very irritating to bone and tissue and for this reason were never widely employed in the fixation of fractures. When used for fixation of a long bone in the limbs of the body, the simple elemental metals like gold or silver are too weak for the mechanical stresses. On the other hand, the alloys that are sufficiently strong are chemically attacked by the fluids of the body and this leads to unpleasant and sometimes dangerous reactions at the fracture site.

Dr. Wheat suggested to Dr. Venable that he try Vitallium screws in the dogs being used for the experiments in this research. Vitallium proved to be just "what the doctor ordered" and what he and thousands of his colleagues continued to order in increasing amounts from that time on. Plates, nails and screws soon became a standard line and many other parts have been added to the catalogue since. By 1937 the preliminary cases had been under observation sufficiently long to justify all the hopes for Vitallium in orthopedic applications, and it was announced commercially to the surgical profession by means of advertising in the orthopedic surgical journals.

All these things, dies for plastic and ceramic molds, finger rings, orthopedic appliances and other incidental items were cast out of Vitallium by Austenal's techniques. The possibilities of other applications were realized, but Austenal's expand-

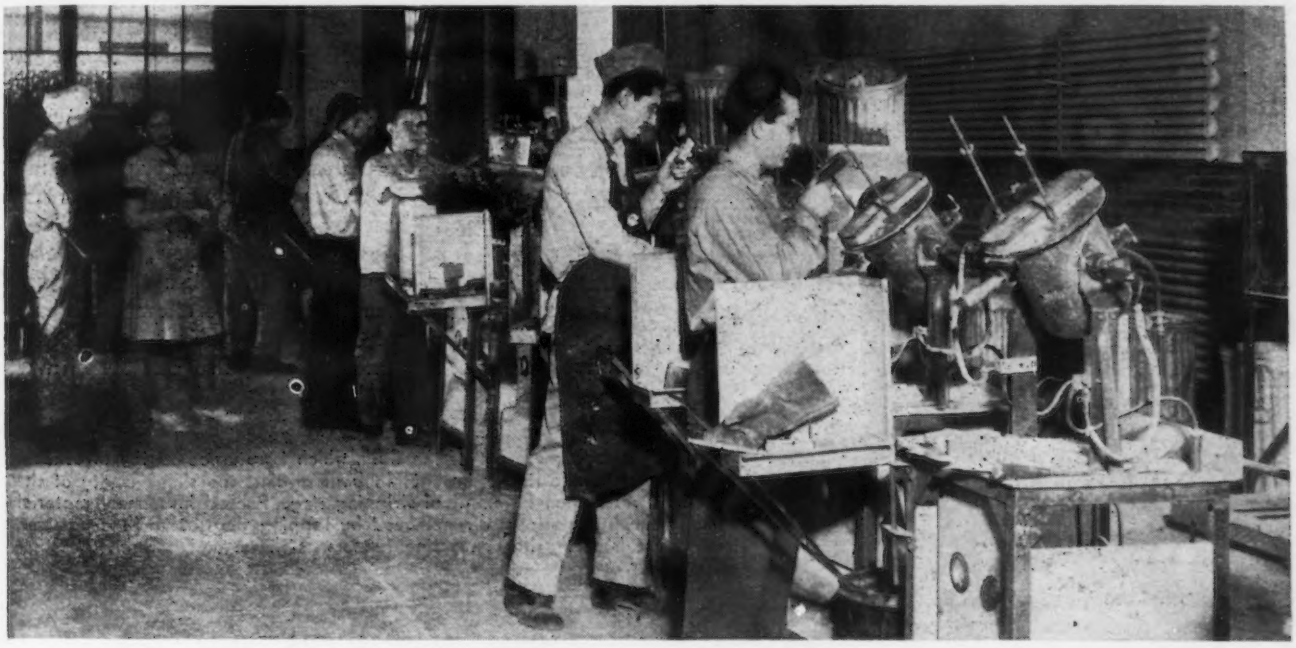


FIG. 6—Battery of 12 small tilting electric casting machines in which the Vitallium alloy is melted at 2900 deg. F. Red hot flasks are removed by tongs from the baking ovens, just out of sight to the left and are clamped to the top of the furnaces which are a special Austenal patented design. By rocking the furnace 180 deg. on its trunnions the entire charge (less than 2 lb.) is dumped into the flask. Air pressure assures a full mold and absence of blowholes. The third man from right has just poured a mold and brought it back to unloading position. Girl is handling optical pyrometer for checking heats.

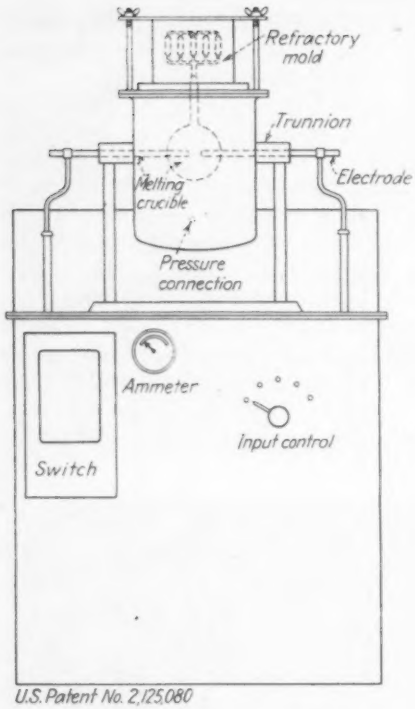
o o o



U.S. Patent No. 2,125,080

FIG. 7—Sketch of Austenal patented electric arc casting machine corresponding to the units shown in Fig. 6. The trunnions are pressure packed where the carbons pass through so as to maintain the air pressure when the melt is poured. This is done by tilting the crucible downward.

ing demand for its own products absorbed the major part of its attention. However, alloys such as Colmonoy, Stellite and stainless steels were cast for varied applications.

Then came the war, with its great demand for planes and more planes. Long before Pearl Harbor and the entry of the United States into the war, industry was overtaxed and many bottlenecks had already appeared. None were more serious in the beginning than machine tool shortages, and manufacturers bestirred themselves to cope with this situation.

A casting process that can produce parts of intricate design, that are of accurate dimensions and have smooth surfaces, requiring little if any machining or finishing operations, in the field of high melting point alloys, holds similarly attractive possibilities that die castings do in the lower melting range of metals and alloys.

Now the various threads of this story weave together in a completed pattern of accomplishment.

The manufacturers of General Electric turbosuperchargers for war planes soon were overwhelmed by the demand and looked about eagerly for help. Metallurgists in G.E.'s research laboratories had developed several alloys that were too refractory to forge and machine readily, but which had the properties required for the severe dynamic and thermal stresses to which the bucket vanes of the gas turbine of the supercharger are subjected. These buckets parts are small, require accurate dimensions and have intricate shapes and sections.

Vitallium in Aircraft

Austenal was approached by W. E. Ruder of General Electric's research laboratory. Sample castings and test bars were cast from these G.E. alloys and others, including Vitallium. Tests revealed that certain of the alloys tried were superior in the cast condition, and X-rays revealed the soundness of these materials as cast. Compared with other cast materials Vitallium showed excellent hot strength under test and incidentally has good corrosion resistant properties against hot products of combustion from highly leaded fuels.

This material was approved by the Army Air Forces and General Electric and two Austenal plants were set up to produce Vitallium buckets. Although the company had moved into expanded quarters in July, 1941, to take care of this business, this space was soon taxed to capacity and by the following January space was taken in an adjoining building. Meanwhile other manufacturers were licensed to use the same techniques and were given technical advice as to procedures and equipment as some of the controls are quite critical if best results are to be obtained. The companies are subcontractors under the producers of the superchargers, chiefly General Electric and their licensees, Ford Motor Co. and Allis-Chalmers Mfg. Co., and include the Haynes Stellite Co., which also supplies the basic alloy material to all producers of Vitallium buckets.

Views showing the step-by-step process of producing supercharger buckets in the Austenal New York plant are shown in the accompanying photographs. The initial steps differ somewhat from those used in making Vitallium dentures, mentioned earlier in the article. A master pattern must be produced in metal such as brass or steel by conventional machining methods. From this master, a split die or mold is made of bismuth metal sufficiently oversize to allow for a calculated amount of shrinkage. To some extent this is also offset by invest-

FIG. 8—Stripping the investment out of the flask, which is returned to the investment department. The pneumatic ram is brought to bear against the shrink cavity of the gate while the flask rests upon an elliptical stripping ring. Packed investment material (left) surrounding the buckets is readily removed by tapping the gate with a hammer, leaving the buckets with connecting runners as shown at the right.

FIG. 9—Vitallium buckets being sawed apart from the connecting runners with this abrasive cut-off machine. Final operation is to tumble and blast the buckets to remove the last vestiges of the investment material and obtain the surface finish desired.

ment expansion due to heating of the flasks. Into the metal mold, wax is injected under pressure.

Investment Molding

The next step consists of embedding this wax in a suitable liquid mold material called an investment. The binder for these investments is usually ethyl silicate, an organic chemical developed by Carbide and Carbon Chemicals Corp. On standing, this fluid silicate is converted to solid silica. Joggling the flasks removes air and settles the refractory material about the wax pattern, which may be of intricate shape, as in the case of 20 buckets hooked together with sprues, runners and a central gate. By inverting the flasks on a steam table, the wax runs out, leaving the cavity undisturbed. Vibrating or tapping a wood pattern from a sand mold, on the other hand, always enlarges the mold somewhat and destroys any initial accuracy.

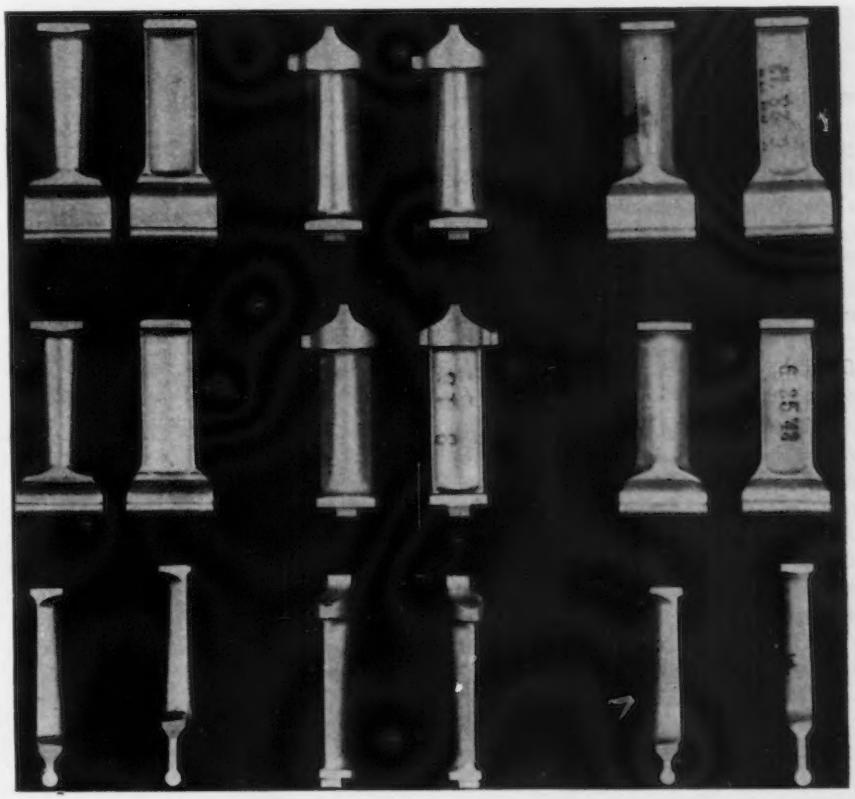
Air drying of the flasks takes place in racks, after which they are pushed through a baking oven under constantly rising temperature. The molds are poured while hot (2000-2200 deg. F.) to assure fluidity of the Vitallium metal which is cast under pressure at a temperature well above the melting point of this material. This also assures proper filling out of the mold and sound castings. It will be noted that small carbon arc furnaces (see cross-sectional view) are employed and that pouring is effected by clamping the red-hot flask to the top of the furnace and then inverting it. Because of the hardness of the baked investment, stripping from the flask has to be done by power. Most of the investment clinging to the casting is dislodged by tapping with a hammer. The rest comes off the work when the buckets are being separated from the sprues and runners by abrasive cut-off wheels or during tumbling.

Future Applications Seen

With the cessation of hostilities, much of this war business will cease abruptly, but manufacturers, engineers, executives, etc., have seen enough of precision casting to realize its wider application in times of peace and when competition for business becomes the normal condition again, many industries will find themselves either using or making precision castings of old and new alloys, making parts that would be virtually impossible by forging and machining methods. The designing engineer will not be limited by the restrictions imposed by established machining practices. Unconventional or complicated shapes,

o o o

FIG. 10—Turbosupercharger buckets, dovetail and welded types, made from Vitallium by the precision casting process.



including complicated internal coring, can be cast that would be the despair of any machine shop.

The micro-cast technique has made it possible to produce castings usually weighing less than a pound in a variety of ferrous and non-ferrous alloys which approach the accuracy of die castings. Improvements in the technique of making wax patterns make it possible to obtain uniform results with very little variation from pattern to pattern. It is also possible to compensate for all metal shrinkage by overexpanding the refractory investment molds. In actual practice, however, it is usually not practical to elevate the temperature of the refractory mold in order to compensate for metal shrinkage. Shrinkage allowances are made at present in the master patterns so that the wax patterns produced from the resulting molds are somewhat larger than the finished casting.

Castings weighing up to 1 oz. and requiring a tolerance of 0.005 to 0.010 in. are being produced on a mass production basis at present. On certain parts of these castings, tolerances of 0.003 in. have been successfully maintained. At present, work is under way on castings as large as 5 lb., and it is safe to predict that the tolerances that can be maintained will be far closer than can be maintained by ordinary foundry practice.

For alloys difficult to forge and machine this technique is virtually a must, if their use is not to be foregone. With more conventional alloys, readily machinable, the merits of each case must be judged individually.

This new type of casting is a permanent contribution to the art of founding and many possibilities as yet untouched await unfoldment under its future development.

The government has the whole subject of precision castings under organized research study through the Office of Research & Development of the WPB, Washington. The War Metallurgy Committee is participating in the study of applications to other war products than turbine buckets.

Anodic Films on German Aluminum Alloys

SAMPLES of anodically-treated aluminum alloy parts have been taken from several German aircraft, chiefly from the airframes, according to the British Ministry of Aircraft Production. These have been examined for type and nature of the anodic films. In all, 19 parts have been examined. The names of the castings, the aircraft from which they were taken, the appearance of the anodic films, and the corresponding type of British material, are indicated in the accompanying table. Scratch tests and bend tests showed that the films were adherent, hard and brittle. The film on the cock body was very hard.

Chemical Tests. — Chemical tests were made on samples of the films after removal of the films by scraping. Sulphate was detected in all the films except that on the cock body. Chromium was detected in all the yellow films, but not in the buff-colored film on the cock body. It is evident that all the films except that on the cock body had been produced in sulphuric acid baths, and that the yellow films had been sealed in dichromate solutions.

Observations on film thickness were made by removal of the films by chemical means and by microscopic examination of transverse sections. A boiling solution of phosphoric and chromic acids was used, as recommended by J. D. Edwards (A.S.T.M. Preprint No. 19, 1940), since sealed films are not readily removed by cathodic treatment in hot chromic acid solution. The thickness of the films was calculated from the loss in weight on stripping. In the calculation of film thickness, the density of the film was assumed to be 2.8. It is known, however, that the density of anodic films on aluminum alloys varies with the conditions during formation of the film, etc., and that the values obtained in this way vary by ± 25 per cent from the actual values of film thickness. Transverse sections of the samples were prepared, and the anodic films were examined microscopically. The examination revealed no unusual feature. The microscopical method of observing the thickness of anodic films on aluminum is generally considered to be the best.

The anodic film on the cock body appeared not to have been sealed. The film was very hard, was 15 microns thick, and appeared to have been produced by the "Eloxal GX" process; *i.e.*, by D.C. treatment in an oxalic acid bath. As the plug (steel) of the cock seats directly upon the light alloy body, a hard anodic film on the latter should be of advantage in this application. Part of the cock body was cleaned and retreated in an 8 per cent oxalic acid bath at 60 volts, 18 to 20 deg. C., 60 min. The new film resembled the original one, but was 22 microns thick. The anodic films on the other items examined had all been produced on sulphuric acid electrolytes. It is therefore most probable that the D.C. sulphuric process known in Germany as the "Eloxal G.S." process had been used. Most of these films had been sealed by treatment in dichromate solutions to provide increased efficiency of protection. The thicknesses of the films, 5 to 15 microns, are not unusual for films produced by this method. The depth of color of the yellow films appeared to be roughly proportional to the thickness of the films. The films on the external surfaces of the oxygen bottles had not been sealed by dichromate treatment, but had been dyed blue. The film on the gun mounting ring casting was of dark gray color, due to the aluminum alloy containing a high percentage of silicon.

Anodic treatment of aluminum aircraft parts in Germany had been described in an article in "Dornier Post." The conditions of operation are 15 to 20 amp. per sq. ft., 11 to 22 volts, 16 to 24 deg. C., and sulphate of aluminum content of bath not greater than 45 grams per litre. Hot potassium dichromate solution (90 to 95 deg. C.) is used to seal the films.

Machining Plastics

. . . Because of the nature of the material, cutting speeds for machining plastics are generally higher than for metals. Different results are obtained with the various grades of plastics. Some materials can be finished smoothly with a bronze cutting tool. On the other hand, sometimes abrasive fillers are present in the material which will dull even the usual high speed steel cutting tools and necessitate the use of a hard cutting tip such as tungsten carbide. In this article the author summarizes current practice in machining plastics.*

o o o

By W. S. LOW, Jr.
United Industrial Products, Inc., Elizabeth, N. J.

o o o

TECHNOLOGICAL developments have greatly influenced the trends in the plastic industry. New materials, equipment, methods and applications indicate continued growth and expansion. Plastics are not crystalline in nature; they respond differently to the action of cutting tools than does metal and therefore a different technique must be applied. For example, in turning cast resins a bronze tool bit is used for small production and will not require dressing for the first 100 or 150 cuts. However, for large production high speed steel tools are preferred on all types of operations.

In the preparation of bronze or high speed steel tools a carefully honed job is essential to smooth production pieces which frequently can move right from the production lathe or screw machine to the polishing operation without sanding or ashing. On the other hand, the first two or three cuts from a high speed steel tool may give unsatisfactory results because it is too sharp. Succeeding cuts, however, will prove to be smooth and free of pits until the tool is dull and begins to rub. Nearly all work is done dry, but coolants of the non-alkaline type may be employed although rarely required.

In turning, tools are sharpened very much as for brass work. There should be plenty of clearance, 10 to 20 deg., and a slightly negative or zero rake is desirable. The tool should be set at right angles to or 1 or 2 deg. above the center of the material and cutting edges should be in condition to produce long ribbon shavings. Special grades of tool materials are not required, although many hard bronze tools are employed and these can be filed without removal from the holders. Stellite, cemented carbide or high speed steel tools may be used when it is desired to get the longest possible runs without frequent delays for resharpening or resetting the equipment. The spindle speeds in turning operations range from about 450 to 6000 r.p.m. depending upon the specific work being done and the diameter of the material, and should be regulated to a surface speed of 600 ft. per min.

Machining Laminated Plastics

In machining laminated plastics and vulcanized fibers practically the same rules apply as in machining brass and it is advisable to use the highest possible speeds and to keep tools sharp. Slow speeds will not only curtail production, but will make tools dull rapidly. Cemented carbide tool tips such as Carboloy are especially recommended for turning and boring as they permit higher speeds and reduce grinding.

A sharp tool, plenty of clearance (at least 30 deg.) will contribute greatly to the successful machining of laminated plastics and vulcanized fibers. Extremely hard and tough, and slightly elastic, these materials are inclined to impinge against the back of the tool generating heat and dulling edges. Sufficient clearance eliminates the abrasive rubbing action characteristic of these materials.

Laminated plastic and vulcanized fiber tubes, rods and washers can be successfully machined in automatics and hand screw machines. It is well to note that tubes are not always exactly concentric, and if concentricity is required, it is advisable to specify the tubes a little smaller on the inside or use rod stock and drill concentric. It occasionally happens that rods turned from sheet stock will work where molded rods are not found practical. The recommended cutting feeds on automatics are as follows:

Feeds In. Per Rev.	
Drilling	0.007 to 0.015
Turning	0.010 to 0.015
Cutting off...	0.002 to 0.005
Forming	0.002 to 0.003

Water hardened steel should be used for form tools due to increased hardness and lengths of runs between grinds. Cut-off tools with carbide tips will be found well worth while. The spindle speeds recommended for various stock sizes are:

Hand screw machines	
1 in. diam. and over	800 to 1000 r.p.m.
Under 1 in.....	1500 to 2000 r.p.m.
Automatic machines	
Larger than ⅝ in. diam.	2500 r.p.m.
7/16 to ⅝ in.	3600 r.p.m
⅛ in. and less.....	5000 r.p.m

Satisfactory results may be obtained in drilling holes up to 3/16 in. diameter by using the regular standard high speed drills with a slightly

*Excerpt from material appearing in the 1943 edition of the Plastics Catalog by permission of the publisher, Plastics Catalog Corp.

negative rake ground on the cutting lip. It is advisable to back out the drill often to avoid buring since very high speeds are advocated. Speeds ranging from 2800 to 12,000 r.p.m. are used for small holes, or 100 to 300 ft. per min., but when the material has high abrasive qualities, the speed may be reduced to approximately 75 ft. per min. A thin jet of compressed air directed as near the hole as possible and directly on the drill hole helps to keep it cool.

Specially designed drills for plastics are available and should always be used in drilling holes larger than 3/16 in. diameter. These drills have highly polished flutes, maximum chip clearance, slow helix for pierced holes, fast helix for blind holes with a 55 deg. point ground for thin sections and a 90 deg. point for thick sections. The method of grinding drills for plastics includes a slight radius at the end of the lip which helps to maintain hole size. However, due to the abrasive action of some materials, drills sometime cut as much as 0.003 undersize, necessitating frequent inspection.

When drilling methyl methacrylates use a drill with a flute angle of 17 deg. with a lip angle of approximately 70 deg. and lip clearance angle approximately 4 to 8 deg. The lands should be polished one-fourth the width of the heel. Drill lubricants aid in chip removal, carry away heat and improve the finish. The best lubricant for drilling methyl methacrylate resin is a warm, mild soap solution, although oil performs satisfactorily but requires an extra cleaning operation.

High speed drills are recommended or drilling used at highest speed possible without burning the drill. A ¼ in. drill should be run at least 2500 r.p.m. for best results and 10,000 r.p.m. would not be excesive for a No. 60 drill. Dubbing the lip of the drill and giving it plenty of clearance will let it cut freely and will tend to prevent any splitting and grabbing. Drills should not be forced and if kept sharp only slight pressure will be necessary.

In drilling, these materials have a tendency to bind on the drill and close in when the drill is removed. It is advisable, therefore, where tolerances are close to use a drill a few thousandths larger than the size wanted. It is well to try out the material before ordering jigs to assure correct size of hole since jigs should be made with a plate beneath the piece to prevent breaking out as the drill passes through. The special drills made by most manufacturers especially for plastic materials, have wider clearance grooves and will give much better results than standard metal cutting drills.

Reaming

Although it is sometimes necessary, reaming plastics is not recommended, it is best accomplished by the use of expansion reamers with self-centering floating holders. A speed of not over 50 to 100 r.p.m. is used with a very fast feed. Close inspection is necessary on all reaming operations due to the abrasives in the materials rapidly dulling the sharp cutting edges of the reamer, causing a binding and squeaking condition that is likely to cause breakage as well as producing undersize holes. It is often advisable to drill the hole to within 0.001 in. in size and burnish it to the required size by the use of a very highly polished hardened rod pushed through the hole.

Threaded Parts

Threads may be molded or tapped in almost all plastic materials and the American National Form of thread is preferable. Other threads, such as a rolled thread for fuses and lighting fixtures and a round profile thread for closures and bottle tops can be molded readily, but not tapped.

In general threads above ¼ in. diameter should be molded and smaller threads tapped. Tapped inserts are used where maximum strength or frequent use is required. Threads smaller than size No. 8 or finer than 36 threads per in. are not molded, because fine and shallow threads tend to fill with pure resin and are brittle. Molded threads are stronger and will hold their dimensions better than tapped threads which tend to swell where the resin has been cut. Do not retap a molded thread.

Since the shrinkage of the compound affects the diameter and lead of a molded thread, long molded threads will fit mating parts of the same plastic better than metal mating parts because the two molded parts will shrink the same amount. Tolerances of plus or minus 0.005 in. may be held on diameters up to 2 in. on molded threads, but to assure best dimensional stability, parts with molded threads should be baked. Molded threads should begin and end abruptly. A hole extending below a molded thread should be smaller than the root diameter of the thread, and tapered if possible. If the member forming the thread is stationary in the mold, provisions must be made to unscrew the molded parts.

Tapered or pipe threads are not molded unless unusually heavy sections are to be joined because the pressure created by the taper will crack the molded part. For closure or liquid tight threaded sections, allow at least one complete turn, and more if possible.

Threaded holes for tapped threads or for drive screws should be slightly countersunk to prevent a ridge around the hole which would keep the screw from being seated. In every design for threaded parts, consideration must be given to the parts of the mold that are to form the thread. The part designer may facilitate molding and decrease maintenance by providing proper radii fillets and grooves in molded parts.

Tapping

Threads can be tapped as fine as 56 threads per in., but tap threads over ¼ in. in diameter should not be tapped. Mineral filled compounds are brittle and are difficult to tap without chipping, and fabric filled materials tap readily but the exposed cut surface will tend to swell when moisture is absorbed. Tapped threads can be held to a class 2 fit on low moisture absorbing materials on diameters under ¼ in. When molded or drilled holes are to be tapped, allow for an adequate cross-section and make them small but adequate (taps will clog on long holes) and tap through the hole if possible.

Regular standard taps may be used for tapping cast resins, but the ground high speed steel taps have proven more satisfactory and chrome plated taps with highly polished flutes are recommended for long production runs. Very little rake and plenty of clearance are desired as some of the highly abrasive materials occasionally cause the taps to cut very close to size and binding is often experienced in backing out. This condition will be improved if clearance is ground on the sides of the threads. Three flutes instead of four give better results and longer tap life.

A speed range of 40 ft. per min. has been recommended for 0.736 in. taps and 54 ft. per min. for 0.0590 in. taps. Water has proven more efficient than oil or kerosene, but dry tapping is even better for the least wear. Due to the abrasive action of some cast resins the taps are inclined to cut very close to size and as wear is experienced the holes will become undersize. Therefore, close inspection is advised where tolerances are low. Most fabricators of plastics prefer to use taps that are oversize to the high limit, thereby greatly decreasing the possibility of rejected parts due to undersize threads.

In tapping laminated plastics and vulcanized fibers, high speed taps

0.002 to 0.005 in. oversize are recommended and a little oil will help. As many as 3000 holes can be threaded in ¼ in. material with a 10/32 tap without sharpening. A drill suitable for 75 per cent full thread will facilitate tapping and cut down tap breakage and a slight chamfer around the edge of the hole before tapping will prevent uplift. For larger holes over 1¼ or 1½ in. collapsible taps are available which step up production and give satisfactory results.

External Threads

External threads may be molded in split halves. This will make the thread out of round by 0.005 to 0.015 in. and will leave a slight ridge across the threads, however, it provides a fairly serviceable thread and is cheaper to mold.

External threads may be produced by the use of self-opening dies with high speed steel chasers that extend out in front, having less chamfer than the standard chasers. Circular chasers give much longer service than the standard chasers. Plenty of clearance is essential and dies should be kept sharp at all times. Thread cutting in lathes is accomplished in exactly the same manner as in brass or steel. The fine threads sometimes required in radio coil forms, for example, can be cut to advantage with a V tool on small bench lathes equipped with a threading attachment and an expanding collet. Where only a few pieces are to be threaded, the work can be done in an engine lathe with a V tool. It may be necessary, however, to make several cuts which should not start more than 0.007 to 0.010 in. deep and decrease as the cut deepens.

Thread milling machines are excellent for milling medium or large diameter threads, as the hobs or cutters used in these machines are very accurately ground to size and to the number of threads per in. The hobs are made for the desired length of the threads and are usually made of high speed steel to stand up under the high speeds desired in production. By the use of cams installed in the machines one complete revolution of the piece is all that is required to produce a smooth milled thread that can be held to very close tolerances.

When threading or tapping methacrylates to fit a metal bolt or nut, allowance should be made for the difference in the coefficient of thermal expansion of the two materials. A slight increase over normal metal clearance is usually ample. Either hand or machine tools may be employed for threading or tapping and the material also works well in lathes or automatic screw machines where standard taps can be used without modification. In cutting threads the tap or die should be operated at a speed of about 25 per cent slower than for brass or cellulose plastics. Higher speeds develop frictional heat and gumming of chips and taps should be backed out frequently to prevent jamming. In hand tapping small holes 3/16 in. or less, it is not necessary to use a lubricant if care is exercised. On larger holes, however, a lubricant such as a mild soap solution is recommended for drilling. For machine tapping or threading, the work should be flooded with lubricant and in hand tapping lubrication will assist in producing a smooth accurate thread.

Milling

Milling operations may be accomplished by the use of any standard milling machines using standard cutters. However, the carbide tipped variety is especially recommended for long production runs due to the increased speed available and valuable time saved with a corresponding reduction in the machining cost per part. Parts may be held in any standard milling vise or chuck clamped down to the table, or held in specially designed jigs or fixtures. The cutting speed is approximately 400 ft. per min. although where only a very light cut is necessary speed may be greatly increased. The use of carbide tipped cutters permits increasing this speed to about 1000 ft. per min. Slow feeds are beneficial for producing smooth finishes. Milling cutters must be kept extremely sharp at all times; honing the teeth to a very smooth cutting edge pays big dividends in smooth cuts and time saved in finishing.

Abrasive cut-off wheels are most widely used and they involve a high speed spindle to which is fastened the abrasive disk, mounted on a swinging arm on the other end of which is the motor. The weight of the motor acts as counterbalance and permits the operator to feed the wheel down into the material. A flood of water on the material prevents scorching and produces a smooth easily polished cut with a minimum of waste.

Sawing

Sawing is done at 1200 to 1300 ft. per min. or above and best finished results are obtained on a band saw with 14 or 18 teeth per inch. On a jig saw the generally accepted blade is a No. 3 jewelers blade with 22 teeth to the inch for intricate work, and a No. 4 or No. 5 blade for production or for stacked work.

Thin methyl methacrylate sections can be individually sawed without a lubricant and it is also unnecessary to lubricate thick pieces if they are fed slowly. However, a lubricant will reduce or eliminate chipping, produce cleaner cuts and overcome the tendency of the saw to bind or stick. In heavy cuts including stacks of thin sections, a lubricant will reduce smoke, but moderate smoking can be expected when the stock is cut without a coolant if the thickness is 3/16 in. or more. Water is the best lubricant, but oil can be used when rust is a factor. Oiled paper may be placed between the sheets to supply lubricant when sawing several pieces at one time and bar soap may also be employed as a lubricant.

Finishing Operations

Grease burnishing is a finishing process in which the barrel should be loaded with three parts pegs and two parts articles together with one pint of grease sawdust and one cup of precipitated chalk. This combination will diminish the grease film and shorten the operation. One hour before taking the parts out of the barrel, add another cup of precipitated chalk. This process requires from 3 to 12 hours at 30 r.p.m., depending upon the kind of articles placed in the barrel.

Dry tumbling is a finishing process using three parts pegs together with two parts articles, one cup of FFF pumice and 1½ cups of flushing or paraffin oil.

Wax finishing is produced by adding (while hot) 4 oz. of wax mixture to every 25 lb. of new pegs and about 2 oz. of mixture each time the pegs are treated thereafter. Pegs need to be treated only about once a day with continuous use and can be allowed to run until they have a slippery and glossy appearance. Wax should not be added while articles are in the barrel.

For polishing methyl methacrylates by the wax method, carnauba wax and beeswax dissolved in turpentine are poured over wooden pegs in the tumbling barrel.

A dull finish on laminated plastics can be obtained with sanding or grinding using a 220 grit and then buffing with standard cotton buffing wheels and tripoli or similar polishing compound. Grinding and sanding operations are both practical by means of belt or disk sanding and by centerless or plain grinding. In grinding it is advisable to use plenty of cutting compound, kerosene or water soluble

◆ ◆ ◆ Isothermal Quench Baths

By HAROLD J. BABCOCK
Research Engineer, Ajax Electric Co., Inc., Philadelphia

ONE factor that will always have to be considered in applying TTT curves is the maximum thickness of the piece to be treated. Fig. 8, reproduced from "Principles of Heat Treatment," by Dr. M. A. Grossman, will illustrate this point. These curves show the drop in hardness in water and brine quenched bars of SAE 3140 steel with increased diameter. If the center of the piece is not cooled fast enough, softer, high temperature structures are produced, as can be predicted from the isothermal transformation curve. Again, the importance of the *quench* must be emphasized. As in the quench and temper method, so also in the isothermal transformation method, success depends upon adequate quenching equipment. It is the rate of cooling that, fundamentally, determines the final structure.

With the conventional media, such as brine, water or oil, a bath possesses cooling rates as illustrated in the curves of Fig. 9. As previously stated, the rate of cooling in these fluids may be increased by lowering the temperature of the quench bath (refrigeration, as the extreme condition), agitation or circulation of the liquid or by spraying in jets against the surface of the piece.

It should be noted that in using oil as a quenching medium, the rate of cooling is increased by raising the temperature of the bath. This condition may be attributed to decrease in viscosity with rise in temperature thus increasing the fluidity of the oil. But the quenching temperatures used in isothermal procedure are, for the most part, above the boiling point of these liquids so that molten salt, lead, etc. must be used.

Molten Salt Baths Better

In commercial applications, molten salts have certain advantages over molten metals. They are just a little heavier than water so metals sink in the bath, whereas in lead, it is necessary to submerge the piece forcibly. It is possible to agitate a lead bath or to pump lead through a jet quench, but with molten salt for the bath the mechanical problem is much less. Lead adheres to the surface of the piece or remains in small apertures and is very difficult to remove. Salt adheres only as a uniform film that protects the steel from chemical action with the air during transfer of the piece and washes off completely in the final wash water. Lead becomes solid at 620 deg. F. whereas a nitrate-nitrite salt bath may be used at temperatures ranging from 350 deg. to 1100 deg. F.

One property of molten salt not widely recognized, is its cooling power at temperatures above 400 deg. F.

A study of the cooling rates of mineral oil and of molten salt has been made by Lueg and Pomp, (*Stahl und Eisen*, Vol. 61, pp. 266-272, 1941.) In Fig. 10 is shown the cooling power of several quenching oils at 68 deg. F. on a 0.47-in. steel ball. Fig. 11 shows the cooling power of molten salt at 482, 662, 842 and 1022 deg. F. respectively on a 0.47-in. steel ball. From this it can be seen that salt at 482 deg. F. has as great cooling power as the best quenching oil bath does at 68 deg. F. In mineral oils Nos. 1, 2 and 3 even at 68 deg. F., the cooling rate is retarded because the oil first vaporizes at the hot metal surface and then boils, thus preventing the surface of the piece from coming into intimate contact with the quenching bath liquid. Obviously, at a bath temperature of 482 deg. F., using oil is not practical. The molten salt does not vaporize or boil even at much higher temperatures and a smooth cooling curve is the result. In the higher temperature ranges, molten salt is a coolant capable, at a quench bath temperature of 660 deg. F., for example, of cooling a 0.47-in. diameter steel sphere at rates in excess of 230 deg. F. per sec. in a still salt bath.

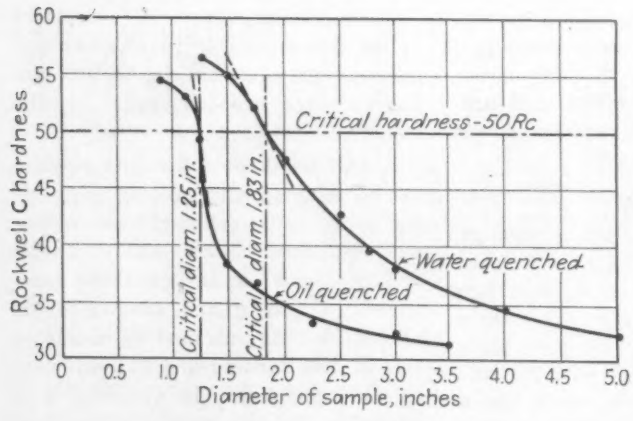

FIG. 8—Effect of increased thickness on hardenability of water and brine quenched SAE 3140 steel bars (Grossman)

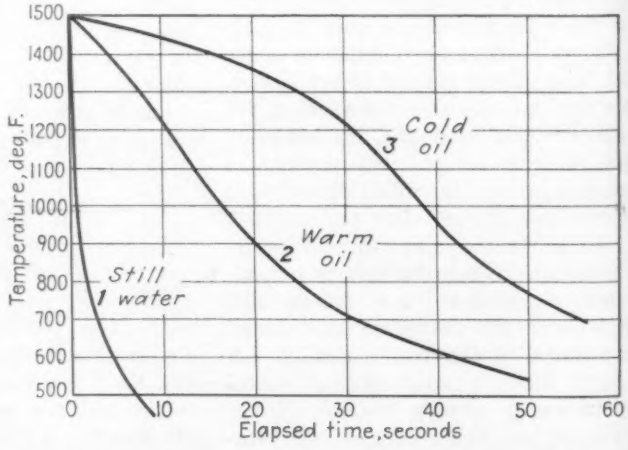

FIG. 9—Cooling rates of water and oil used to quench steel.

Applied to Commercial Practice

. . . Last week's discussion of isothermal transformation is concluded with a description of equipment and treatment used in industrial applications. The importance of the molten salt quench bath is stressed and comparisons with other quenching media presented.

Salt baths used for quenching steel are usually composed of chlorides of alkaline or alkaline-earth metals at temperatures ranging from 1000 to 1300 deg. F., or of nitrates and nitrites of alkali metals at temperatures ranging from 350 to 1100 deg. F. Such molten salts, at these temperatures, are fluids that flow almost as freely as water and are capable of being agitated by mechanical stirring devices or of being pumped through nozzles or apertures in fixtures to produce forced-jet quenching action.

Constant Quench Temperature Essential

In the commercial application of molten salt baths to the isothermal quench, success depends upon two well recognized functions of quenching equipment, particularly if used to treat any considerable weight of metal:

(1) The quenching medium must extract heat from the hot steel throughout the maximum cross-section at a rate equal to or greater than the critical quenching rate if complete through-hardening is to be obtained.

(2) If any considerable weight of metal is quenched, a great deal of heat is taken up by the quench bath. The temperature of this bath must be kept constant by extracting this heat from the quenching liquid by suitable cooling methods.

When molten salt is used as the quench liquid the cooling rate may be accelerated by means similar to those used with brine, water or oil. Moving the steel through the molten salt, violently agitating the molten salt or forcing it by suitable pumps through apertures to give a forced-jet quench, increases the rate of cooling just as in the low temperature liquid baths.

The cooling of molten salt to extract the heat liberated from the metal being quenched lends itself to much the same methods as applied to cooling other liquids such as brine and water, modified by the fact that molten salt freezes to a solid at temperatures close to 300 deg. F. It is not desirable to use water to cool molten salt since a leak or fracture in the cooling pipe or wall might bring it into direct contact with the hot salt thus causing an explosion.

A conventional salt bath commonly used in the range of temperature between 350 and 1300 deg. F. is usually designed for drawing steel. It is constructed with suitable heat insulating material and an insulated cover to retain heat in the bath so that it may be operated with minimum consumption of fuel or electric energy. But such a bath design used for isothermal quenching of steel would be wholly unsuitable, especially if any quantity of metal is to be treated, since it is built to retain heat.

The commercial application of the isothermal procedure requires for its success a quench bath capable of absorbing and dissipating a large quantity of heat without an increase in the temperature of the molten salt.

A view of such a bath having the capacity to quench 300 lb. of steel per hr. is illustrated in Fig. 12. It will cool the steel from 1550 deg. F. to 650 deg. F. while maintaining the quench bath temperature within 5 deg. F. of 650 deg. F. Using the Ajax-Hultgren design[11], this bath heats the molten salt directly by current flowing through it. Two pairs of electrodes, each pair closely spaced, confines all current flow within the narrow space between the two electrodes. No heat is applied externally. An automatic temperature control instrument regulates the

FIG. 11—Cooling power of molten salts at 482, 662, 842, and 1022 deg. F. on a 0.47 in. steel ball. Initial temperatures were 1472 and 1742 deg. F. (Lueg and Pomp).

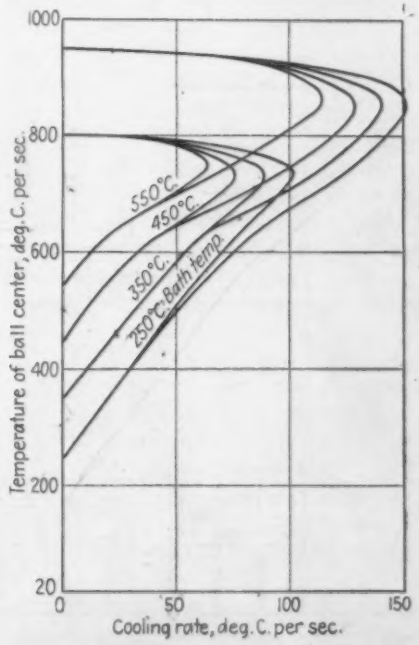

FIG. 12 — Isothermal high temperature salt bath quench with mechanical agitator and air cooled pot. To work successfully, a quench bath must be capable of absorbing and dissipating a large quantity of heat with no increase in temperature of the molten salt.

power imput to maintain the temperature of the salt up to the point set on the controls.

Surrounding the exterior of the bath is an air chamber in which a controllable volume of air is caused to flow. Whenever the temperature of the molten salt rises more than 1 deg. F. above the control setting, the cooling system is turned on and the bath temperature thus lowered. Such dual control for heating and cooling maintains bath temperatures within 5 deg. F. of any desired quenching point within the range of temperature for which the apparatus is designed to operate. In order to obtain maximum quenching speed, a motor-driven device maintains the molten salt in violent circulation or, in certain instances, a pump is used to force high pressure multi-jets of salt against the work held in fixtures.

Such design for an isothermal transformation quench bath, using molten salt, embodies the fundamental features that were emphasized previously. In Fig. 13 is shown an outline drawing of a group of electric, internally heated, salt bath furnaces in which such a bath is used, arranged for batch type treatment of small steel pieces. Twelve such installations are already in successful commercial operation.

The furnace arrangement illustrated by this drawing is for the heat treatment of SAE 4140 alloy steel. The pieces treated are parts of a shell fuse machined from annealed rod stock. These fuse parts, shown in Fig. 14, are threaded inside and out. Thus finished-machined, it is required that they be heat treated without distortion or quench cracks under such conditions that a hardness about 34 to 38 Rockwell C should be obtained together with the following minimum physical properties:

Yield point	130,000 lb. per. sq. in.
Tensile strength	145,000 lb. per. sq. in.
Elongation	13 per cent
Reduction in area	45 per cent

These pieces vary in section from a maximum of 0.5 in. in the large piece to a minimum of 0.004 in. in the small piece.

The conventional quench and temper method when applied to the large piece, particularly, presented a handling problem. Uniform results required practically an individual quench for each piece. The quench, even in oil, produced changes in dimensions, distortion and often quench cracks. If the pieces were dropped into the quench, mechanical damage to the threaded surface often resulted. In the quench and temper method, the pieces would have to be unloaded, quenching oil cleaned off and then reloaded into large capacity

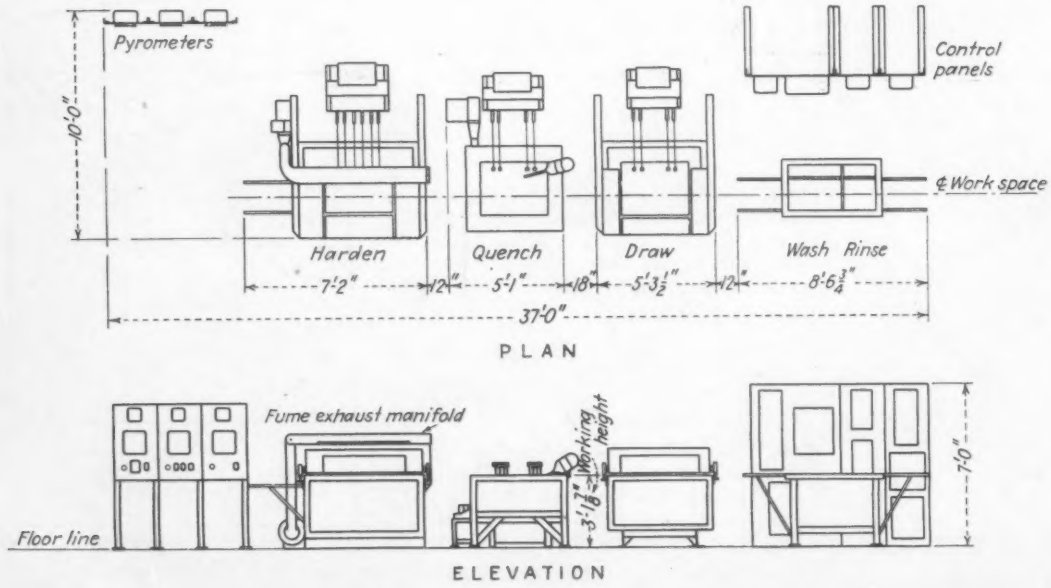

FIG. 13 — Layout of isothermal batch type hardening equipment for treatment of small steel pieces. Salt bath furnaces are internally heated.

racks for the draw or temper treatment, owing to the greatly increased time cycle required for drawing a martensitic steel.

Quench Cracks Eliminated

The salt bath would provide a high temperature furnace capable of heating at a rate more than four times as fast as a radiant type furnace. It assures uniform heating with total exclusion of atmosphere or effects of temperatures any higher than that of the liquid bath, that might affect the steel surface detrimentally. The use of a salt bath quench is known to eliminate quench cracks and minimize changes in dimension. (See Davenport and Bain[7].) Referring to Fig. 6 showing the time-temperature reaction (TTT) curve for SAE 4140 steel, it will be noted that between 625 and 725 deg. F. this steel will complete the transformation of its austenite to troostite in a period of about 100 sec. The structure will have a hardness of about 46 to 48 Rockwell C. The transformation of this steel is completed at the end of 1.66 min., but has too high hardness and too low elongation and reduction in area to meet specifications required for the fuse part. If it could be quenched at or above its critical rate in a bath held at 825 deg. F., a structure having the desired hardness and physical properties could theoretically be produced. But the maximum thickness is ½ in. The high temperature quench even if carried out in a pressure-jet quenching fixture could not cool the piece fast enough to be free from soft, high temperature products, with lower physical properties than required in the specifications.

However, as the writer interprets the work done by Greninger and Troiano[10] and Payson and Klein[13], the transformation reactions are completed in the isothermal quench bath. The product is always identified with the time and temperature used in this treatment. Then it follows that the physical properties of this transformation product may be modified as in any piece of hardened steel by transferring it to a bath at a higher temperature, appropriate for tempering this product.

In other words, if the steel is quenched in a salt bath at a temperature of 625 to 725 deg. F., kept in this bath not less than 1.66 min. and then transferred immediately to another salt bath held at a temperature of 950 to 1050 deg. F., a product having the desired properties should be obtained.

FIG. 14—These fuse parts were machined from annealed SAE 4140 rod stock and are threaded inside and out. Being finish-machined, their heat treatment should produce a hardness of 34 to 38 Rockwell C and a tensile strength of 145,000 lb. per sq. in. with no distortion or quench cracks. These results were obtained in the equipment shown in Fig. 13.

o o o

It was found that in a salt bath, operated at 1550 deg. F., the heavy piece of the fuse (½ in. section) could be austenitized in about 10 to 12 min. This heating time established the cycle of operation.

In Table 1, data are presented from a series of tests using 0.505-in. tensile test bars made from SAE 4140 annealed rod stock from which the fuse parts are made. The time in each step of the isothermal transformation treatment given the bars is held uniformly to 10 min. The data in these first four tests are included to show that at high quench bath temperatures, 10 min. did not allow time to complete transformation, and a mixture of low and high temperature structures was obtained. As a result, low hardness and low physical properties are obtained. Such product of transformation could be expected from the information shown in the TTT curve.

In tests Nos. 5 and 6, the same conditions were maintained except that the pieces were immediately transferred after 10 min. in the isothermal quench furnace to a draw bath at the higher temperatures shown in the table. In spite of the lower quench temperatures, the cooling rate of the quench bath was not high enough to cool the ½ in. section completely as required according to the TTT curve, less than 6 sec. to cool from 1385 to below 900 deg. F. Specimens were cut from No. 6 test pieces for microscopic examination (1) after the isothermal quench and (2) after the 10 minute draw. Photomicrographs in Figs. 15 and 16 (1000 diameters, nital etch) show the structures obtained. It is evident that the cooling curve passed through the "nose" of the "S" curve since lamellar products can be seen which accounts for the low physical properties obtained.

The cooling rate of the quench bath was increased by using the agitator, producing a violent, turbulent flow of the salt against the pieces being quenched. In tests 7, 8 and 9, the isothermal quench temperature was successfully lowered and the draw temperature set to obtain Rockwell C hardness values in the range 34 to 38 with a time of 10 min. in each bath.

Thus it was shown that by using the isothermal transformation method it was practical to reduce the whole series of operations to a cycle of 10 to 12 min. in each bath. Once the isothermal quench and draw temperatures are established for this type of steel, the operating conditions remain fixed except for slight adjustments required to meet variables due to chemistry, grain size, etc., as found in different lots received from the steel mills.

As this method is applied to the heat treatment of the fuse parts un-

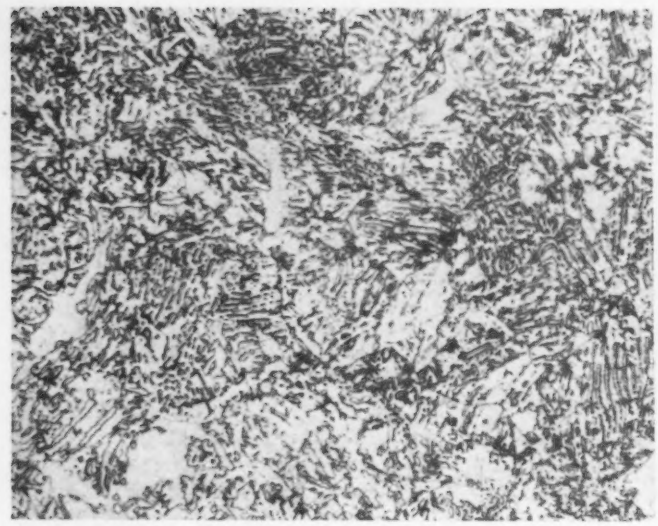

FIG. 15—Microstructure of ½-in. SAE 4140 steel, quenched 10 min. and then cooled. At 1000 diameters, nital etch.

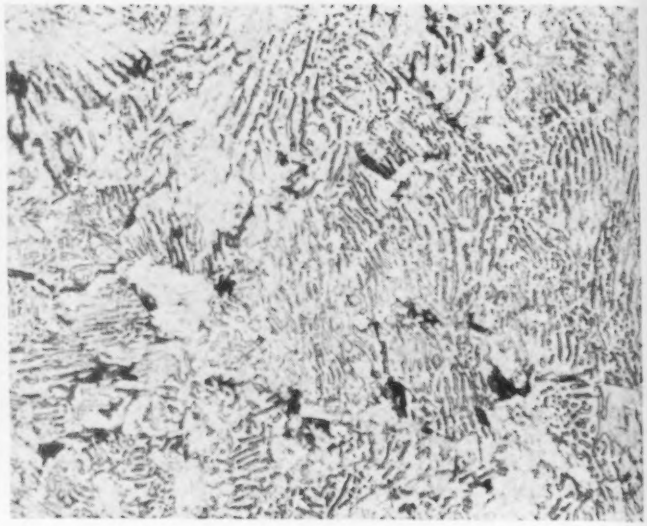

FIG. 16—Microstructure of ½-in. thick SAE 4140 steel, quenched and drawn 10 min. At 1000 diameters, nital etch. Low physical properties are due to the lamellar products seen in this photomicrograph and the one in Fig. 15.

der commercial conditions, the pieces held in suitable basket type racks are carried progressively through the hardening or austenitizing, the isothermal quench and the draw baths, hence onto the cooling racks and then into the wash and rinse tanks which remove the last traces of salt. (See Fig. 13.) They are carried through on the same fixture without any rehandling during the heat treatment.

It should be noted that by using salt baths in each of the three steps, the total time of treatment was reduced to between 40 and 48 min. per batch compared to 1.5 to 3 hr. by the conventional quench and temper methods. Quench cracks of even microscopic order were eliminated. Distortion was reduced to limits under 0.001 in.

In Fig. 17 is shown a typical commercial installation now in operation producing these fuse parts. With 12 such production lines in operation, it is interesting to note the results obtained under average production conditions. A typical chemical analysis of the SAE 4140 steel in one plant is as follows: 0.41 C, 0.90 Mn, 0.016 P, 0.031 S, 0.35 Si, 1.05 Cr, and 0.19 Mo.

The plant has heat treated over 20 different heats of steel (approximately 400 tons) and maintained the product within rigid specification limits without rejection of a single lot. Three lots selected at random show the following physical properties:

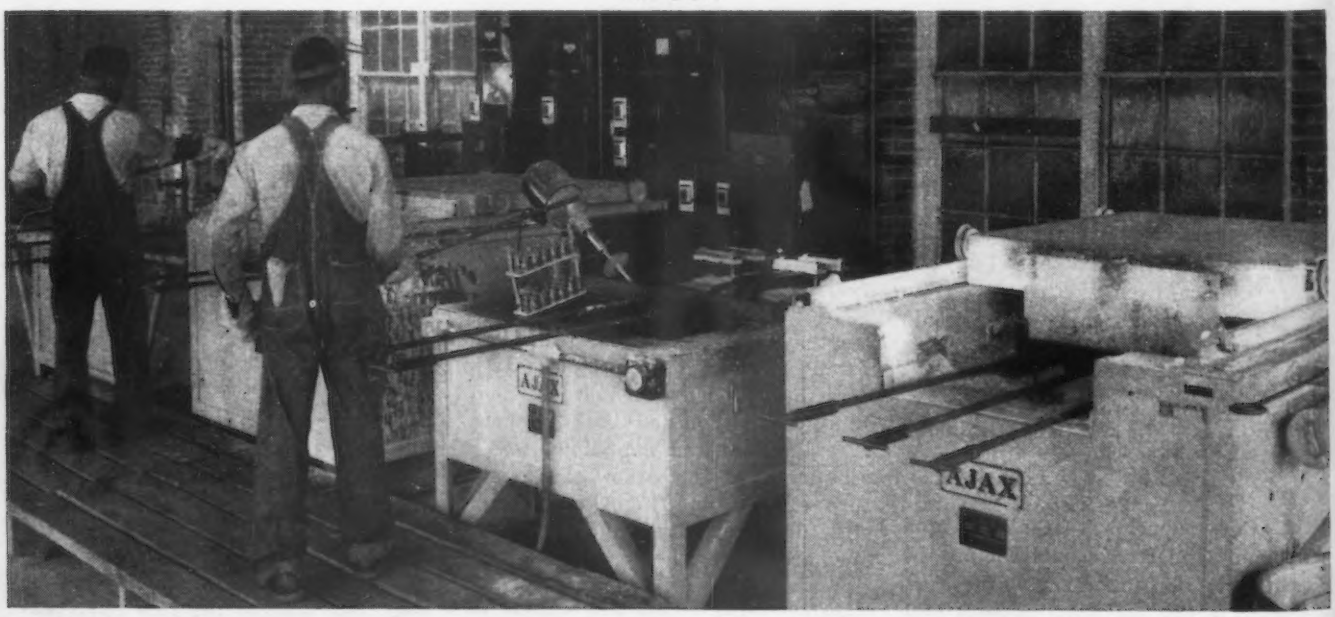
o o o

FIG. 17—Typical batch type isothermal production unit for the three-step salt bath process—neutral hardening, high temperature quench and draw.

Lot No.	Yield, Lb. Per Sq. In.	Tensile, Lb. Per Sq. In.	Reduction in Area, Per Cent	Elongation, Per Cent	R_c
143	168,500	180,000	57.5	17.0	35
144	172,000	183,000	57.7	16.5	35
145	176,000	189,000	57.5	16.5	35

Fig. 18 shows the structure (1000 diameters) obtained in lot 145. The reduction in area, the elongation and hardness combined with the high yield and tensile strength indicate clearly the tough, ductile properties imparted to the steel by this isothermal transformation method.

The commercial application just described in detail is typical of the way the TTT is used curve to predict the result that can be obtained in hardening steel. This application of the salt bath furnace used the



isothermal transformation method to obtain hardness of about 35 Rockwell C, in a structure of higher tensile strength (about 20,000 lb. per sq. in. higher) combined with higher ductility than can be obtained by the conventional method at the same hardness.

The TTT curve is equally valuable to determine how to avoid hardening. In Fig. 19 a yoke of SAE 52100 coiled rod stock is shown entering a salt bath at 1450 deg. F. for the austenizing treatment. If the yoke is "quenched" in a salt bath maintained at 1340 deg. F., the annealing cycle to produce a structure having hardness about 14 Rockwell C will be about 4 hr.[4] At the end of this time the yoke may be removed and cooled at any desired rate. Considerable time is saved in completing the operation compared to the typical annealing cycle in which the charge cools to low temperatures within the furnace.

Martensite Formation

Previously, it was pointed out that the quench and temper method, with its severe quench produced distortion and even cracks in the steel. This condition is due, in part at least, to the rate of formation of martensite. When martensite is formed in quenched steel, an increase in volume occurs, due to the lower specific gravity of this constituent, with the result that stresses are set up that often produce cracks in the piece. In the isothermal transformation method where hardness under 50 Rockwell C is desired, it has been seen how the formation of martensite is avoided entirely.

But the work done on the isothermal transformation of steel shows that the formation of martensite for austenite is not an isothermal reaction (Greninger and Troiano[10]), but a reaction depending for its completion on a decrease in temperature. Martensite forms immediately when the austenite cools to a certain temperature (below 590 deg. F.), and the reaction continues only as long as the austenite continues to cool. Then the TTT curves should show a way to lessen or even eliminate the stresses set up when full hardness is to be produced, as in Fig. 4 for example. Curve 3 for the 1.13 carbon shows that if this steel is cooled at or above its critical cooling rate to a temperature of 400 deg. F., the austenite does not begin to transform for a period of 50 min. Then, if the steel is quenched and held in a salt bath at 400 deg. F., it would be possible to bring the whole piece uniformally to this temperature. If this temperature equalization can be accomplished within less than 50 min., the structures of the steel would be austenitic. If the temperature of the piece is now lowered martensite will form. But as the transformation takes place at a slow cooling rate uniformly through the cross section, the soft austenite cushions the stresses set up when martensite if formed and minimum residual strains result in the product. It is understood, of course, that application of this procedure is limited by the thickness of the piece treated.

In Fig. 20 is shown a salt bath in which this method finds commercial application. Uniform hardening, combined with toughness in a spline shaft is thus obtained. The steel is shallow hardening. Since the maximum section is about 1½ in. thick, a radical quench is required to lower the temperature of the surface at a rate equal to or greater than its critical cooling rate. But it is essential to arrest the cooling of this surface at a temperature higher than that where the austenite transforms to martensite. In this type of steel this temperature is about 450 deg. F.

Under commercial conditions, an Ajax-Hultgren[11] electric salt bath, screw conveyor type is used for austenitizing in which the spline shaft is differentially heated by immersion up to the "collar" of the shaft. The pieces are transferred from this bath to a specially designed, automatically timed, collar-like water jet quench fixture. The time in this quench is held to between 10 and 12 sec. to obtain surface cooling at or above the critical rate. The spline shaft is then transferred immediately to a salt bath maintained at 450 deg. F.

This salt bath maintained at uniform temperature extracts the heat from the piece until the entire section is uniformly at bath temperature. When the piece is removed and cooled, the hardened area is uniformly at 49 to 51 Rockwell C up to the top of the shaft grading from there to 34 to 36 on the "collar." The piece is free from quench strains. Tests run on shafts so treated show that the tough structure so produced stands up against fatigue failure in accelerated life tests far better than those treated by the conventional quench and temper method.

FIG. 18 — Microstructure of ½-in. thick SAE 4140 steel produced by the isothermal method (12 min. cycle). Nital etch, at 1000 diameters.

Hardening A.P. Shot

Another commercial application is found in hardening armor piercing projectiles. Heat treated by the conventional quench and temper methods, they will shatter against the target more readily than the same projectile treated by the isothermal method. The shot is heated to about 1600 deg. F. for 30 min. and then immediately quenched into a molten salt bath held at 450 deg. F. The quench bath is designed with mechanical agitator which directs a stream of molten salt at the point of the projectile to assure maximum cooling rate at this vital part. At the end of 9 min. in the bath at 450 deg. F., it is removed and allowed to cool in the air. As it cools, the austenite transforms to martensite developing a structure with hardness about 59 to 61 Rockwell C on the nose of the shot.

Another commercial application is found in the treatment of carburized steel parts where a wear resistant

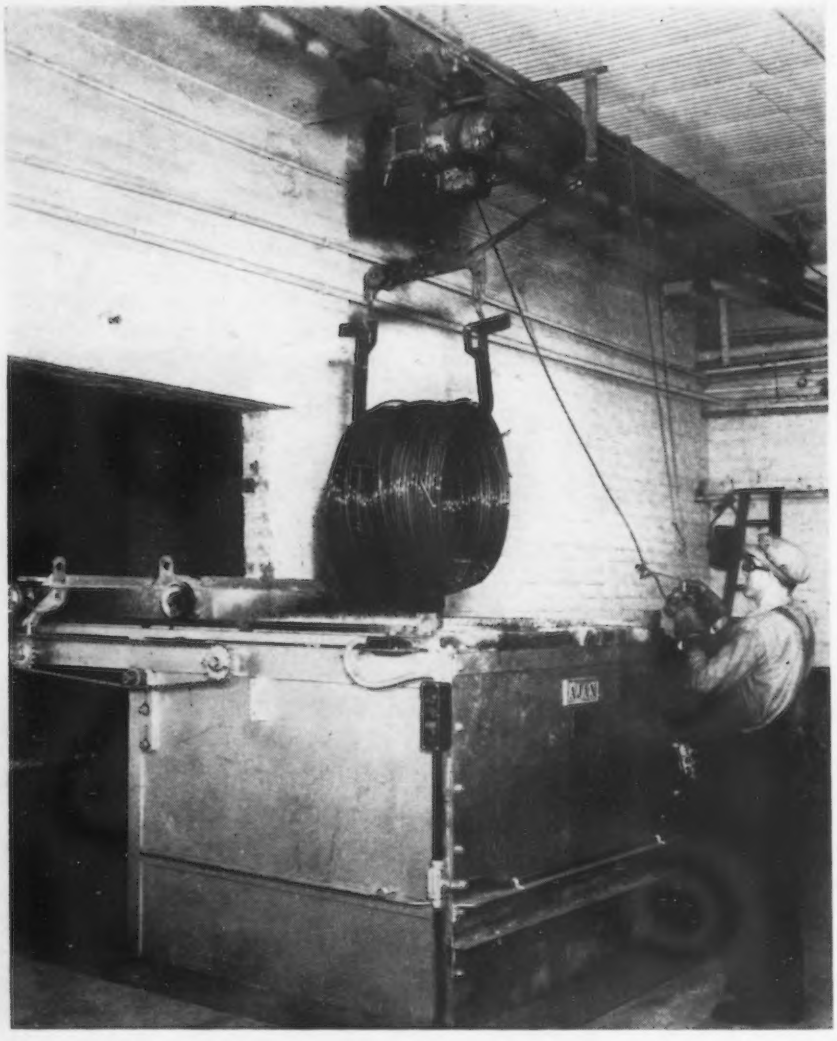


FIG. 19—Yoke of SAE 52100 coiled rod stock entering a salt bath at 1450 deg. F. for austenizing treatment.

surface subjected to high impact shock is required. These bolts of heavy caliber machine or "Tommy" guns are frequently distorted by the conventional quench and temper methods of treatment. If an electric salt bath is used with an activated carburizing salt, a uniform case and penetration are obtained. But it is not practical to quench into a bath of nitrate salts from a carburizing salt bath since an explosion would result. However, if the pieces from the carburizing bath are transferred to a bath of neutral salts, it will wash off the cyanide. The pieces may then be quenched from this wash bath into a nitrate bath without disturbance. When the machine gun bolts were thus treated, almost complete elimination of distortion was obtained and the case had a structure which was hard, tough and resistant to impact.

In this application the pieces, carried on racks, are immersed in a liquid carburizing bath at 1630 deg. F. for about 1¼ hr. to produce a 0.012 in. case, transferred to a neutral salt bath maintained at 1535 deg. F. and, from there directly to a molten salt quench bath at 475 deg. F. At the end of 1 hr. in this bath the racks are quenched in water wash tanks which removes this salt. The salt is completely removed even from the three small longitudinal holes and the one lateral hole by a wash in two tanks (for 1 min. in each tank). The hardness produced on the piece falls between 60 and 64 on the Rockwell D scale, (49 to 52 Rockwell C).

The quench and temper method previously used required a total time of 4.5 hr. compared to the isothermal method which requires 2.25 hr. The rehandling required was reduced from over 50 per cent of the pieces to under 2 per cent. Distortion over 0.001 in. was found in over 25 per cent of the pieces by the conventional method, requiring remachining the bore of the longitudinal holes. The isothermal method reduced this remachining to less than 1 per cent.

It is not intended to imply that the isothermal transformation method will replace or supersede the conventional quench and temperature procedure for all conditions. It is a procedure that enables the operator to predict the results he may expect to obtain where certain properties are desired which are not obtainable by conventional methods. It provides a method to produce a tougher, more ductile product than can be produced otherwise in steel at the same hardness. Like the older method, the analysis of the steel, its prior treatment and the maximum thickness of the piece influence the result that can be obtained. The highly valuable information now available in the TTT curves for various steels assists the heat treater to know where it is practical to apply the isothermal method. These curves, often called "S" curves, are not a curiosity that belongs in the metallurgical laboratory.

The commercial application of the isothermal transformation method places particular emphasis upon the rate of cooling provided in a quench bath using molten salt. The use of molten salt baths in this method of treatment provides the following desirable features:

(1) Uniform temperature throughout the entire bath area to assure uniform austenitizing or transformation desired.

(2) Minimum temperature gradient between the source of heat and the temperature at the center of the piece being heated to assure uniform grain size, and transformation product desired.

(3) Minimum oxidation or scaling of surface of the steel during heating or by contact with the atmosphere during the transfer required in the successive steps of the process to assure effective contact of the quenching medium with the metal surface.

(4) A quenching medium capable of cooling the steel at a high rate in a bath maintained at temperatures above 400 deg. F.

(5) A quenching medium that may readily be agitated or pumped through apertures in a fixture to assure a constant flow of the high temperature quenching fluid against all parts of the piece to obtain maximum rate of abstraction of heat.

(6) A quenching fluid which can be cooled by air blast and agitation to remove the heat brought in from the austenitizing bath by the pieces being quenched and prevent rise in temperature of this bath.

The isothermal procedures referred to in this article illustrate the wide field in which this method is finding applications. The development of the

* Bath violently agitated.

molten salt bath quench furnace described which is capable of dissipating the large quantity of heat brought into it from the high temperature austenitizing bath without variation in temperature, marks the transfer of the isothermal transformation method from a procedure of the metallurgical laboratory to that of the heat treat room. There are many units already in successful commercial operation, showing that the metallurgist and heat treater are quick to adapt to their needs new methods that offer to improve the properties of the steel they treat.

Forging 75-mm. Shell on C

MANY articles have been written about shell forging plants that either specialized in hot forging work previously or were able to purchase new forging equipment designed for shell work. This article concerns a plant which before Pearl Harbor was a wire product plant, making chiefly coat hangers, coiled springs for auto seats, furniture, etc. This company had no experience in hot die forging and was unable to buy new equipment, except a heating furnace. The hydraulic presses, pumps, breaking press and other pieces of equipment acquired for shell work are fugitives from a scrap pile, for all these pieces of equipment were purchased from scrap dealers all over the eastern United States.

In spite of the fact that this firm had had no previous forging experience and that most of its equipment

° ° °

By ALAN B. SALKELD

Research Engineer,
A.S.M.E. Special Research Committee on Forging of Steel Shells

° ° °

was improvised, the L. A. Young Spring and Wire Corp., Trenton, N. J., due to its excellent record of production, was awarded the Army-Navy "E" last July.

Billet Preparation

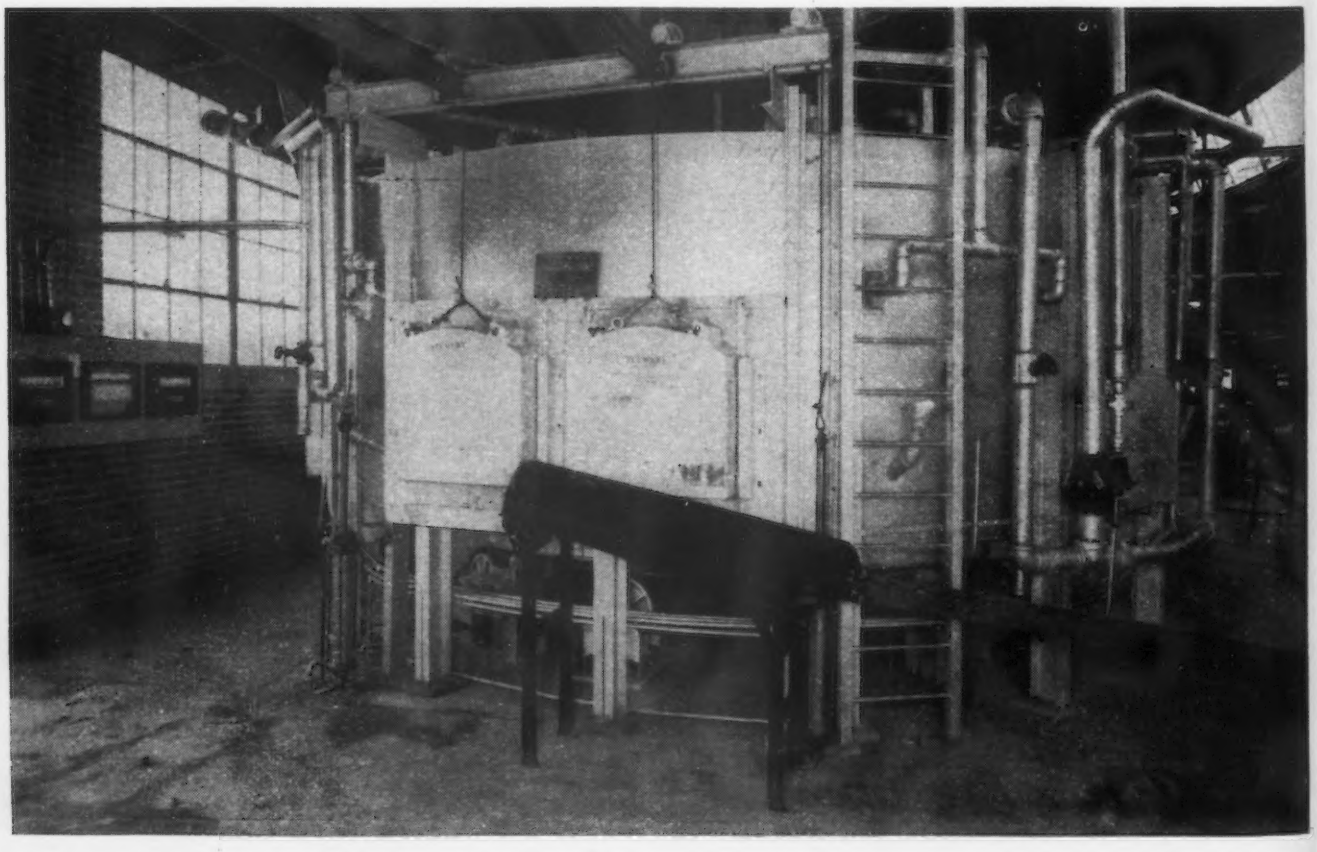
The 3⅛-in. round bar stock for forging shell is bought in lengths of 18 ft. 6 in., which make 27 slugs. From the outside storage yard they are rolled one at a time onto a gravity conveyor and transported inside the building. Inside, this conveyor acts as the nicking table, having a gage along one side with rests attached wherein the flame torch rests for nicking. A single flame oxy-acetylene hand torch is used to nick the bars about ⅜ in. deep for breaking.

After nicking a bar, it is rolled over onto an approach conveyor and pushed longitudinally into the breaker. The machine used for a slug breaker is a Toledo No. 57 mechanical shear which has been remodeled to act as a breaker. This shear is rated at 150 tons capacity and is amply strong enough to do the job.

The approach conveyor is anchored down at the farthest end from the breaker and is supported by two large compression coil springs 6 in. o.d. x 1 in. stock x 18 in. long; one is at the center and the other at the end near the breaker, Fig. 1. These springs cushion the jar from the bar while it is being broken.

As shown in the illustration, the

STEWART rotary heating furnace. The slugs are charged into the door at the left and discharged from the door at the right. Control of the three heating zones is by the recording potentiometers on wall at left.



Converted Rubber Presses

. . . High explosive shells are being produced by the pierce and draw method on rebuilt presses that were originally designed for much slower speed work in the rubber industry. With the exception of a rotary hearth furnace, all the equipment used by this wire products plant was rescued from the scrap heap.

o o o

bar stock is pushed into the breaker, and a pall drops into the nick, locating the nick directly over the breaking anvil. An inverted U holds the bar down and makes it possible to make the last break. After breaking, the slugs are then stored near the furnace, where they are handy for charging into the furnace.

The breaks are very even, thus providing uniformity of material in each shell forging slug. The slugs are 3⅛ in. diameter by 8.22 in. long and weigh 17 lb. 14 oz. There is on an average of 8 oz. lost by scale, thus making a finished forging weight of 17 lb. 6 oz.

It is necessary to operate the breaking shear only 16 hr. a day to keep the two forging lines operating 24 hr.

Heating Billets

The slugs are heated in a Stewart gas-fired rotary-hearth furnace, Fig. 2. This furnace has a hearth of 16 ft. diameter and holds 300 slugs at one time. The heating time is 1 hr. 15 min. per cycle.

The hot slugs are charged into and are drawn from the furnace by air-operated tongs which are supported by a cable attached to a manually operated monorail. They are placed upright on the hearth and are spaced 1 to 2 in. apart to provide even heating. Uneven heating will produce an eccentric forging. There is a firewall between the charging and discharge doors to help control the heat, which is controlled automatically in three separate zones. A recording potentiometer records the heat in the soaking zone where the temperature is kept at 2300 deg. F. The temperature of the slug leaving the furnace is about 2200 to 2230 deg. This heating furnace is capable of supplying hot slugs to both forging lines without interruptions or waiting for heated slugs.

The hot slug is carried from the furnace on a gravity conveyor and is deposited on a simple mechanical descaler composed of two grooved, motor-driven rolls, driven by a 1-hp. motor. After the scale is removed from the cylindrical part of the slug, it is grasped by a pair of tongs so that the end to be pierced is held against one of the rotating rolls, thus cleaning the scale from this end. It is essential that all scale be cleaned from the end that is to be pierced, otherwise the scale will be carried down into the cavity during the piercing operation and be imbedded in the wall of the shell, leaving a pitted cavity. Moreover, scale acts as an abrasive and will score punch tips and shorten the tool life. (Note slug being descaled in Fig. 3.) After descaling, the slug is ready to be pierced and is placed in the piercing die.

Piercing

The presses used for piercing (one press is used in each line) were used originally in the rubber industry at Akron, Ohio. These presses had been scrapped, and were found in a junk yard, covered with rust. The presses were purchased at scrap prices and were sent to Trenton for overhauling. Rubber presses are very slow acting presses, while the speed needed in shell piercing is about 7 in. per sec. (However, the writer has observed one-shot* presses in Canada that pierced shell at 36 in. per sec.

* *See also "One-Shot Method of Forging Shell,"* THE IRON AGE, *Feb. 26, 1942.*

These piercing presses, seen in Fig. 3, were built by Hydraulic Press Mfg. Co. and had a piston diameter of 22 in. and a 24 in. stroke. The hydraulic pressure is furnished by a weighted accumulator at 1250 lb. per sq. in., thus rating the piercing presses at 238 tons capacity. Three pumps are used to supply water to the hydraulic system. Two are in operation at all times and one is standing by to be put in operation in case of a breakdown. These pumps were bought from three different used machinery dealers. One is a Diane pump, driven by a 150-hp. motor, rated at 125 gal. per min.; one is a Blake pump, driven by a 250-hp. motor, furnishing 250 gal. per min., and the third is a Worthington pump, driven by a 150-hp. motor, delivering 200 gal. per min.

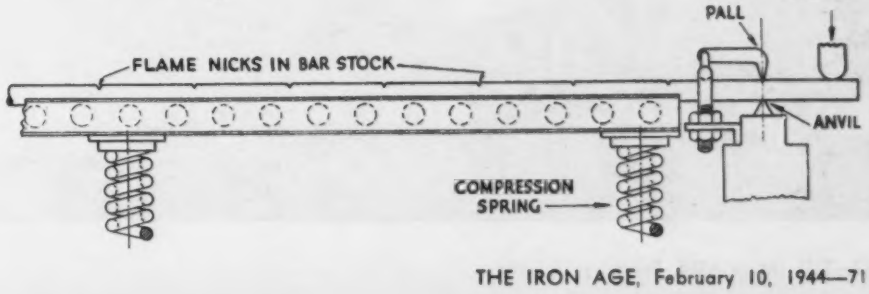
Originally the hydraulic pressure was 1600 lb. per sq. in., but due to the heavy water knock which broke the lines, experiments in piercing were made which proved 1250 lb. to be sufficient.

After it is pierced, the hot slug is ejected by a cross bar, which is attached to idler tie rods affixed to

o o o

ARRANGEMENT for supporting bars on approach conveyor to nicking press. The pawl permits positive location of nick directly over anvil and results in an even break and uniformity of stock in shell billets.

o o o



both right and left sides of the moving crosshead of the press. On the return stroke of the press, the forging is ejected from the die. The piercing punch is lubricated with Houghton's Hot Work No. 181 compound and is internally cooled by forcing water down the center of the punch in a tube and letting it flow up past this tube along the inner wall of the punch, flowing out at the top.

Piercing punches are made of Kloster DC-33 steel and last about 500 forgings before they need to be redressed. The punches are redressed about six or seven times, so that each punch can be used for piercing from 3500 to 4000 shells. The piercing die bushings were made of Hard Tem and last on an average of 5000 forgings (total life).

After ejecting the pierced slug from the die, it is grasped by a pair of hand tongs and turned, cavity down, over a rotating spader so that any scale which may have lodged in the cavity is spaded out before the drawing operation.

Drawing

The draw presses (one in each line) were built by Charles F. Elmes Engineering Works and, like the piercing presses, were used formerly as rubber presses. These presses were purchased as scrap, overhauled and speeded up for use in shell drawing. Each press has a piston diameter of 16 in., stroke of 35 in. and at 1250 lb. per sq. in. has a capacity of 125 tons.

The pierced blank is placed in a bottoming pot which forms the boattail on the forging and sets the thickness of the base. The forging is then grasped by tongs and pushed on the draw mandrel. While the ram returns, the bottoming pot and stops are removed. The press is then reversed and the forging is forced down through two draw rings. This operation reduces the forging in diameter and elongates it to size.

The forging is stripped from the draw mandrel by spring-operated strippers below the draw rings and drops out a chute in the bottom of the press, from where it is grasped with a pair of hand tongs by a helper. The heat and turn number are stamped on the forging, after which it is placed, cavity down, over a wicket on a monorail conveyor. To normalize it while cooling and thus aid in machinability, a muff is placed over the forging. The forging travels on this conveyor for 2 hr. before it is removed at the rough turning lathes.

The forgings are checked and inspected while hot. The company keeps eccentricity to a minimum by correcting it in the piercing operation, where it first appears. If eccentricity is corrected here, it will not occur in the draw-press operations.

During the writer's visit to this plant, production records were observed showing a scrap loss in forging of only 0.7 per cent over a period of three months. This is more proof that good shell forgings can be made on revamped equipment. More than anything else, however, it is that Yankee ingenuity and determination that the men of this plant possess that pieced together these various pieces of scrap machinery and made records of productions which won the Army-Navy "E" award and which will finally win victory for the Allied Nations.

The author gratefully acknowledges thanks to Wm. J. Grace, works manager and to Wm. A. Rosser, plant engineer, L. A. Young Spring & Wire Corp., Trenton, for their invaluable assistance and cooperation in the preparation of this article.

DESCALING slugs prior to piercing. Two of the converted hydraulic rubber presses may be seen in the background. Note the clear atmosphere due to the exhaust hoods at each press.

Broken Drills Removed With Dynamite

o o o

DYNAMITER ignites fuse after tamping dynamite into oil hole and inserting cap. Less than a thimbleful of explosive is used. Drill has broken off well down in hole.

o o o

A SALVAGE procedure for quickly removing broken drills from the oil holes of hundreds of precision made crankshafts is saving annually many thousands of dollars for the Ohio Crankshaft Co. The method, which employs dynamite, can also be used to remove broken reamers or plug gages. It is especially suited for clearing deep drilled holes.

Needed are only a clearing in which the salvage work can be carried out, common dynamite, fuse, caps, wire probe, putty and a brace and bit. The monthly breakage of drills at Tocco varies and the value of the crankshafts saved does likewise. Savings are computed on the style of crankshaft more than on the quantity from which drills have been removed. Recently, 93 shafts were blown free in one month. Their value was more than $42,000. In another month some 133 shafts valued at only $29,000 were treated. In comparison to the value of total production the number of crankshafts salvaged is not large but the savings resulting from this homespun procedure are.

The dynamiting technique is simplicity itself. The shaft in question is removed to a clearing outside the plant and placed on a platform, steel skid or the ground. With a wire rod, the hole is probed to determine position of the drill below the bearing surface.

Dynamite is taken from a standard stick of blasting powder and pushed from a small trough into the hole by means of a round stick. No more than a thimbleful is ever used. Generally, the amount is considerably less depending upon the size of the hole and the set of the drill. Practice has shown the proper quantity of powder to use for certain conditions and it is always best to put in less powder than too much.

A 6-in. fuse is next inserted into a small diameter, shoulder-free cap and dropped into the oil hole atop the charge. When ignited a heavy plank or metal shield should be placed over the bearing surface to check the flight of the drill member as it is blown free. Frequently, timbers are split or the drill penetrates metal guard sheets. It is wise to keep at a safe distance during dynamiting.

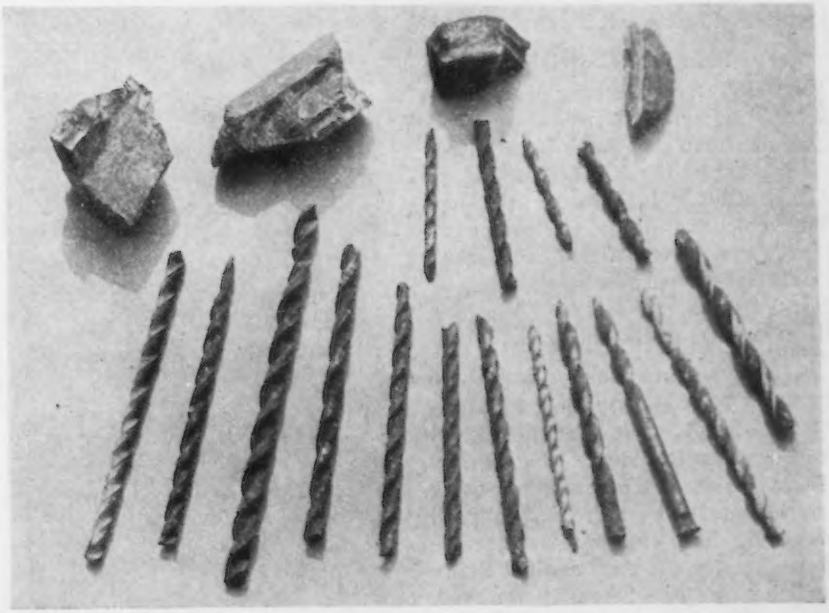
Drills are freed by the pressure of the blast which follows the drill flutes to the bottom of the hole and there reverses itself to drive the piece back out. As it leaves the shaft, the drill makes a ringing noise of metal striking metal.

Wonder has been expressed relative to the effect of the explosion upon the metal. There is no evidence of harm for thousands of crankshafts subjected to this operation have turned in long service records.

Drills removed vary in size from small 3/16 in. bits up to 1¼ in. core drills used in making lightening holes in camshafts. These big drills must be removed piece by piece requiring more than one shot. The dynamite is tamped into the oil hole of the drill itself.

Occasionally a drill breaks off flush with the bearing surface. To blow this necessitates building a putty dam of 1½ in. height above the hole. Into the dam is inserted a fuse and dynamite cap which on detonating either blows out the drill or enough of it so that the next charge can be inserted directly into the oil hole thus finishing the job.

COLLECTION of broken drills picked up from the ground around the blasting area. The large lumps are sections of a big core drill blown out by means of several shots. Note oil holes in core drill.



New Equipment . . .

. . . . Plant Service

. . . Recent new developments in protective clothing and dermatitis preventatives are described and illustrated in the following pages, as well as various other items relating to plant service.

ORIGINALLY designed for use in lumber mills, the safety "Kick-Back" apron No. 11394 has been put on the market by the *Industrial Gloves Co.*, Danville, Ill., for protection when using automatic hammers, drills, etc. The apron features the used of a bowed piece of fiber underneath a heavy canvas. The back of the apron next to the operator's body is quilted for comfortable fit.

Protective Hat

THE *Davis Emergency Equipment Co.*, Halleck Street, Newark, 4 has perfected a hard hat, called Hedgard, to give three-way protection to its wearer. The top of the crown is reinforced for direct blows. The side is built to stand glancing blows and the brim is made flexible yet strong so that it will not crack when dropped. A patented molding and compounding process makes the hat shatterproof.

Non-rubber Headband

A RESILIENT non-rubber elastic-action headband, Holdtite, is being made by *Carter-Lockard Co.*, 225 West 11th Street, Los Angeles. As the headband has the stretch of elastic, it is efficient for workers who wear goggles or respirators. It is adjustable and once set, it cannot loosen.

Industrial Clothing

INDUSTRIAL clothing coated with rubber, synthetic rubber or other synthetic materials have been put on the market by the *B. F. Goodrich Co.*, Akron, Ohio. Included in the new line, which will bear the company's brand, are firemen's and policemen's coats, general purpose work coats, industrial coats and worker's leggings, work jackets, pants and hats.

Faceshield

THE Type H faceshield has been developed by the *Mine Safety Appliances Co.*, Braddock, Thomas and Meade Streets, Pittsburgh, for quick attachment to the type K Skullgard protective hat. It provides durable protection for the face against flying particles and can be easily removed.

Clear, transparent plastic visors, 14 in. wide x 6 in. long, are employed. The fiber visor retaining strap is mounted on a pivotal joint, allowing upward or downward movement of the shield.

Sweat Bands

TO provide workers with greater comfort for hot weather work or where plant heat conditions cause discomfort, the *Aldine Paper Co.*, 373 4th Avenue, New York, has developed the Aldex sweat band. The outside covering assures silky-cool, non-irritating forehead contact. The cellulose fiber filler within the band absorbs perspiration on contact. The bands fit any size head, are so constructed that shape is maintained even when completely saturated and they are rugged enough for rinsing, drying and re-use.

Plastic Work Apron

A LIGHT weight plastic work apron for protecting war workers against dermatitis and other industrial hazards has been developed by the *Otto Aviation Corp.*, Bloomfield, N. J. Resistite is a compound of polyvinyl butyral resin impregnated into a fabric base. It will shed water, oil, gasoline, mild acids and alkalis, as well as iodine and similar compounds.

Eyemask and Hairguard

THE Standard Safety Equipment Co., 232 West Ontario Street, Chicago, has made extra ventilation available in a one-piece, all-plastic Sta-Safe eyemask by perforations above and below the vision area. The eye-protector has unusual impact resistance, is light weight and non-inflammable. It is available in clear or green antiglare model and in large or small sizes. The company also has designed the No. 18 Hairgard, which resembles the French Foreign Legion

head gear and covers all the hair. It is available in ivory or blue, with red, blue, green or white trim around visor. It is cleanable, adjustable, lightweight and cool.

Burn Treatment

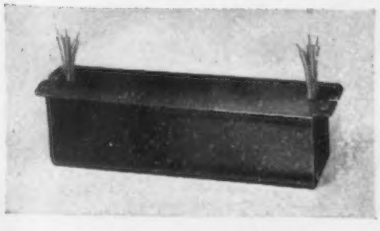
AS a means of reducing manhour loss from industrial burns, the *Gebauer Chemical Co.*, 9410 St. Catherine Street, Cleveland, is marketing a stable, tannic acid solution under the name of "Tannic Spray." The solution may be sprayed directly from the bottle over the affected burn area, materially reducing the probability of blister formation, infection and other complications.

Safety Glove

DUE to shortages of asbestos cloth used in the manufacture of asbestos gloves and mittens for industrial purposes, the jumbo size all-leather wool-lined one-fingered mitt has been designed by *Industrial Gloves Co.*, Danville, Ill. Made of heat resistant leathers, the mitt pattern assures adequate ventilation and coolness to the operator. The 4-in. gauntlet on the Steel Grip Safeguard No. 14730 gives extra protection at wrist; thumb is reinforced with leather strap.

Fluorescent Lamp Ballast

An air-cooled type of fluorescent lamp ballasts for exposed mounting on fluorescent lamp fixtures is being marketed by the *Acme Electric & Mfg. Co.*, Cuba, N. Y. The leads are brought out through outlets in the base plate. It is claimed that because of the exposed installation, the ballasts will operate at lower ambient temperatures than enclosed type ballasts.



Waterproof Creme

FOR plumbers, tinsmiths, heating men and others subject to contact with acids, alkalis and other materials, the *Cadet Creme Co.*, 151 Farrar Avenue, Worcester, Mass., has placed on the market "Skin-Kote," a waterproof creme which is said to be unaffected by carbon tetrachloride, toxic petroleum solvents, ether, thinners and other solvents which defat tissue, causing dryness, cracking and infections.

Breast Protectors

THE Saf-t-Bra designed by *Willson Products, Inc.*, Reading, Pa., is shaped to comfortably adapt itself to the contours of the female figure. Available in three sizes, small, medium and large, it is made of a durable plastic, which can be cleaned

easily and is attractively colored in fleshtone. It not only provides protection for the breasts, but is designed to extend well back under the arms to prevent possible painful injury of the delicate and sensitive lymphatic glands.

Skin Protector

A SKIN protector has been announced by the *Commercial Solvents Corp.*, 17 East 42nd Street, New York, which is called the CSC Protector. It is non-sticky, white and greaseless, and it is claimed it will not irritate sensitive skin and has no drying effect. It is said to be protective for four to five hours after application.

Hand Creme

DESCRIBED as the "visible glove," Neo-film, the protective coating brought out by *Jones Medical Laboratories, Inc.*, 800 Huron Road, Cleveland, is a liquid which guards the skin from cutting oils, greases, coolants, lards, oxide fumes, red lead, etc. It washes off easily with soap and water, carrying off all harmful residues.

Goggle Cleaning Station

TO encourage workers to wear their goggles and to keep them clean, the *Mine Safety Appliances Co.*, Braddock, Thomas and Mead Streets, Pittsburgh, has designed a goggle cleaning station for wall mounting throughout the plant. The compact case is equipped with Fogpruf, a lens cleaning and anti-fogging agent, and optical wiping tissues. A tap on the inverted vial sprays Fogpruf on the goggle lens. Cleaning tissues are pulled from the opening in the top of the station and discarded into a receptacle in the lower part of the case.

Protective Cream

THE Tarbonis Co., 1220 Huron Road, Cleveland, has developed a cream as a specific for various skin disorders. It is recommended where there is occupational dermatosis whether due to chemical irritation, chronic exposure to abrasives, work with cutting oils, reagents, acids, etc. The cream is greaseless, clinically non-allergic and non-irritating.

Fluorescent Lighting Fixture

DESIGNATED the Aristolite, a commercial fluorescent lighting fixture, in sizes for 2-40, 3-40 and 4-40 watt lamps has been announced by *Edwin F. Guth Co.*, 2615 Washington Avenue, St. Louis 3. A steel housing totally encloses all accessories and wiring. End-design permits flush-abutment of units when continuous installations are desired. The fixture can be suspended or can be mounted close to the ceiling. According to the manufacturer, the special lens design glass utilized breaks up the rays to

satisfactory brightness levels yet has high transmission qualities. The glass panels are easily removed for servicing and relamping. A Masonite reflector directs 85 per cent of the light downward.

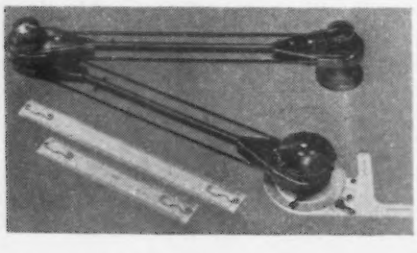
Injection Molded Nameplates

INJECTION-MOLDED nameplates of Tenite, used to mark steam and diesel engines, will not corrode and the outlines will remain distinct, according to *Tennessee Eastman Corp.*, Kingsport, Tenn. The nameplates, with one color an inherent

part of the plastic and another furnished by paint, contrast sharply with the metal of the engines. The plates are fastened to the engines by means of machine screws, and serial numbers and other data are stamped on with metal stamping dies.

Portable Drafting Machine

A SMALL drafting machine that can be mounted on a portable board and used in shop or field is being produced by the *V & E Mfg. Co.*, Pasadena, Cal. It is called the Vemco Jr. drafter and is made of shock-resisting plastics. It features accurate, parallel motion over the entire board, a full circle baseline setting, pre-lubricated and double-sealed bearings and enclosed pulleys. Disk brakes at anchor and elbow allow it to be used on steeply inclined boards. Aluminum



scales 8 and 10 in. long fit into slotted chucks in the positive scale holder. The protractor is graduated in degrees with figures by quadrants. A 10-in. vernier plate can be supplied.

Aircraft Hose Clamps

AIRCRAFT STANDARDS PARTS CO., 1711 Nineteenth Avenue, Rockford, Ill., has added model M-6 for ¼, ⅜ and ½-in. hose and model No. M-10 for ⅝ and ¾-in. hose to its line of aircraft hose clamps. By using the extra take-up in the band, the M-10 can be used on hose from ¼ to ¾ in. The band is spring steel strip perforated to correspond with the teeth of a worm gear and is drawn through the hosing by a worm thumb-screw. Lock wire is not required.

Oil Reconditioner

A COMPACT, portable oil treating unit has been developed by the *Sparkler Mfg. Co.*, 313 Lake Street, Mundelein, Ill., for reconditioning cutting, grinding and honing oils that should be heated before filtering. The unit consists of a 100-gal. mixing and heating tank that is equipped with electric immersion heaters, a mechanical agitator, a thermometer, a filter aid storage box of 50-lb. capacity, a main line fused knife switch, a magnetic push button controller, a Sparkler model 18-D-12 horizontal plate 600-gal. per hr. filter, a rotary pressure pump and a 1-hp. motor. The pump is so arranged that it can be used to transfer the oil from the pump into the heating and mixing tank and also to pump the oil through the filter. Tank will heat 100 gal. of oil from 80 to 180 deg. F. in 30 min.

Krimp-Sealer

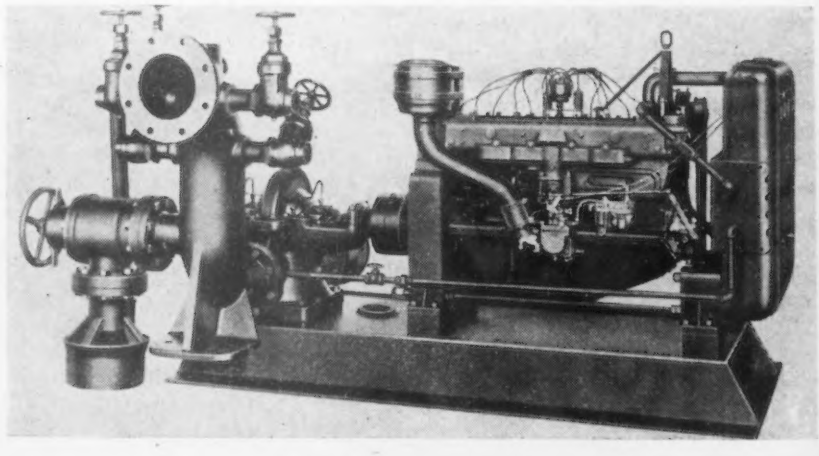
PACK-RITE MACHINES, 828 N. Broadway, Milwaukee, announces an improvement in the design of their E-Z sealer, used to krimp-seal heat-sealing bags for arsenals, aviation plants, metal parts manufacturers, etc. Designed for foot pedal operation, the krimper bars are mounted on insulater blocks to confine the heat. Special heating elements are used in order to take care of all types of heat sealing materials.

Mansaver Grab

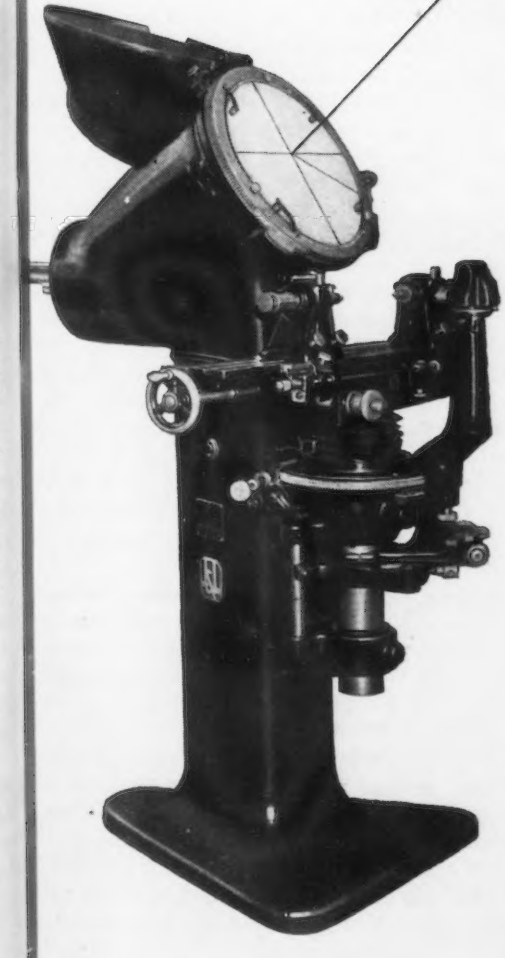
J. B. ENGINEERING SALES CO., 1732 Orange Street, New Haven, Conn., has developed a Mansaver grab which is capable of lifting 100,000 lb. at one time. It picks the load up by means of pans and can be adjusted to grab pans of varying widths. The equipment also can carry loads 20 ft. long, 7 ft. high and varying in width from 100 to 110 in. It is operated by one man from the floor by means of a chainwheel. It is offered also with a motor drive where frequent operation is desired.

Fire Pumps

FOR times when electric power or steam pressure is not available, *Fairbanks, Morse & Co.*, 600 South Michigan Avenue, Chicago 5, have developed a line of gasoline engine-driven fire pump units in capacities of 500, 750 and 1000 gal. per min. Quick and reliable starting is featured. They may be equipped for automatic operation starting from pressure switches or thermostats.



Beyond a shadow of a DOUBT!



In inspection operations there is no way of gaging the consequences of doubt . . . but there's one sure way of gaging *beyond a shadow of a doubt!*

That method is with the use of **Jones & Lamson Optical Comparators,** projection machines for measuring and comparing objects by means of a magnified shadow.

They measure angles in degrees and minutes; lead or spacing; height or depth . . . They photograph the enlarged shadow, without the need of a dark-room . . . They compare objects with a master outline . . . They permit rapid inspection and measurement of the many forms that are difficult or even impossible to inspect by direct gaging.

Any man or woman with a few minutes of instruction can operate this machine with speed and precision—a matter of particular importance in these days of manpower shortage.

There's an experienced Jones & Lamson Inspection Engineer near you. Call, write or wire for this service to Jones & Lamson Machine Company, Springfield, Vermont.

For rapid, economical inspection . . . BEYOND A SHADOW OF A DOUBT!

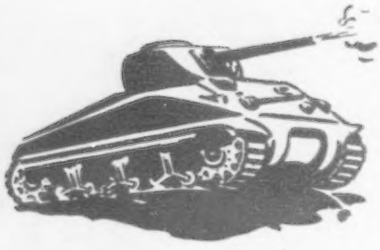
Assembly Line . . . .

STANLEY H. BRAMS

• Equal pay for equal work keynotes drive of Auto Union in brief filed in General Motors case . . . Chevrolet develops a more economical method of obtaining test coupons.



DETROIT—An attack on one of the broad philosophies motivating the War Labor Board was a feature of the negotiations of the United Automobile Workers Union with General Motors Corp. The union stand was that the board is collapsing because, among other reasons, it looks upon each labor problem as an individual case, rather than a segment of the broad labor panorama.

With this springboard, the union strongly urged its industry-wide platform of equal pay for equal work, an objective set forth at the Buffalo convention as primary, and one whose implementation commanded most of the attention of a recent meeting of the International board in Chicago.

In the GM negotiations, whose findings are now being studied by NWLB in Washington, the union declared that the company's tool and die work classifications are paid largely on an equality basis, with identical arrangements set up for GM plants through Michigan, Ohio, Illinois, New York, and New Jersey. The claim is made that if these skill classifications are to be compensated equally in these various plants, then similar provision should be made for production workmen.

Looking at today's broad auto industry picture, the union proposed to divide it into six general classifications insofar as wage scales are concerned. These are: Tank production and heavy armored mechanized units; engine production—aircraft, auto and diesel; wing and fuselage fabrication and assembly; guns, shells, and general ordnance; forges and foundries; and tool and die, pattern makers, maintenance and related skilled trades.

Obviously these breakdowns are for the war period, but they are readily translateable into peace-time equivalents. The tank production classifications proposed by the union, as follows, are roughly similar to jobs in an automobile or truck assembly plant: Welders, assembly hands, grinders, drill press operators, lathe operators, milling machine operators, flame cutters, spray painters, and tank testers.

Similarly the aircraft engine job classifications set forth by the union could apply in almost any type of motor production plant: Drill press operators, milling machine operators, lathe operators, rough and precision grinders, assembly hands, men inspectors, shapers, surface finish polishers, Bullard operators, filers and burrers, boring mill operators, sintering, gear cutting machine operators, and balancing on cranks. All these classifications, of course, would be further broken down in detail.

WAGE differentials have quite definitely been causes of disagreements in plants of the auto industry in the past. This writer recently heard a long complaint from a level-headed acquaintance working at a machine in one of the largest Detroit plants. This man is paid $1.15 per hour for his work, producing tank parts. In the same plant, he said, a few aisles away from his machine are other men working on identical machines to approximately the same tolerances, producing aircraft engine parts. The men working on these aircraft parts, however, are paid $1.35 per hour. Quite obviously here is a made-to-order cause for labor relations friction.

The examples in the union brief on the General Motors case cited smaller differentials in armor plate welding pay in various eastern Michigan plants. Fisher Body plants at five eastern Michigan points pay $1.29 an hour for this work, the brief stated, while Chevrolet-Flint has brackets of $1.24, $1.29 and $1.34; Ford, Detroit, pays $1.25; and Chrysler, Detroit, pays $1.25, it declared.

A variety of factors are at hand here beyond the simple issue of equal pay for equal work. However admirable may be the equality ideal from the workingman's standpoint, it should be applied within regional limitations (certainly the paying of Detroit level wages in an automotive plant in a southern agricultural district, for instance, would badly upset the equilibrium of that latter area).

Then, too, any installation of equal pay scales for equal work would be obviously intended by labor groups to be tacked onto the highest going wages for the particular job, rather than the median or the average. Questions of efficient operations therefore become inevitably tied to the problem implying that one company would survive at a uniform rate, while a second might perish.

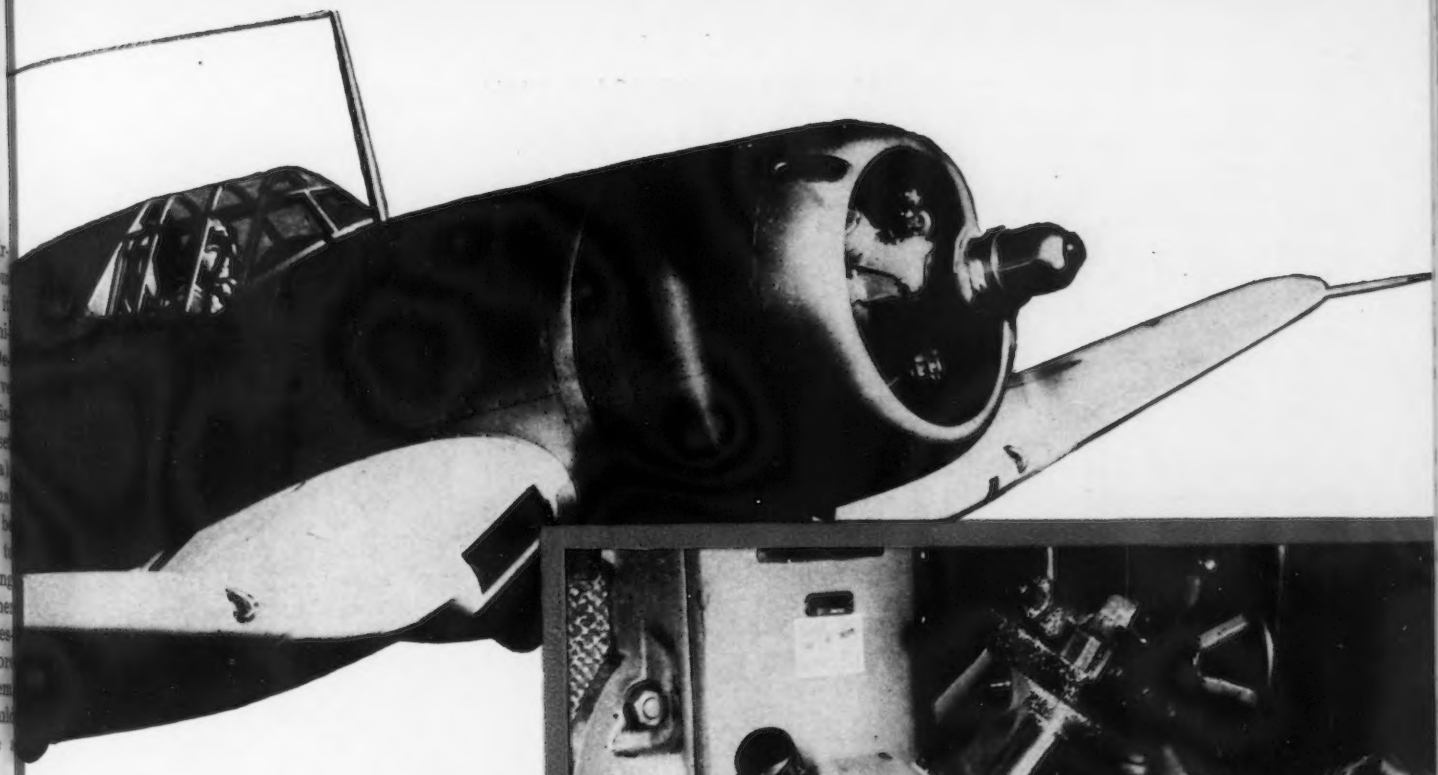
Too, there is a faint suspicion of internal union politics attached to this entire program. A centralized wage schedule would make future negotiating for pay raises much simpler. Concurrently, it would increase the power of the central administrative board, eliminating much of the functioning of the locals of the unions. This may not necessarily be part of the union thinking. Then, again, it may.

Finally, a fine question of free enterprise is involved. Standardization of wages could logically be followed by standardization of selling prices, standardization of profits, and standardization of everything else. The European name of this is *fascism*. The difference is that in Europe these "reforms" were sought by the "upper classes" to bulwark their positions. Here, now, they are sought by labor groups seeking to improve their positions. Someone must be wrong.

STREAMLINING of the procedure for testing heat treatment of forgings used in production of Pratt & Whitney aircraft engine parts made by Chevrolet has resulted in notable savings of steel.

Standard practice in the past has been to utilize test coupons forged as a part of each propeller shaft. A coupon was cut off an end of each shaft following rough machining and drilling of the center lengthwise hole, and was then wired to the parent shaft. Each coupon and its shaft remained tied together through the furnace quench and draw. The coupon was then detached, slit and turned to a regular tensile test bar.

Seeking to reduce the 16.84 lb. of



Basis For Confidence

American flyers aloft are trusting their lives to the precision workmanship of those who build their planes back home. And to the capacity of those builders to support this skill with the prodigious ***number*** of planes they need. Two axioms of war which underscore the fact that ***More Bullard Vertical Turret Lathes are in use by America's builders of airplane engines than in any other industry.***

• Bullard Vertical Turret Lathes

THE BULLARD COMPANY

BRIDGEPORT 2, CONNECTICUT

steel required for each coupon, Chevrolet engineers hit on the idea of utilizing stock which would not be subject to machining operations and which could be considerably smaller at the start than the original coupon. Tests were run, and the following procedure was decided upon:

As heats of steel come to the forge plant, estimate is made of the number of forgings that can be produced from them. Enough bar stock is withdrawn from the heat to provide a test coupon for each propeller shaft forging. This stock is furnished along with the forgings, to the manufacturing plant, which uses a band saw to slit the bar stock into pieces 1 in. square by 4¼ in. minimum length. This provides about 10 test coupons out of the same amount of steel previously required for one coupon.

One of the new type coupons then goes through heat treatment along with each individual forging, and subsequently undergoes customary tensile, yield, elongation, area reduction, and hardness tests. Of course the test coupon in the new procedure is not from the same forging with which it goes through heat treatment, but testing has established that as long as it is from the identical heat of steel, the differences in findings between it and the old-type coupon are negligible.

Steel savings for each propeller shaft, utilizing this system, run about 15.16 lb. Plans call for utilizing this program for crankshafts as well, with attendant saving of 19.26 lb. per unit.

Carrying out this conservation program, Chevrolet engineers have been granted permission to test one sample for each 10 master rods, providing additional savings. Another phase of the drive to save steel has resulted in the reduction of the amount of steel required for machining on the cylinder sleeve by 10 lb. per cylinder.

Baruch May Clarify Termination Records

Washington

• • • **Bernard M. Baruch** may soon report what are minimum requirements contracting officers must meet in making a record of contract terminations.

Based on the fact that War Department recommendations were largely followed in devising a uniform termination clause, it is assumed that Mr. Baruch will incorporate the War Department's present practices on record maintenance when he makes recommendations on the demands of termination records.

The War Department now requires the following record in every negotiated contract termination settlement:

1—Manufacturer's settlement proposal supported by certificates signed by the manufacturer and his suppliers, including inventory.

2—Report of War Department accounting personnel.

3—Statement by the contracting officer setting forth the basis of the settlement, together with an explanation of unusual situations and special reports by property disposal officers.

In view of the known accounting demands of the General Accounting Office with respect to the adequacy of records for audit, it is expected that no objection will be raised by GAO should the Office of War Mobilization make the foregoing record requirements standard for all war agencies.

Electrolytic Line Coats Zinc Sheets

Pittsburgh

• • • **Using the same** electrolytic lines that have revolutionized production of tin plate, Weirton Steel Co., a division of the National Steel Corp., is now turning out electrolytic zinc coated sheets at the rate of 160 ft. a minute in its **new precision** unit at Weirton, W. Va.

While most of the zinc coated sheets produced at Weirton are processed into ends for fiber shell canisters and ammunition containers, some of the company's recent output will be used to make automobile head gaskets and spark plug gaskets.

A list of suggested items for which electrolytic zinc coated sheets and strip may be utilized, according to the company, includes hot air conductor pipe and elbows, oil cans, spools and reels, Venetian blinds, furniture, moulding, expanded metal lath, corner bead, fiber box reinforcements, lamps, flexible hose and shafting, builders hardware and box strapping.

Three lines of electrically operated equipment, each 400 ft. long, can be used interchangeably to produce either tin plate or zinc coated sheets, which are fabricated into a wide variety of articles for war or civilian use.

The lines are designed to coat sheets up to 38 in. wide, from 0.0080 in. to 0.0370 in. gage (39 to 21 zinc gage) and coated from 0.1 oz. to 0.2 oz. a square foot on both sides. The product is marketed in coils or cut lengths down to ⅜-in. narrow strip.

The electro-plating unit, where the zinc coating is applied to the moving steel strip, is a three-deck section consisting of 24 identical cells, formed like troughs. These cells are 5½ ft. long, 4 ft. wide, and 8 in. deep.

For zinc coating, the cells are filled with a zinc electrolyte made from zinc chloride, sodium chloride, and aluminum chloride. The solution is mainained at a pH of 3.0, with temperatures ranging from 115 degrees F. to 125 degrees F.

On the floor of each cell there are 16 pure zinc anodes, and the total weight of the anodes in all 24 cells exceeds 33,000 lb. Current enters the cells through bus bars connected to the anodes. The current carries zinc from the anodes and deposits it on the moving strip steel, which enters and leaves each cell on rollers.

The low voltage generators deliver 60,000 amperes of power to the plating unit at all times. At a line speed of 160 ft. a minute, a current density of 200 amperes per square foot is required.

Washington . . . L. W. MOFFETT

• Military is force hindering reconversion . . . Public weary of complacency charges . . . Government softness on strikes and overstaffed agencies shows apathy and political expediency.

THE policy of the government to bar "general resumption of civilian production at the present time" as expressed by WPB chairman Donald M. Nelson, is partially based on a psychological factor. The policy represents military thinking. Whether it is right or wrong may be debatable, but the Army and the Navy believe that there is too much civilian complacency over the war situation. To permit anything like broad scale reconversion, it is feared, would increase this so-called complacency and give rise to a business-as-usual trend in the face of the fact that the country now faces the most serious crisis in history.

Definitely, some government agencies do not share this thinking of the military branches of the government, but have had to yield to it. That they have had to yield is understandable. The military services only have to point to the growing battle casualties, to the fact that the European invasion yet to come is expected to be costly in lives, and that any let-down on the home front might well add to the sacrifice of lives that lies ahead.

Nevertheless, government agencies not in agreement with military viewpoint cannot understand why civilian production cannot be started when manpower, materials, and capacity are available. They do not accept the idea that this reflects complacency in any sense. On the contrary, they consider that it shows an acute awareness to the need of maintaining production and employment and therefore the economic structure so far as is possible under war conditions without in any way interfering with military demand.

It is contended that a policy of unjustified restriction on civilian output will cause a tendency toward overproduction of war weapons. Some of them might well become obsolescent before needed and therefore cause a waste of materials, manpower, and capacity. This policy carried too far, it is maintained, would mean a rough rather than a smooth transition period. This view is based on the premise that the longer industry is kept from making firm plans for reconversion, the greater the economic repercussions from unemployment will be.

UNCERTAINTIES of war clearly must be kept uppermost in mind and every preparation made to guard against reverses. Nor, it is contended, should the civilian population be falsely encouraged in the thought that the war is nearing its end, either in Europe or in the Pacific. To allow the home front to go any "softer," it is maintained, would inevitably affect the morale of the front line troops. The pressure for a National Service Act is said to be prompted to a considerable extent by this kind of thinking by the armed services.

The armed services probably go to extremes in their concern over so-called civilian complacency, but, if they have to lean over one way or the other, the backward tilt is the slant they should take professionally. At least it is the safer side. At the same time, there is undoubtedly a growing resentment in the country over excessive admonitions against complacency that come from the military and other government sources. The tone of these warnings might indeed be altered. They would be more effective if they were less pontifical. The public has grown weary of being treated as if it was a kindergarten class and as if it didn't know that war is what Gen. William Tecumseh Sherman said it is.

Certainly most of the public must be acutely aware of the implications of war. With some 10,000,000 fathers, sons, and brothers in the military services, directly affecting about one-third of the families of the country, it simply is not true that there is widespread complacency. There still is undoubtedly too much complacency — any apathy is too much — but to assume that it is so widespread as appears to be assumed by some statements emanating from government sources is overdoing the job. The growing casualty lists and realization that they will become much greater has given the civilian population for the most part an intimate understanding of war and unquestionably has caused a lessening of complacency.

FOR that which remains it would be well for the government to analyze itself and see if it isn't responsible for a great deal of it. Its soft attitude toward strikes, its vastly overstaffed bureaucracy of almost 3,000,000 civilian employees, which could be reduced by 50 per cent at least and place the government on a better war-footing, surely reflects an apathy on the part of the government that smacks of political expediency. Thus the tax-paying public whose so-called lack of war consciousness might well turn the tables and warn the Administration against its own weaknesses.

But notwithstanding differences of view regarding complacency or other factors, the big thing is to get along with the war and to bring it to a successful conclusion as soon as possible. To this end any reconversion to civilian production, with sound reason, will be delayed until after the invasion on the western front. Arguments that there now is idle capacity in the steel and other vital industries, and that components and labor are available for much greater civilian production will not prevail. For the present the stepping up of such output will continue to be only on relatively small scale.

ONCE the European war has been ended, however, it may be expected that there will be an early shift to much larger peace production. As anxious as management is to return to greater civilian production after the war situation justifies that conversion, labor, already urging increased peacetime output, will become much more insistent because quite properly it will not stand by idly and see a needless growth of unemployment.

There are varying estimates of the effect on war production after Germany is knocked out. One estimate, which many think is considerably too high, is that with the defeat of Germany war production can be cut 80 per cent. The remaining 20 per cent,

Below: An internal job. Here the Internal Grinding Attachment has been pulled down into position for grinding the bore in a short shaft to an accurate plug-gage fit. The attachment is standard equipment always in place and may be set up at a moment's notice.

Above: An External job. Grinding the taper—3½" per foot—on the shank end of an attachment driving gear. Notice the Internal Grinding Attachment on the front of the wheelhead. The attachment is up and out of the way but ready for instant use.

CINCINNATI 12" Hydraulic Universal Grinding Machine

Give Your New Product A BREAK in the Toolroom

The first few samples of your new product for tomorrow's market must be made on machine tools, in the *tool room*. There, they pass through their most critical period. There, the product can be started on its way to success or failure. With versatile and up-to-date tool room machines for manufacturing the parts, the chances are that the performance of the assembled unit will equal blue-print specifications.

CINCINNATI Hydraulic Universal Grinding Machines have all the qualifications for tool-room work of this type. They will size accurately, within .0001", and produce exceptionally smooth finishes with no extra effort. Changes from external to internal or face grinding may be accomplished in a few minutes. The table continually reverses within .004", enabling the operator to confidently grind close to shoulders.

These few statements give you an idea of the fine work which can be produced on CINCINNATI Hydraulic Universals. Complete information may be obtained by writing for catalog G-486-1 (12" size) or G-474-1 (14", 16" and 18" sizes).

CINCINNATI

CENTERTYPE GRINDING MACHINES CENTERLESS GRINDING MACHINES
CENTERLESS LAPPING MACHINES

it is claimed, will be enough to knock out Japan. Perhaps a more general estimate is that a 50 per cent cut is all that can be made, leaving the remaining 50 per cent on war production to finish the job of crushing Japan. But whatever the percentage of the cutback, it will be so large that a lot of capacity will be freed for civilian production and it will be needed to supply the peace economy of the nation.

While relatively this country has not suffered from shortages, nevertheless, it has been on a short diet and has an appetite for consuming many classes of products for repairing machinery and all sorts of utensils and gadgets, to say nothing of what it will want in the way of automobiles and heavy durable goods items when full peacetime production is restored. Moreover reconversion on a gradual rather than a sudden and complete basis certainly will relieve the impact of the numerous and serious problems that will be involved when the war comes to an end.

Sympathy Shown for Postwar Cartels

Washington

• • • **American industrial** and some governmental support is appearing in favor of cartelization of all industries. Departments containing powerful groups which are said to favor this solution to postwar foreign trade problems, including unemployment, are the Foreign Economic Administration, WPB and the State Department. Some sympathy is showing in Congress.

As the Federal Trade Commission, the State Department and the Justice Department have assigned groups to study cartels, the Kilgore (Senate) Committee on War Mobilization released last Friday an anti-cartel monograph prepared by Corwin D. Edwards, chairman of the Policy Board, Anti-Trust Division, Department of Justice.

While Senator Kilgore declared that the report represents in no way the opinion of the Committee members, he said:

"The study points up the necessity for developing a foreign economic program that will both preserve the integrity of our domestic economy and enable us to maintain friendly economic and political relations abroad. Such a program along new lines is requisite if we are to establish an enduring peace after the war."

The Corwin report says that the British are chief exponents of cartelizing all American industry.

"In a recent discussion with the president of the United States Chamber of Commerce, Lord McGowan, chairman of the board of Imperial Chemical Industries, declared that he saw no hope for postwar cooperation between British and American business unless the American Sherman Act were repealed," Mr. Corwin said.

According to the report, the most ambitious of the publicly announced programs is that of the World Trade Alliance which is promoted from England by Sir Edgar Jones, a former director of Courtaulds, Ltd., and an executive of the international tin plate cartel.

In discussion of his proposal, Sir Edgar asserts that it requires two basic conditions:

"1. For every class of products the organization must be universal.

"2. Raw materials must be organized as well as manufactures."

He also points out that control of exports must necessarily be associated with similar control of internal markets in each participating country.

THE BULL OF THE WOODS — BY J. R. WILLIAMS

Creighton and Hazlett Are Advanced by J. & L.

Pittsburgh

• • • **William J. Creighton** has been made executive vice-president, Jones & Laughlin Steel Corp., Pittsburgh, by action of the board of directors on Feb. 7. Adam J. Hazlett was appointed general manager of sales.

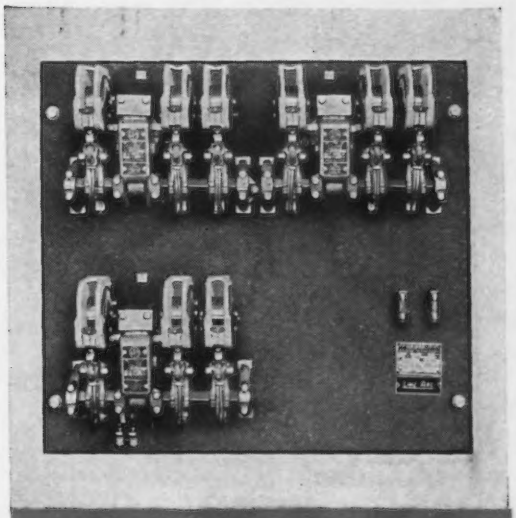
Mr. Creighton entered J. & L. as a clerk in 1900, became financial vice-president in 1928, when he was elected a director of the corporation and a member of its executive committee.

Mr. Hazlett, after graduation from college, was employed by the West Penn Steel Co., in the sales department. He later became sales manager, and subsequently president, of the Eastern Rolling Mill Co. In 1938 he came to J. & L. as manager of strip and sheet sales.

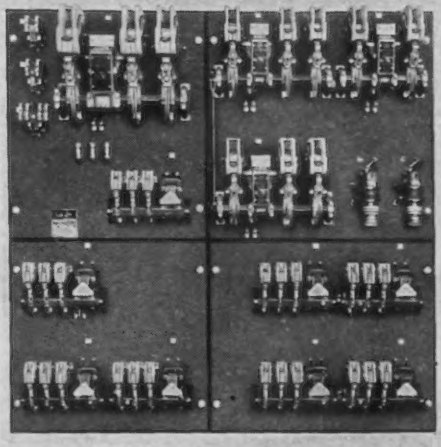
William J. Filbert Dies

• • • **William J. Filbert**, 78 years old, director of U. S. Steel Corp., a member and former chairman of the Corp.'s finance committee, died Feb. 4 at his home in New York after a brief illness. Mr. Filbert served as comptroller for 30 years. At the time of his death he was senior director of the company, having been a member of the board continuously for nearly 25 years.

Control by EC&M assures high efficiency of BILLETEER



EC&M *LINE-ARC* Contactor Control for the Billeteer tool head and elevator drive. This unit is mounted in the cabinet on the Billeteer.



EC&M Controller for separate mounting in cabinet which controls other motions of the Billeteer.

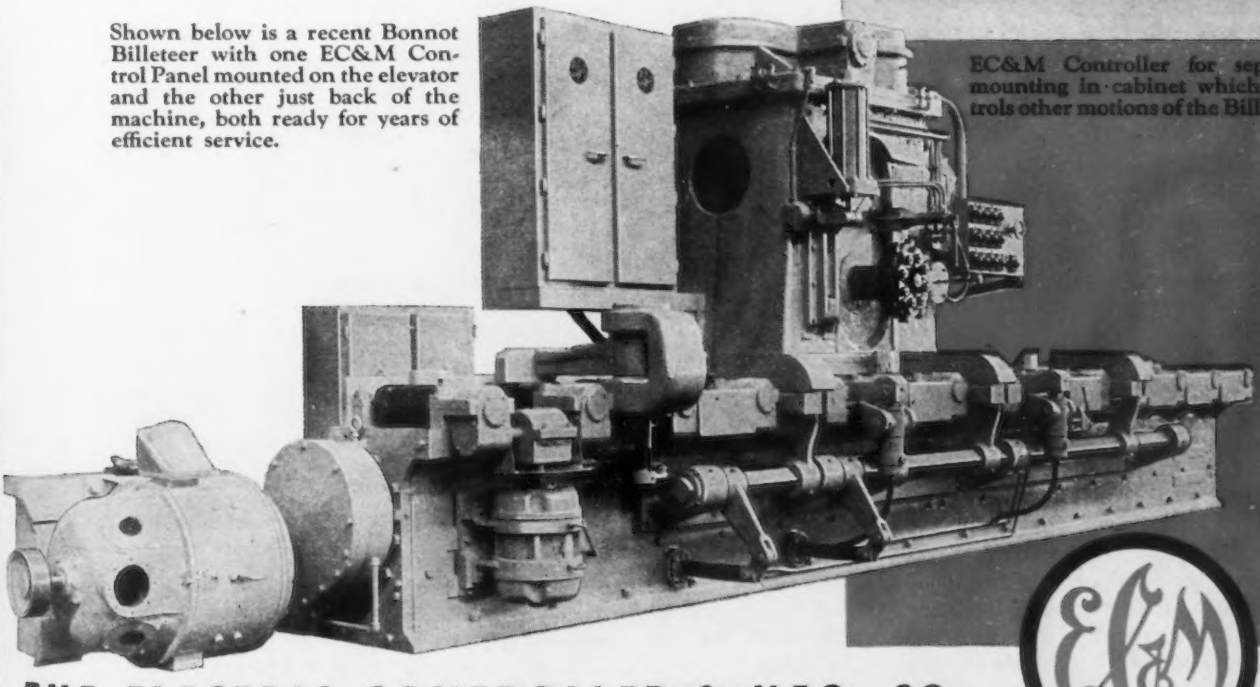
●Spotting the cutting head of the Billeteer over the seams and defects of billets is not only a continuous job but one which requires perfect dependable control of a machine that weighs 150,000 pounds.

The operator must have fingertip control of the cutting head in addition to operating the approach and runout tables and all manipulation of the billet itself.

The unit shown below was just completed for a steel company which has three other Billeteers EC&M equipped. They know the rugged, twenty-four hour a day punishment these controls must undergo.

Our nearest office will gladly supply complete details.

Shown below is a recent Bonnot Billeteer with one EC&M Control Panel mounted on the elevator and the other just back of the machine, both ready for years of efficient service.



THE ELECTRIC CONTROLLER & MFG. CO.

2700 East 79th Street **Cleveland 4, Ohio**

WEST COAST . . . OSGOOD MURDOCK

• "No Previous Experience Necessary" catchlines removed from shipyards' want-ads . . . Neither Maritime Commission nor Navy have yet listed or released any surplus material . . . 40% of 91% of Douglas workers would prefer no union.

SAN FRANCISCO—Bumpy, narrow gage, little cable cars still creep up and shinny down the steep hills of this sensitive city, much to the sentimental satisfaction of old inhabitants and the playful amusement of visitors. Each little carriage-painted conveyance must be operated by a strong-arm gripman on the front end and a tangle-footed conductor, now sometimes a slim conductorette, who can thread his or her way through the narrow aisle collecting fares, giving out tiny transfers, calling "Look out for the curve," and trying to get inside passengers off while retaining precarious hangers on the outside steps front and rear, right and left.

An old-time gripman with years of service has been missing the last year or so. The other day he appeared back at his old traditional post. "Where have you been?" asked habitual passengers as they recognized him back again.

"I've been over at the shipyards as a pipe-fitter's helper, making good money and earning some of it sitting down. But I've got a wife and two kids and I figured it was about time to settle down and get back to my regular job. This thing won't last forever."

Several thousand others, like Joe Gripman, have been doffing their gaudy painted tin helmets for the last time and going back to their old jobs and old haunts—sometimes way into the interior, some voluntarily, many by request. Some 3000 shipyard workers in this Bay area have been discharged recently, mostly for chronic absenteeism or incompetence, according to the Maritime Commission. As gray iron foundries, munition plants and facilities construction projects slack off, and as a pretty steady stream of good men are released from military service, some former civilian craftsmen and some trained by the Army or Navy, better men are fed in at the top and the poorest sift out the bottom. As the feverish pressure for speed is relaxed to steady routine production and as technical demands for repair work replace the mass manpower confusion of emergency cargo hull quantity production, shipbuilding on the West Coast in 1944 will be more of a trade and craft and less of a parade and circus. As in any conversion and evolution, growing pains again are suffered.

Contrary to thoughtless, popular impressions and despite temporary restlessness and misunderstanding by workers, the six-day week universally adopted for Pacific Coast shipyards since Jan. 1 was expected to and has actually speeded and made more efficient ship construction. Management discovered, and convinced the Maritime Commission, that staggered days off decreased morale because a crew never was complete. Sunday crews and personnel have always been minimum; as the months wore on and the novelty wore off, more and more workers preferred a Sunday holiday, especially women and housewives. It is further self-evident, after two to three years of operation, that more maintenance and overhaul is required, so that one day's rest for plant and facilities out of seven is increasingly useful to maintain mechanical and physical efficiency. It has been found particularly valuable to have all foremen and leadermen present every working day. The same number of total manhours are now distributed over six days that were formerly spread thinner and staggered over seven.

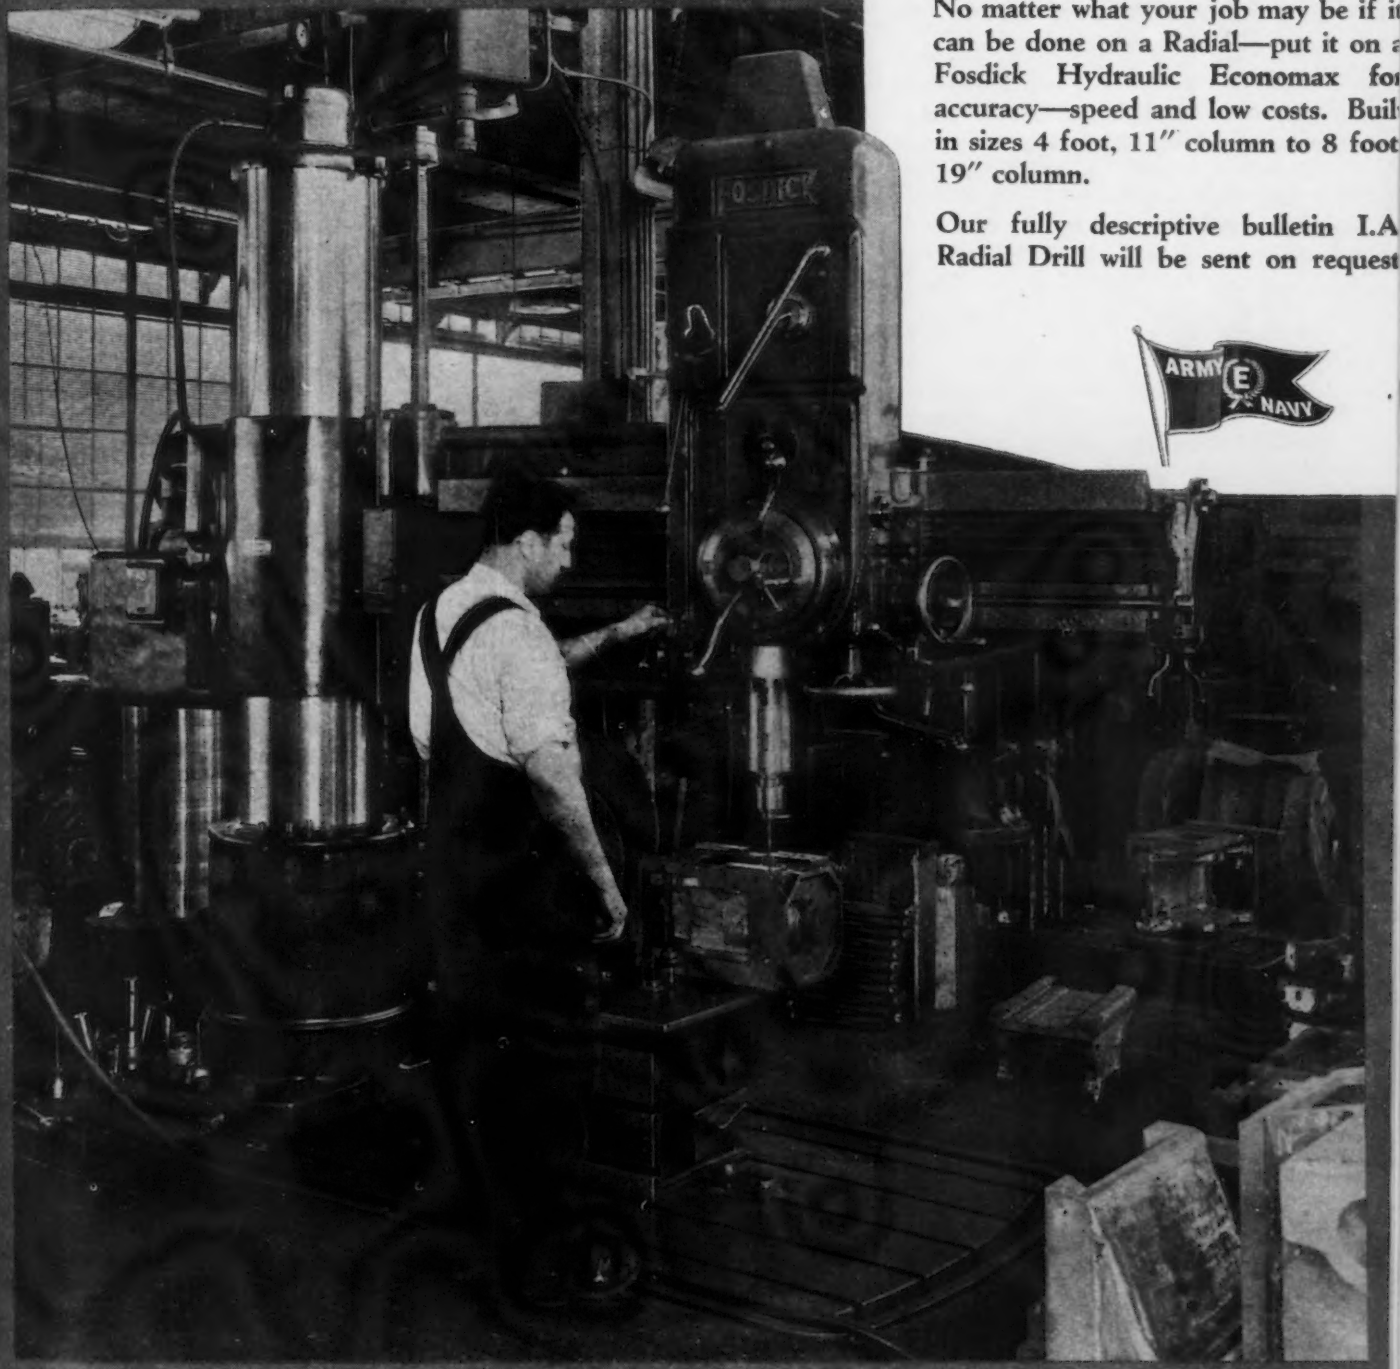
JOSHUA HENDY IRON WORKS at Sunnyvale, a principal manufacturer of propulsion machinery for Maritime vessels, is switching over to two shifts a day in most departments, because it is found that greater production results from two full shifts of skilled labor fully foremanned and superintended than from trying to keep wheels turning with a midnight-to-dawn skeleton crew. Kaiser's Richmond Shipyards are asking 12,000 of their 90,000 workers to shift to "other types of work," presumably more directly productive. Of the first 3000 interviewed, 1500 agreed to switch while the other 1500 quit. Machinists, electricians, sheet metal workers and pipe fitters are wanted, but checkers, laborers, helpers, clerks and assistants are not now needed in the old quantity. Although Liberty ships are still being made at Richmond, three or four of the Victories are in progress. At Portland, Oregon Shipbuilding Corp. has launched its 322nd ship in 32 months and the switch to Victories is just about complete. It's taking 100 days to complete the first one, instead of around 30 days for a Liberty, but they hope to get it down to 50 days when the switchover is complete. On Puget Sound, Seattle-Tacoma Shipbuilding Corp. has launched its 25th destroyer, completing the original $175,000,000 contract for 10 of 1750 tons and 15 of 2100 tons displacement. Additional contracts have been awarded for 21 more destroyers which will carry the yard through the middle of next year.

Marinship Corp. at Sausialito, Cal., said to be the Maritime Commission's "dream yard," is about to make its third major conversion, an estimable record. The last of the West Coast yards to be built and therefore getting the last crack at workers, it nevertheless had everyone's experience to go on. Under Bechtel management, it seems to have done the best job of worker training and morale building, and with a total labor force of under 20,000, there has been less turnover and apparently maximum production and performance. After constructing 12 Liberty ships on the six ways, the yard switched to tankers and has contracts for 64 which will require all of 1944 and part of 1945. The vessel now in production is 10,000 h.p., turbo-electric driven, and a long-run post-war craft.

The only present major Maritime repair yards on the West Coast are Moore's at Oakland on San Francisco Bay and Todd's Seattle-Tacoma affiliate on Puget Sound at Seattle. Repair work requires higher skill and greater

CAPACITY . . . SPEED . . .
and ACCURACY . . .

Fosdick Radials



● In hundreds of shops engaged exclusively in war production Fosdick Radials are speeding production — maintaining accuracy — and saving vital time.

These sturdy Radials have the stamina and power for drilling large holes accurately — the rigidity to maintain close tolerances on smaller diameter holes — a full selection of speeds and feeds quickly available in the head to assure the maximum of production.

No matter what your job may be if it can be done on a Radial—put it on a Fosdick Hydraulic Economax for accuracy—speed and low costs. Built in sizes 4 foot, 11″ column to 8 foot 19″ column.

Our fully descriptive bulletin I.A Radial Drill will be sent on request

ARMY E NAVY

FOSDICK MACHINE TOOL COMPANY
CINCINNATI · · · OHIO

resourcefulness by management and brings a considerably higher wage scale to the workers.

INVENTORIES of surplus material steel stocks listed by the WPB Redistribution Division for the 10th region, including California, Arizona, western Nevada and southern Idaho, approximate 22,000 tons. It is understood that for the Pacific Northwest states of Oregon and Washington, listed at the Seattle regional office, stocks so far listed approximate 15,000 tons. But no inventories nor lists are yet available from either the Maritime Commission or the Navy, by all odds the principal war steel buyers and owners. Traditionally the Navy is a hoarder of materials and may not get around to listing its surplus stocks for years, if ever. "We have no surplus now," declare Naval officers nominally in charge. Once liquidation begins in earnest, Maritime surpluses on the Pacific Coast are likely to make present Redistribution records seem puny, pilot figures. An orderly, businesslike beginning has been made in this disposal of surpluses, and WPB Redistribution officials as a clearing house agency are working closely with commercial distributors.

OF 21,000 workers at the Douglas Santa Monica plant, 91 per cent voted in the NLRB election Feb. 1, one of the highest percentages in a major labor election. Of those voting, 39.7 per cent were for no union, 34.3 per cent for the CIO United Automobile Workers of America and 26.1 per cent for the AFL International Association of Machinists. The electrical maintenance department held a separate election and 76.4 per cent voted for AFL Electrical Workers. A runoff will be held in a week or two between CIO and AFL.

At Seattle OPA has again taken to the courts with charges of interest to the steel trade. Western Steel Casting Co. Inc. is accused of sales above ceiling prices to the Navy during the past year. OPA attorneys claim that prices have been over double the ceiling. A judgment of $49,363 is asked, treble the $16,454 which it is claimed represents overcharges during the past year. It is understood that all Washington foundries have been checked and surveyed following what are stated to have been numerous claims for overcharge. Other suits are therefore expected.

"THE Fontana steel plant . . . is owned wholly by Kaiser Co. Inc. and its operations now and in peace time depend wholly upon the ability of each and every one of us to make it produce steel at prices which are competitive in the open market." Such is a statement Henry J. Kaiser addressed to his workers and associates at Fontana.

He goes on to say, "Our cost of production must be equal to or below that of our competitors if we are to continue to exist . . . We can expect within the very near future that keen competition for steel plate and other steel products will prevail on the Pacific Coast and that the price will decrease. . . . The plant is wholly owned by Kaiser Co. Inc., which company is in turn most heavily indebted to the Reconstruction Finance Corp. for funds. For this huge sum which we have borrowed we are paying interest at 4 per cent and have pledged collateral for its payment. Part of this collateral is in the nature of ship earning fees which the shipbuilding division of the Kaiser Co. Inc. is earning."

o o o

Steel Employment Lower During 1943

• • • **Employment** in the steel industry declined to 605,000 during December, the lowest since February, 1941, according to the American Iron and Steel Institute. The figure was 611,000 in November. Over the whole of 1943, the industry employed an average of 626,000 as against average employment of 647,000 in 1942.

Payrolls in December were $140,203,000, bringing the year's total to the record figure of $1,649,227,000. In 1942, steel payrolls totaled $1,467,059,000.

Wage-earning employees in the industry earned an average of 116.1 cents per hour in December as against 116.4 for November. Over the whole year 1943, wage earners averaged 113.5 cents per hour against an average of 105.6 cents per hour in 1942.

Wage earners worked an average of 43.2 hours per week in December, against 44.8 hours per week in November. Through 1943, the workweek averaged 43.0 hours as against 38.9 hours in 1942.

Steel Warehouse Chapter Founded in Colorado

Cleveland

• • • **The directors** of the American Steel Warehouse Association, Inc., have approved the establishment of a Colorado Chapter, W. S. Doxsey, president, stated. The territory of the new chapter includes the state of Colorado and parts of New Mexico and Wyoming. Members of the chapter are: C. A. Crosta, Inc., Denver, M. L. Foss, Inc., Denver, Goldberg Brothers, Denver, Hendrie & Bolthoff Mfg. & Supply Co., Denver, The Mine & Smelter Supply Co., Denver, and Silver Engineering Works, Inc., 3309 Blake St., Denver.

H. V. Waterman, Hendrie & Bolthoff Mfg. & Supply Co., is president of the new chapter; J. H. Singleton, C. A. Crosta, Inc., vice-president; and A. M. Hays, Hendrie & Bolthoff Mfg. & Supply Co., secretary-treasurer. Mr. Waterman is also Chapter Director.

. . . Cited for Awards . . .

• • • **The following** companies have received the Army-Navy E award for excellence in war production:

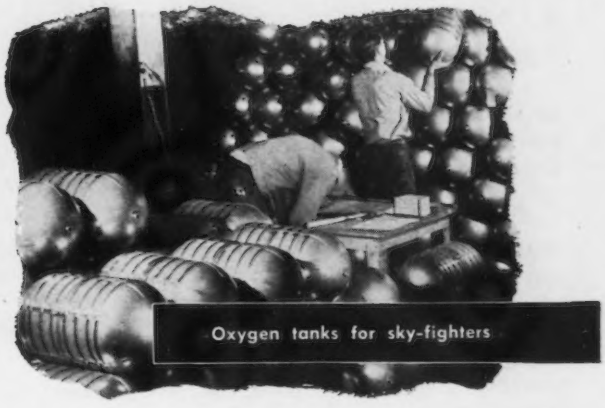
Balch Mfg. Co., Kalamazoo, Mich.
Butler Mfg. Co., Galesburg, Ill.
Carlton Lamp Corp., Newark, N. J.
E. I. du Pont de Nemours & Co., Inc., Electrochemicals Department, Wyandotte Plant, Wyandotte, Mich.
Freiberg Mahogany Co., Harahan, New Orleans.
International Pacific Pulp & Paper Co., Multnomah Lumber & Box Sales Co., Portland, Ore.
Manco Mfg. Co., Bradley, Ill.
Osborn Mfg. Co., Cleveland Plant, Cleveland.
Pittsburgh Piping & Equipment Co., Pittsburgh.
Roth Mfg. Co., Chicago.
E. J. Schoettle Paper Box Co., Precision Mfg. Co., Philadelphia.
Symington-Gould Corp., Gould Coupler Works, Depew, N. Y.
De Laval Steam Turbine Co., Trenton, N. J. (third star).
Babcock & Wilcox Co., Refractories Division, Augusta Works, Augusta, Ga. (second star).

Maritime M

Cooper-Bessemer Corp., Mount Vernon and Grove City, Pa., plants (second gold star).
Colonial Foundry Co., Louisville, Ohio.

YOU CAN GET MORE "STAINLESS" *Delivered Faster Now*

Pasteurizing tanks made of stainless



Oxygen tanks for sky-fighters

For a warplane's collector system

Stainless steel has been one of the "tightest" of all scarce metals. Now it is more readily available for W.P.B.-approved war and civilian uses, and delivery can be made faster.

Greater production of ARMCO Stainless Steels is made possible by more plentiful raw materials. Most of the alloying elements used in stainless—including chromium, nickel and molybdenum—are again fairly abundant.

For war uses it is not necessary to look for substitute materials. In fact, removal of restrictions is being considered for applications where it has been difficult to convert to other materials.

Resists Heat and Corrosion

ARMCO Stainless has many advantages, in war as well as in peace. Its hard, smooth surface withstands wear and tear; its high strength/weight ratio helps you design with lighter sections. Stainless defies heat and staunchly resists many forms of corrosion. It forms easily and can be readily welded.

If you make war equipment you'll find an ARMCO Stainless grade for every requirement. Just write to The American Rolling Mill Company, 821 Curtis Street, Middletown, Ohio.

STAINLESS ARMCO STEEL

The American Rolling Mill Company

PERSONALS

• **H. W. Catt** has been appointed manager of the chemicals and pigments department of the purchasing division of the B. F. Goodrich Co., Akron, Ohio. Mr. Catt joined B. F. Goodrich in 1929 and was engaged for 10 years in chemical research and rubber compounding. He succeeds **Dr. Victor E. Wellman**, who becomes director of purchases in the chemical division of the company.

• **Ralph J. Teetor**, president, Cadillac Malleable Iron Co., Cadillac, Mich., was nominated to succeed **L. C. Wilson**, general manager, Reading steel casting division, American Chain & Cable Co., Reading, Pa., as president of the American Foundrymen's Assn.

• **John C. Dilworth** has been named manager of sales for the railroad materials and commercial forgings division for both the Pittsburgh and Chicago districts of Carnegie-Illinois Steel Corp., and assisting him as district managers of sales will be **Orrin H. Baker** for Pittsburgh and **John J. Davis, Jr.**, for Chicago.

• **Walter L. Rice**, vice-president of Reynolds Metals Co., has been elected president of Reynolds Mining Co. He succeeds **R. S. Reynolds, Sr.**, founder of the company, who now becomes chairman of the board.

• **Martin J. Berlyn** has resigned as manager and chief engineer of the diesel engine division, Dominion Engineering Works, Ltd., Montreal, to become vice-president of the American Bosch Corp., Springfield, Mass., in charge of engineering.

JOHN O. CHESLEY, railway sales manager, Aluminum Co. of America.

• **Maj. Francis W. Hay**, formerly with Aluminum Co. of America at Bridgeport and Massena, has been named assistant resident representative of the Army Air Forces Materiel Command at the Buffalo plants of Curtiss-Wright Corp.

• **Gwilym A. Price**, vice-president of Westinghouse Electric & Mfg. Co., has been elected a member of the board of directors of the Pittsburgh Steel Co., Pittsburgh. **J. Herbert Carson** was elected comptroller of the company, and **J. N. White** was elected assistant comptroller.

• **William S. Wheeler** has been elected president of the Pennsylvania Engineering Works, New Castle, Pa., following the retirement of **W. H. Lewis**, who remains with the organization as chairman of the board of directors. Mr. Wheeler joined the company in 1905 as a draftsman and has served in all departments of the company. Previously he was vice-president and general manager. Also **Clark Rossiter** has been made vice-president and general manager, **P. M. Pattison**, vice-president and secretary, **A. L. Davis**, treasurer, and **H. L. McFeaters**, chief engineer.

• **R. W. Sutton** has been appointed purchasing agent of Truscon Steel Co., Youngstown, subsidiary of Republic Steel Corp. Associated for many years with industrial purchases, Mr. Sutton has been a buyer for Republic for the last 13 years.

• **John O. Chesley**, head of the sales development division, has been named railway sales manager for the railroad field of Aluminum Co. of America, Pittsburgh, and **Frank C. Barrows, Jr.**, of Detroit, has been appointed automotive sales manager for the automotive field.

• **Fred Ingraham**, who after more than 50 years' association with the American Steel & Wire Co., U. S. Steel subsidiary, is retiring as manager of operations of the Chicago district. **Harry H. Lumley** has been named Chicago district manager to succeed him.

• **Herbert J. Rosen**, for more than nine years operating manager of Griffin Wheel Co., Chicago, has been elected a vice-president. He recently was elected a director.

• **Harry Hanson**, secretary and assistant treasurer of Griffin since 1940, has been elected treasurer succeeding **Metzger D. Stinson**, retired.

• **Joseph A. Voelker** has been elected sales vice-president of Pittsburgh Steel Co., Pittsburgh. He was general manager of sales since May, 1942.

• **Paul W. Butz** has been appointed district manager of sales for Columbia Steel & Shafting Co., Detroit office.

• **Vincent K. Alexander** has been appointed sales manager of Manheim Mfg. & Belting Co., Manheim, Pa. For the past ten months, Mr. Alexander has served as acting sales manager.

• **Thomas Coyle**, chlorine products manager of the electrochemicals department of E. I. du Pont de Nemours & Co., was elected president of the Compressed Gas Manufacturers Assn., Inc.

• **William J. Heckmann** has been made general claims attorney for the Illinois Central Railroad, with headquarters in Chicago, to succeed the late Philip M. Gatch.

• **Frank J. Kane**, former superintendent of Republic Steel Corp.'s ore mine at Mineville, N. Y., has been appointed general superintendent of Republic's ore mines, Southern division.

FRANK C. BARROWS, JR., automotive sales manager, Aluminum Co. of America.

• **W. H. Jackson,** assistant superintendent, Norfolk and Western Railway, Roanoke, Va., scioto division, at Portsmouth, O., has been transferred to Bluefield, W. Va., as assistant superintendent of the Pocahontas division. **F. E. Taylor,** terminal trainmaster at Cincinnati succeeds Mr. Jackson and **A. E. Johnson** succeeds Mr. Taylor.

• **S. F. Briggs** has been reelected chairman of the board of Outboard, Marine & Mfg. Co., Milwaukee, and other officers chosen were: **Ralph Evinrude,** president; **J. Stern,** executive vice-president; **Hugo Biersach, W. C. Clausen, F. T. Irgens, E. H. Millet, J. G. Rayniak** and **P. A. Tanner,** vice-presidents; **H. M. Fisher,** secretary-treasurer, and **C. Rudie,** assistant secretary-treasurer.

• **E. J. Harrington,** former production and materials coordinator for the Lockheed Aircraft Corp., has been made a vice-president of Curtiss-Wright Corp., in charge of materials control.

• **N. B. Dinkel** of Alameda, Cal., is to represent the Crosley Corp. in the Pacific Coast area.

• **William I. Burt** has been appointed general manager of plants in the chemical division of B. F. Goodrich Co., Akron, Ohio; **Dr. Frank K. Schoenfeld** has been made director, technical and development, and **Harry E. Foster,** general auditor.

• **Edward W. Campion** has been elected chairman of the board of directors of Bonney-Floyd Co., Columbus, Ohio.

• **T. Rideout,** formerly development engineer of the gear division of Western Electric & Mfg. Co., Pittsburgh, has joined the staff of Watson-Flagg Machine Co., Paterson, N. J., as project engineer. For many years Mr. Rideout was chairman of the general standards committee of the American Gear Manufacturers Assn.

• **Robert Wier, Jr.,** has been appointed sales manager of the Winchester Repeating Arms Co., East Alton, Ill., division of Western Cartridge Co., as sales manager of the ammunition division of the parent Western organization. In his new position, Mr. Wier will direct and co-ordinate sales activities of both Western's ammunition division and the Winchester division.

GEORGE A. WHITEHURST, supervisor, administration planning, Carnegie - Illinois Steel Corp.

• **George A. Whitehurst,** formerly assistant to chief engineer, has been appointed supervisor, administration planning, for Carnegie-Illinois Steel Corp., Pittsburgh. He will coordinate policy and procedure throughout the company. Mr. Whitehurst has been associated with the corporation and its subsidiaries in various capacities in New York, Chicago and Pittsburgh, since 1931.

• **Howard G. Jones** of the Vulcan Iron Works of Wilkes-Barre, Pa., has been made New York representative. Mr. Jones, who has been connected with the home office in responsible capacities for nearly 20 years succeeds **Thomas MacLachlan** who recently resigned.

• **J. P. Lawrence,** formerly vice-president and general manager of the American MonoRail Co., Cleveland, was made president following the retirement of **H. M. Miller,** who is now chairman of the board. Other officers are: **F. C. Harris,** vice-president and chief engineer; **C. deV. Miller,** vice-president and sales manager; **J. L. Pischke,** secretary and treasurer.

• **Walter C. Ahlers** has been advanced to the position of Detroit district manager of the SKF Industries, Inc., Philadelphia, to succeed **Robert H. Hirsch,** resigned.

• **W. T. Darcy** has been appointed manager of service shop sales at General Electric Co. It is Mr. Darcy's responsibility to supervise and coordinate the repair and renewal parts business-building activities of G-E service shops all over the country.

• **Merle Thorpe** has been elected to the board of the Cities Service Co., New York, and has been appointed director of business development. Mr. Thorpe, who is retiring as editor and publisher of Nations' Business magazine, will assume his new duties immediately.

• **Adolph Frankel** has been appointed manager of the electronic tube sales department of the Westinghouse Lamp division with headquarters at Bloomfield, N. J.

OBITUARY...

• **Maj. W. E. Hoke,** 78, inventor of the "Hoke Blocks," precision gages which have remained unsurpassed for 27 years, died recently at his Baltimore home.

• **Edmund J. Walsh,** vice-president of Chattanooga Boiler & Tank Co., died Jan. 10.

• **James A. Nolan,** 54, New York State representative of the Carpenter Steel Co., Reading, Pa., died Jan. 17, at Rochester, N. Y. He was associated with the company for 33 years.

• **Frederick J. Macwilliams** of Chicago, Ill., died Jan. 23, following an extended illness. Mr. Macwilliams, 49 years old, was one of the founders and was general manager of Abart Gear & Machine Co.

• **John R. Pill,** land agent of the Woodward Iron Co., Woodward, Ala., for the last 17 years, died Jan. 28, at Birmingham. He was 77 years of age.

• **Howell G. Heddinger,** vice-president and district manager of Hedge & Mattheis Co. and formerly associated with the Wells Construction Co. and Aberthaw Construction Co. died recently. He was 57 years old.

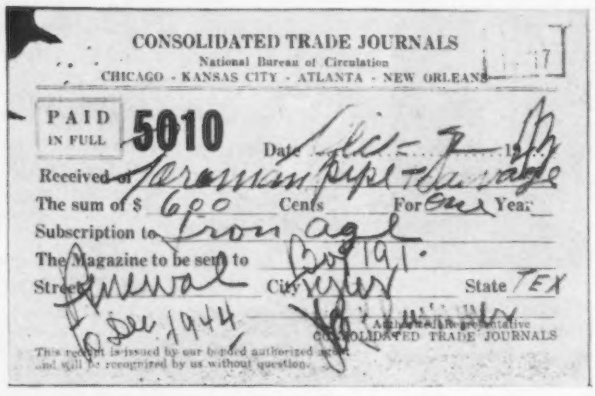
• **William M. Byrd, Jr.,** president of the Alabama Pipe Co., Anniston, Ala., died at Birmingham, Jan. 30. Mr. Byrd, who took part in founding the company, had served as president since June, 1942. He was 69 years of age.

Fatigue Cracks

BY A. H. DIX

Bargain

• • • If a sharp featured, reddish blonde, big-nosed smooth talker asks you to pay him for a subscription for your favorite family journal, better say no. The Forman Pipe & Salvage Co., Tyler, Tex., said yes and has nothing to show for it but this receipt:



CONSOLIDATED TRADE JOURNALS
National Bureau of Circulation
CHICAGO - KANSAS CITY - ATLANTA - NEW ORLEANS

PAID IN FULL 5010

Date Dec 7 19

Received of Foreman Pipe & Salvage

The sum of $ 6.00 Cents For One Year

Subscription to Iron Age

The Magazine to be sent to

Street Renewal City Tyler State TEX

To Dec 1944

CONSOLIDATED TRADE JOURNALS

This receipt is issued by our bonded authorized agent and will be recognized by us without question.

The signature reads "J. E. Plummer," who, the receipt assures us, is the "bonded authorized agent" of the Consolidated Trade Journals. But the Consolidated Trade Journals has not passed along to us the $6 its bonded, authorized agent collected, and as it is not listed in the telephone books, Mr. Plummer may be its entire staff.

Besides, the price is $8 a year, and it is safer to send it to us than to trust big-nosed smooth talkers.

Letdown

• • • Speaking of telephone books, an advertising agency man told Tom Lippert, second chair in the brains department, that of the dozens of associations listed in the New York telephone book, one is brazen enough to call its simply "The Association." We looked it up and sure enough there it is, just "The Association —Regent 4-1500."

We wish we had stopped there for then we could have treasured this as an example of arrogance magnified to an awesome degree. But we gave in to the temptation to dial the number and a young lady told us it is simply an abbreviation of "Professional Service Credit Association," which will shortly be out of existence. The number will be dropped in the next directory.

C. I. Champion

• • • For using some such simile as "brittle as cast iron," a non-technical publication had its knuckles rapped by the Gray Iron Founders Society. As the statement is not only derogatory but untrue as well, the rebuke was deserved.

What we would like to know how far it is permissible to go without getting on the Society's black books. Is it, for example, all right to say "I like your cast iron nerve?" Here, it seems to us, the reference is definitely flattering, in that indestructibility is implied.

Does the Copper & Brass Association object to "He had an infinite amount of brass" where non-ferrous stocks are not involved? And is the Lead Association sensitive to the use of its product's name in a picturesque objurgation conveying contempt for inaction?

Aptronym

In Newark, N. J., there is a Dr. Ill, also a Dr. Lancit.

—L. W. Smith,
H. & O. Machinery & Engineering Co., Newark, N. J.

Sermon for Today

• • • We have been permitted a sneak preview of an entry in the Pabst postwar employment contest, and in it find this:

> The problem will demand constructive treatment to re-establish the mutual confidence of labor in management and management in collective labor representation.

This sounds pretty, but it implies a past period of harmony, and if we were a Pabst judge we would mark this paragraph "When was this?" There never was a golden age, and while it is pleasant to hope that some time there will be, we know there cannot be. For if buyer and seller always saw eye to eye the stimulus that makes the competitive system click would be missing. The trick is to keep the friction within reasonable limits, but the only place it is completely absent is in the graveyard. Sustained harmony is much like the first stage of stagnation.

And while we are up on our soapbox we would like to issue a general bill of complaint about those who think that the hard-muscled, fat-free frame of free enterprise can be maintained without the sweat and buffeting of competition. The roadwork and weight-lifting cut into the pinochle sessions but so far they are the only known preventive of flabbiness.

So. Calif. Has One

A. B. Farquhar Co., which just dropped its distinguished "Ltd." for a dime-a-dozen "Inc.," was not the last of the American "Ltd.'s." There is Morey & Jones, Ltd., Los Angeles.

—Wm. M. Siesel, Trenton, N. J.

No More, No Less

> You refer to your brains department's use of "unwater" instead of "drain." "Dewater" and "unwater" are good old engineering terms, and are as distinctive to the specialists who employ them as the difference between "pathogenic" and "parthenogenetic" in the obs. ward.
>
> Why has your page just 18 readers? Is there some mystic virtue in the "18"?
>
> *—H. F. Cotter*

It is something that was ordained, like eight rows on an ear of golden bantam.

Sales Asset

• • • The office of one of the Pittsburgh draft boards is on the corner of Forward and Shady Avenues. The address is wasted on a draft board but for another business we can think of it would be a sales asset.

Turkey in the Shop

Congratulations to J. R. Williams on his seasonal touch in "The Bull of the Woods" of Jan. 13.

I have outlined the turkey.

—Harold J. Roast, Montreal

"MACHINISTS W

Puzzles

Last week's gambler started out with $281.25.

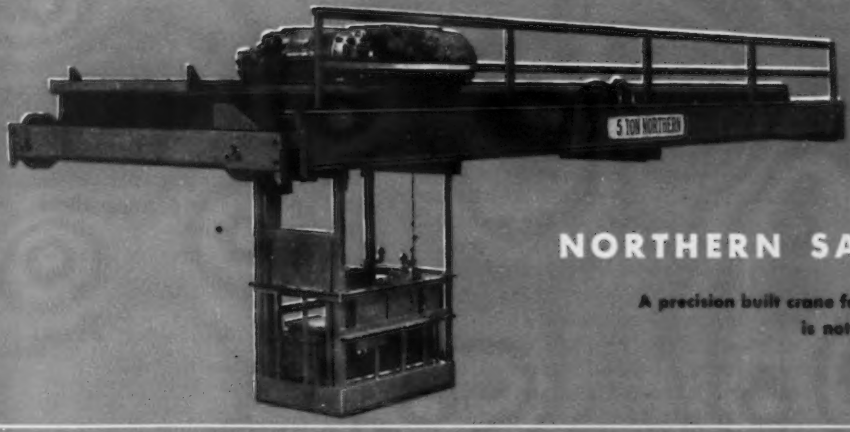
Lt. Com. A. R. Simpson aims this at the master minds. You can establish your own par:

At 12:00:00 o'clock the three hands of a chronometer equipped with sweep second-hand are in coincidence. At what other time will they exactly coincide again? If at no other time, at what time will the three hands be closest to exact coincidence, and what will be the angle of arc between the two outermost hands at this instant?

3 LINES OF *Northern* CRANES

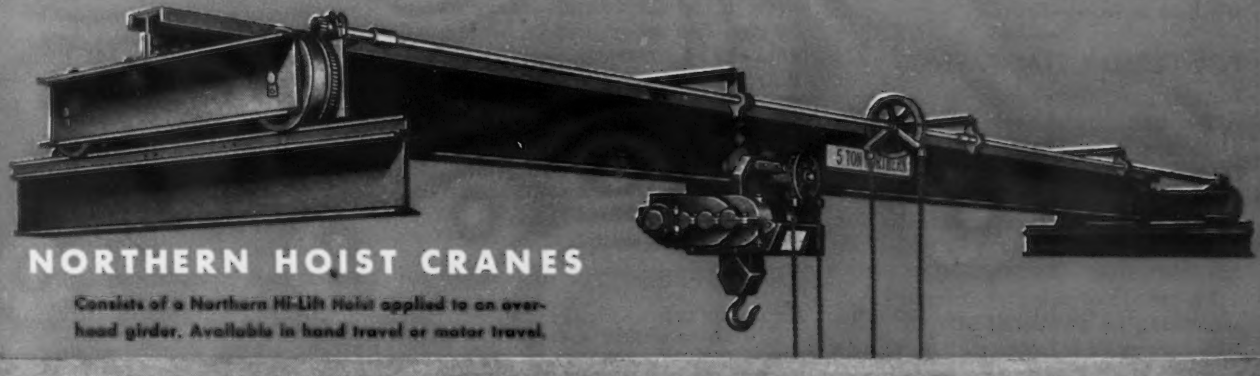
NORTHERN SUPER-CRANE

The fine machine tool of overhead cranes built for heavy duty, 24-hour-a-day jobs.



NORTHERN SA & LSA CRANE

A precision built crane for medium duty where service is not so severe.



NORTHERN HOIST CRANES

Consists of a Northern Hi-Lift Hoist applied to an overhead girder. Available in hand travel or motor travel.

Northern
ENGINEERING WORKS

General Office: **2613 Atwater St., DETROIT, MICH.**

All Northern Cranes are built to the most modern standards — are especially sturdy, durable, and have the most modern electrical equipment and control. Trolleys are one-piece welded construction. Gears are precision machine cut, and run in an oil bath. Ground shafts operate in oversize roller bearings. Construction is *right* throughout.

A Northern Crane, properly selected for the job, will give long, satisfactory service.

Write for booklet.

Dear Editor:

SEIZED PATENTS CHAMPION

Sir:

Evidently Mr. Tolley (Dear Editor page Jan. 6 issue) is disappointed because he hasn't arrived at that Big Rock Candy Mountain. He has looked up 30 enemy patents and has found nothing of value. Where will he ever find any list of patents that assays better than one per cent, to say nothing of three per cent as he demands?

In stating that most patents of value have probably already been culled, he overlooked the fact that the same privilege accrues to him, as the manufacturing rights are nonexclusive. I feel these lists have great potential value but the labor of separating the wheat from the chaff appears enormous. Why don't you and your able staff of brain trusters tackle that job some day in your spare time?

HENRY F. GASTON,
Industrial Engineer
4306 51st St.,
Hyattsville, Md.

● We have already culled out the seized patents covering metal products and processes, but do not feel competent to do a further job of separation as one man's wheat is another man's chaff.

Not all seized patents listed are available for licensing. The Alien Property Custodian informs us that licenses are not available for those patents on which pre-war licenses were granted, for these arrangements still hold in force.—Ed.

POWDERED METAL PATENTS

Sir:

We have purchased three albums from the Alien Property Custodian, listing thousands of patents. They are so poorly listed, as to field the patents cover, that it is practically impossible to find a patent in which we are interested.

Do you have a better compiled list, something on powdered alloys?

SPECIAL MACHINERY BUILDER
Indiana

● Powdered metals patents are included under the APC "Metallurgy" classification. This class has not yet been covered in The Iron Age series on seized patents, but will be soon. Our series, while describing the patents in greater detail than the APC albums, follows the same broad classifications. Therefore, the nuggets, if there at all, are not found without some spadework.—Ed.

TOOL STEEL DIRECTORY

Sir:

I had the opportunity of glancing through your Tool Steel Directory. Will you please forward six copies with bill.

CHARLES G. GRAZIOSO,
Chief Engineer,
Artillery Engineering Dept.
Frankford Arsenal,
Philadelphia 37

● Prices are: Single copies, $1; five or more, 50c each.—Ed.

FIBERGLAS

Sir:

A local firm telephoned us in an effort to locate a rather elaborate table having to do with synthetic fibers, plastics, etc., which the firm recalled as having been in a June or July issue. We can't find it. Did we publish it?

CLEVELAND OFFICE

● See "Physical Properties of Fiberglas Laminated Plastics," July 22, 1943 issue.—Ed.

INFRA-RED RAYS FROM GAS

Sir:

An inquirer about the use of infra-red rays for the drying of molds in a steel foundry was referred, in the Dear Editor page of Jan. 20, to a maker of electric infra-red lamps.

Infra-red radiation is emitted by any hot source regardless of how the heat is derived. Even the wave length of the emitting body behaves on the basis of the temperature of the body and not on the basis of the manner by which that temperature is reached. A test recently made by Rolls-Royce in England, to determine the relative mold drying efficiency of a gas-heated medium temperature infra-red radiant energy source, compared with a standard infra-red radiant unit, produced results that were quite startling in the decided advantage offered by gas. The report will be made available at the American Gas Association War Conference on Industrial and Commercial Gas to be held in Rochester March 30 and 31, 1944.

C. GEORGE SEGELER,
Engineer of Utilization
American Gas Association,
420 Lexington Ave.,
New York 17

ZAY JEFFRIES

Sir:

I wish to obtain a copy of a paper by Jeffries published in IRON AGE during November, 1934. Can you identify the author?

K. SPROULE
Box 547,
Copper Cliff, Ont.,
Canada

● The article, "Nonferrous Metals—Past and Future," began on page 20 of the Nov. 8, 1934 issue. Its author, Zay Jeffries, well-known Aluminum Co. of America metallurgist, may be addressed at 2210 Harvard Ave., Cleveland.—Ed.

SCRAP IDENTIFICATION

Sir:

It is requested that permission be granted to reproduce certain sections of the article, "How to Identify Alloy Steel Scrap," appearing in your April 16, 1942, issue. If permission is granted, the material will be used in a paper to be written for the Ordnance Sergeant, a magazine published by the Ordnance School, Aberdeen Proving Grounds, and disseminated to Ordnance technicians engaged in field maintenance.

W. T. MAINWARING, 1st Lt.,
Ordnance Department
96th Ordnance Maintenance Co.,
Ry. Arty.,
14th Ordnance Maintenance Bn.,
Fort Monroe, Va.

● Granted.—Ed.

HIGH SPEED MILLING

Sir:

Will you kindly send us reprints of your article, "High Speed Milling in Aircraft Production," and also "Report on the ASME Special Meeting on High Speed Milling."

KARL H. WHITE,
Chief Draftsman
United States Navy Yard,
Naval Aircraft Factory,
Philadelphia

AIR-OPERATED PRESSES

Sir:

We are interested in buying some small bench type presses to be operated by air, and which should be suitable for cutting paper, celluloid, or thin plastic, and real light metal, from special dies.

Could you provide us with the names of manufacturers of this type equipment?

CARLYLE E. ANDERSON,
President
Monogram Glass Co., Inc.,
1131 Chicago Ave.,
Evanston, Ill.

● A few of the firms making small bench type presses operated by air are Hanna Engineering Works, 1765 Elston Ave., Chicago, Ill.; Hannifin Mfg. Co., 621 Kolmar Ave., Chicago, Ill., and F. J. Stokes Machine Co., Olney P. O. Philadelphia, Pa.—Ed.

PLASTICS AND PLASTICITY

Sir:

If available, will you kindly send us two reprints of E. V. Crane's series on "Plastics and Plasticity," which appeared in your issues of July 29, Aug. 5, 12, 19 and 26.

G. N. DONOVAN,
Librarian
Western Electric Co.,
100 Central Ave.,
Kearny, N. J.

● A reprint of the series may be obtained by writing to the author E. V. Crane, Chief, Development Engineering Department, E. W. Bliss Co., 53rd & 2nd Ave., Brooklyn, N. Y.—Ed.

PRIORITIES GUIDE

Sir:

We have the 7th edition, October, 1942, of your War Priorities Guide but would like to have the latest edition.

MARGARET M. MILLER,
Librarian
Standard Oil Company of California,
Standard Oil Building,
San Francisco 20

● The latest edition is the 8th, which was published as a supplement to our issue of April 29, 1943.—Ed.

THEY'RE COMING AT *You!*

First on the agenda of postwar planners is the problem of "full employment" for present workers and returned military men. These people are looking to you for jobs at today's standards of wages and living.

But you can't turn out a sufficient volume of peacetime goods at salable prices, unless you can find means to offset higher manpower rates. Prewar methods and equipment won't do it.

Much of the answer lies in better selection and utilization of machinery. You must get more production per hour than you did before the war. In this, machine tools, the cost-cutting tools of industry, will play a more important part.

During the War, machine tool builders have learned many ways to effect substantial time savings. Monarch engineers have helped many a war plant use lathes to better advantage, to get material quicker to the fighting front.

These same practical Monarch men are at your service for peacetime production. They can show you timesaving short cuts that can also be depended upon to cut costs. Full utilization of the important timesaving features of Monarch Lathes will enable you to produce more goods for more people at lower cost—and thus help you keep your plant busy and your workers satisfactorily employed.

THE MONARCH MACHINE TOOL COMPANY · · · SIDNEY · OHIO

MONARCH LATHES *Save Time*

This Industrial Week . . .

- **Steel Ingot Output Ups; January Tonnage 7,595,202**
- **Order Volume Remains High; Plate Shipments Set Record**
- **Essential Civilian Tonnages Set; More Contract Cutbacks Occur**

STEEL production continued rising this week, with a one-half point gain to 99.5 per cent from last week's revised figure. While the recognition of new capacity as of Jan. 1 will result in downward corrections by a few points for this and the five preceding weeks, the increasing trend has exceeded expectations. January total tonnage output at 7,595,202 tons was the highest since last October.

Steel order volume in general continues exceptionally high with respect to shipments. Plate deliveries which set a record last year established a new mark last month at 1,173,164 tons. High pressure output will continue for weeks to come and will result in continued tightness of steel sheets which now are extended on mill order books into the latter part of this year and in a few cases into 1945. When and if plate demand eases, backlogs on sheets may be shortened considerably.

Recent steel allocations emphasize the fact that essential civilian needs (contrasted with regular civilian manufacture) haven't been completely forgotten in the hectic rush to provide invasion equipment for the armed forces. A program which will require about 1,200,000 tons of carbon steel for farm machinery in the year starting next July 1 has been anounced. Commitments on new domestic freight cars aggregating about 28,000 cars have been made covering the first three quarters of this year. (Freight car makers, incidentally, are reported to be worried about rising costs of material and labor.) There are indications that tin mill production may be expanded substantially as the permission to make steel beer cans for off-shore and foreign consumption will require a large tonnage. The open weather has caused high demand for wire products by farmers. Oil well drilling early this year will require much steel pipe. While details regarding requirements for construction of the projected 1250-mile trans-Arabian oil pipeline which the U. S. will build have not been announced, it is reported that the main line will be built or 24 or 26-in. seamless tubing and will involve approximately 120,000 tons.

ADDITIONAL cutbacks in contracts for the production of war goods have come to light during the past week. White Motor Co.'s contract for half-tracks was cut off completely, although the service parts program will continue. Several subcontracting plants in New England stopped work. A Cleveland shell maker laid off men after its contracts had been cancelled. Steel barrel orders have been reshuffled. There were numerous other evidences of contraction over the Nation. But at the same time, several new projects were in the wind, one, for example, being a new type of shell which if it proves successful may be of interest to stamping firms.

Revisions in the Army supply program are believed likely to pressage further contract cancellations, with government-owned plants bearing the brunt of the blow ahead of private industry. Queried by THE IRON AGE as to certain phases of industrial demobilization plans, Army officials indicated that there is mounting opinion in favor of compiling a "Blue Book" of machine tool prices to be paid by private purchasers of surplus government equipment; that the military services feel they should have control of stockpiles as a protective measure against future wars; that copper, lead, and zinc stockpiles should be increased; that there is no need for stockpiling scrap; that weapons of proved obsolescence will not be stocked.

Probable postwar consumption of steel in the far west is a lively topic now, particularly in relation to the capacity of steel mills in those states. A number of market analysts have been exploring the subject in detail with varied results. The McCarran committee on decentralization may develop much discussion.

ESTIMATES of postwar consumption range from a gain of 400,000 tons over the pre-war era in eleven western states to a 1,000,000-ton increase. The Kaiser interests are reported to have been particularly active

50,000 Tons of Aluminum for Mats

WASHINGTON

• • • Assistant Director of the Aluminum and Magnesium Division Thomas E. Covel said on Wednesday of last week that the division has allotted 100,000,000 lb. of aluminum to the Army for making landing mats.

Mr. Covel told THE IRON AGE that several different types of sheets are being experimented with, and that the huge order could be placed by the Armed services over whatever period of time deemed most desirable. It is understood that preliminary tests of aluminum for landing mats have run into forming difficulties, but that the Army has not reached any conclusion regarding the suitability of aluminum alloy mats.

The division has placed the total supply of aluminum at more than 2,000,000,000 lb.

Aluminum supplies include 250,000,000 lb. of primary metal and 75,000,000 lb. of secondary metal held by Metal Reserve Co. and additional 750,000,000 lb. of privately-owned ingot.

Steel Market Briefs

• PRODUCTION—Steady at high levels. Present rate assured as long as flat rolled demand holds up. Completion of European phase of war expected to cause temporary decline. Repairs may cause some slight leveling off.

• DISTRIBUTION—Product mix still unbalanced, due to flat rolled demand. Headaches ahead for WPB, as long as steel supplies for war exceed demand.

• PRICES—Steady on major products. Mills with higher than ceiling prices approved by OPA losing out, where items are obtainable elsewhere at ceiling prices. OPA in last stages of analyzing cost data from all steel companies on carbon steel products.

•FLAT ROLLED STEEL—Tight, and getting tighter. Plate deliveries going into third and fourth quarter. Sheet deliveries into third quarter, with some promises being made for early 1945. Shipbuilding program mainly responsible. Relief on plate demand may occur by July. Landing craft program will run until September. Sheets needed for expanded landing mat program. Barrel program cut, but some orders may be reinstated on sheet mills.

• BARS—Some sizes in good demand. Mix not very good. Hot rolled bar trend slowly downward, until WPB opens up on civilian steel. Cold finished bars very active in the last two weeks, due to resumption of certain shell and bomb programs.

• PIPE—Tight all along the line. Under CMP, oil companies getting break for drilling material. Plenty of oil country pipe available, but drill pipe quite tight.

• TIN PLATE—Second quarter tin mill production will be more than 100,000 tons above first quarter. Third quarter even better.

• MISCELLANEOUS—Wire and wire products in good demand. Farm repairing continues at accelerated rate. ALLOY steel demand off sharply. Electric furnaces being curtailed. PIG IRON—Easy, with DPC blast furnaces being shut down, indefinitely. This situation mitigates possibility of grave scrap outlook. SCRAP quite easy. Major items still selling at OPA ceilings. Future price trends on some items, such as turnings, may be downward.

in making surveys, which are said to show larger potential postwar consumption than previously thought likely.

Kaiser, recently urging his steel workers on to lower cast production because "we can expect keen competition within the very near future and that prices will decrease," explained that his plant is wholly owned by Kaiser Co., Inc., which company is in turn indebted to the Reconstruction Finance Corp. for funds borrowed. "We are paying interest at 4 per cent," he said, "and have pledged collateral for its payment. Part of this collateral is in the nature of ship earning fees which the shipbuilding division of the Kaiser Co., Inc., is earning."

To prepare steel consumers for possible price revisions, OPA administrator Chester Bowles stated last Friday that there might be price increases in some products and decreases on others. No across-the-board action, blanketing all steel products, is contemplated. In some quarters, the Bowles statement was interpreted as a tipoff that the steel industry will not get as wide scale an increase as it might have expected, but producers generally remained confident that cost data which has been submitted amply support the need for higher prices in certain items, notably rails and semi-finished. OPA is making the most complete survey ever attempted of steel industry costs.

MARITIME Commission plans for disposing of its surplus materials are being followed with interest because of the large quantities that may be involved. Recently Maritime scrap has been moving to the middle west from the Pacific Coast in large quantities, said to total around 100,000 tons. Other high spots in excess and idle steel circles include a reported gain in exports of this material and a report that warehouses are not buying heavily because of the dissatisfaction with M-21-b-1 governing purchases and sales. Most of the excess steel problems are mild, however, compared to the excess tool steel dilemna where a wide variance of sizes and compositions makes disposal difficult.

FOR BEST RESULTS On "Poor Fit-Up" Jobs

Use Raco 8 Shielded Arc Electrodes

Bridging wide gaps in poorly fitted joints is work just "made" for Raco 8's, because these Electrodes are versatile. They produce excellent multiple pass, high tensile medium ductility welds in all positions. Furthermore, though Raco 8 Electrodes give best results with direct current, straight polarity, satisfactory welds can be made with reverse polarity and with alternating current. Try Raco 8 Electrodes on your "Poor Fit-Ups." You'll be rewarded with faster, better production, lower costs.

Raco 8 Electrodes comply with all these specifications:

A.W.S.—A.S.T.M. Specification A233-42T, Type E-6012.

A.S.M.E. Boiler Code, Para. U-70.

American Bureau of Shipping, Grades H1G and B2G (A.C. or D.C.)

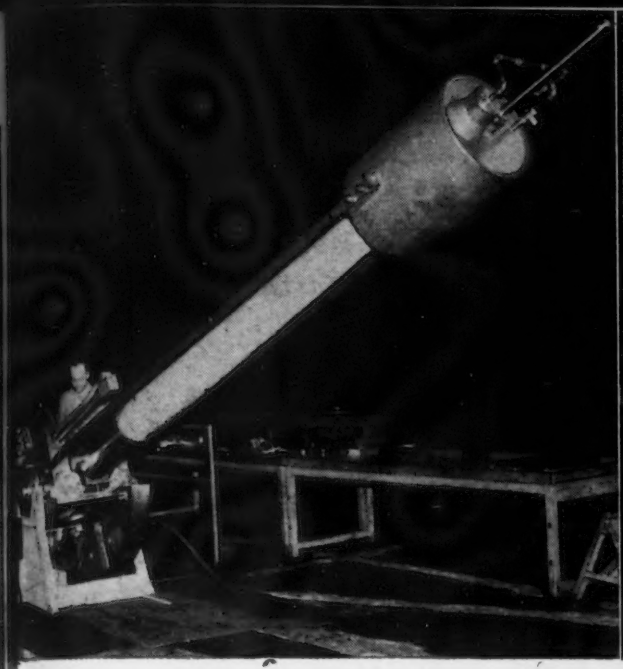
Dept. of Commerce, Bureau of Marine Inspection and Navigation.

★

Use Raco 82 Electrodes for building up worn parts and surfaces of medium-carbon steel. Welds are machineable.

The REID-AVERY COMPANY

DUNDALK BALTIMORE 22 MARYLAND



General Rise in Steel Prices Not Warranted, Bowles Asserts

Washington

• • • **In an unexpected** statement issued last Friday, OPA Administrator Chester Bowles asserted information now in the hands of OPA indicates that no general steel price increase is justified. Further, he indicated that there might be some increases on particular products and actual decreases on others. He hastened to point out, however, that no decision will be made until OPA has concluded its survey of the steel price structure.

That the Price Administrator discussed the comprehensive study now under way in advance of action on it created considerable comment and was interpreted in some quarters to be a tipoff, guarded as it was, that the steel industry will not get as wide scale an increase in prices as had generally thought to be probable. There also was speculation that the statement was partially directed against wage-increase demands of the CIO-USW, at least against the sharp increase labor is asking, 17c. an hour.

In pointing out that OPA is making the most complete survey ever made of steel industry costs in cooperation with its Steel Mill Products Advisory Committee, Mr. Bowles said that it covers 90 per cent of the industry tonnagewise and all major carbon steel products. A parallel study, he said, of alloy steel products is about to be undertaken by OPA and its Alloy Steel Advisory Committee. At the earliest, he added, the survey and analysis will not be completed before March. This latter committee will meet with OPA late this week.

The present study covers financial data from 1936 to date in addition to steel mill cost analyses for November, 1943. OPA has comparable mill cost data for the early part of 1942 as a result of an earlier but less intensive survey, it was stated.

"It appears from the limited information currently available to us that the steel industry does not at present need a general upward price adjustment," Mr. Bowles said. "No decision will be made before the studies are completed.

"Whether or not particular steel mill products will be shown to need price increases or price decreases, and the extent of such price increases or price decreases simply cannot be ascertained in the present stage of study. At the earliest, the survey and analysis will not be completed before March.

"Furthermore, should the results of the survey indicate that some costs have increased above realization while costs of some other products have gone down, it may be possible to balance some individual ceiling increases against other decreases."

Expressing a view that is in contrast with that widely held by economists both within and outside of the government, Mr. Bowles does not accept the steel industry as the bellwether of the economic structure. On the contrary he treats each basic industry separately in that a price increase in one does not lead under wartime control to a price increase in another. Such price increases are referred to as only "speculative influences."

o o o

Figures Will Support Adjustment

Pittsburgh

• • • **Close reading of** Price Administrator Chester Bowles' statement regarding the possibility of a steel price rise indicates that, despite popular press interpretations, there is a good chance that adjustments in the price level of the majority of carbon steel items can be made. Certainly the feeling in this large steel center is that there can be no final decision until the data sheets, now in the hands of OPA, can be adequately studied.

It is known that data on many carbon steel items is such that costs figures will support some sort of upward adjustments. Nor is it improbable that some of the revisions might not be substantial—especially on those

AT TWO WAR GOODS PLANTS: *Photo at left shows testing of 5-in. Naval gun without firing it, at Fisher Body Pontiac Division. At right: transfer of propeller blades from furnace into hydraulic press at Curtiss-Wright Corp.*

products which for months have shown an actual loss. The reference to a "general price adjustment" is of course not consistant either with the facts or with the special conditions with which the industry has been confronted in the past year or so.

The fact that in an unprecedented move the steel companies have furnished cost data which previously has been largely confidential, indicates that there is support to the realistic belief that some form of price adjustments will be made on many steel items. Furthermore the OPA made its own studies months ago which pointed to the need for a complete overhauling of the steel price structure.

It is a matter of record as to the increased costs which have confronted the steel industry. Raw material costs, freight rates and labor increases have all accumulated to such an extent that the volume of orders, better freight returns, allowable extras, and a good product mix in the early stages of the war are not now offsetting high cost handicaps. It is for this reason that the industry threw overboard its age old reticence to government scrutiny of its most private costs data.

Probably one of the first items which may be advanced under OPA approval will be steel rails. For years the industry has more or less made this product at either a break even point or at a loss. Not so many years ago rails were picked as a political focal point to indicate a reduction in steel prices. Nonetheless at least one steel company has been able to prove to OPA that it should get $5.00 a ton premium on standard rails.

Other items which will certainly stand a chance of an increase in price will be ingots and semifinished steel. Ingots in many cases have been made and shipped at a price that was only a few cents above actual cost without some overhead being considered. Semifinished steel such as sheet bars and slabs have been made and shipped at little or no profit.

Finished steel products will probably take a longer time to process and will lend themselves to a lesser degree of adjustment than products such as ingots, semifinished and rails.

WPB Vice Chairman Named

Washington

• • • **Wade T. Childress** has been appointed as WPB Deputy Vice Chairman for Operations. Mr. Childress has served with WPB and predecessor agencies since May, 1941.

Postwar Steel Consumption in West Subject of Much Speculation

o o o

By DON R. JAMES
News and Markets Editor

o o o

• • • **Probable** postwar consumption of steel in the Far West is a lively topic now, particularly in relation to the capacity of steel mills in those states. A number of market analysts have been exploring the subject in detail with varied results. The McCarren Committee on centralization may develop additional discussion.

Purely for background interest, the tables on the next page (page 101) are presented, showing capacities and also an estimate of consumption in western states in 1937. Data along the lines of the latter rarely are available.

The principal increases in finished steel capacity in these states have been for the production of shapes, plates, bars and hot rolled sheets. Capacity built and building in the states under discussion now exceeds 1937 consumption in all these products except the latter product.

As to the postwar era, estimates range from a gain of 400,000 tons over the pre-war era in these states to a 1,000,000-ton increase. The Kaiser interests are reported to have been particularly active in making surveys, which are said to show larger potential postwar consumption than previously thought likely. The Kaiser firm is said to have hired a government agency, as permitted under Public Law 74, to develop some figures.

Much discussion has centered upon population changes and more will be heard in this respect. The Pacific States have shown a significant increase in population and employment since early 1940. According to a recent study by K. C. Stokes for the Bureau of Foreign and Domestic Commerce, the percentage change of civilian population between April 1, 1940, and March 1, 1943, is plus 7.3 in the Pacific States. This far exceeds any other geographic area. The only other gain is 1 per cent in the South Atlantic States. The Mountain States show a decline in population of 3 per cent in the same period, according to Stokes. The Pacific States as of March 1, 1943, had 8.10 per cent of the total U. S. civilian population and the Mountain States had 3.13 per cent.

Undoubtedly the postwar Pacific States will retain part of the wartime increase in population. Just how great the consequent increase in steel consumption will be is a matter of conjecture. According to Marion Worthing, author of the consumption figures for 1937 in the accompanying table, the Mountain and Pacific States then had 10.3 per cent of the U. S. population and took 7.1 per cent of the total finished steel.

In connection with West Coast capacity, as with other steel capacity figures, it must be remembered that capacity figures at best are rough guideposts. In a given company diversion of raw material from one type of finishing mill to another can enable a unit to produce beyond given capacity.

The two newest plants in the west are the DPC works in Utah and the Kaiser plant at Fontana, Calif. The Geneva plant is located about 45 miles south of Salt Lake City and about 5 miles from Provo. Its coal comes 130 miles, its iron 225 miles, its limestone and dolomite 25 miles. The Kaiser plant is 50 miles east of Los Angeles and its coal comes 830 miles, its iron 179 miles, its limestone only a few miles.

Geneva's two major products were to be plates and structurals, but the structural mill was ordered halted when 90 per cent complete. Construction of the Kaiser structural mill is going ahead and it is expected to be in operation next summer.

Production of steel started Feb. 3 at the DPC's $180,000,000 steel plant near Provo, Utah, with the charging of the first open hearth furnace. This is the first open hearth steel produced in Utah. This plant, the largest in the West, is operated for the United States government by Geneva Steel Co., U. S. Steel subsidiary. It will have a yearly capacity of 1,280,000 tons. This newest addition to the nation's open hearth steel capacity is one of nine 225-ton basic open hearth furnaces. Two more will be brought into production at approximately weekly intervals.

Columbia Steel Co., west coast U. S. Steel subsidiary, began construction of this, the first fully integrated steel plant west of the Rocky Mountains, in April, 1942, for the DPC.

*Less than 100 tons.

Marion Worthing is the author of the above statistics on finished steel shipments, prepared for the National Resources Planning Board. Certain statistical projections were made. In the case of an occasional item, apparently the state was credited with consuming the steel if title to the tonnage was taken in that state. The grand total for the 11 states is higher by around 500,000 tons than another similar pre-war study covering the same areas.

Maritime Sets Procedure for Disposal of Its Surplus Materials

Washington

• • • **Unified procedure** for disposal of surplus property, giving first preference in obtaining material to contractors in the shipbuilding industry, then to other government departments, war contractors, industries, reconverting to civilian production, and last to competitive bidders, has been established by the Maritime Commission.

Each shipyard is responsible for reporting to regional directors of construction on the East, West, and Gulf Coasts, and the Great Lakes area on all property in excess of the need of the particular vessel construction contract for which it was purchased.

Supplies are to be segregated at the shipyard until use or sale of unrequired property is made. When local storage facilities are overburdened, material may be shipped to Maritime Commission warehouses, after consideration of handling and transportation costs. If material can be used on other shipyard contracts, it will be allocated, obviating purchase of new material. Before any requisitioned material is purchased for contracts, unrequired property inventories will be consulted.

In cases where unrequired material may be available which does not meet exact specifications of current or anticipated construction requirements, the Technical Division of the Commission will advise whether plans and specifications can be altered to utilize the material.

When the WPB requests that available material be sold to persons or firms engaged in essential war activities, or in re-conversion to civilian production, a negotiated sale, without competition, may be authorized. Otherwise, property will be advertised for sale with invitations issued for bidding and the bids opened in public. All such sales will be conducted by the district officers.

The Surplus Property Section in Washington will issue general statements of classes, quantities, and types of materials which are available. Persons wishing to be on the mailing list for statements must list the types of commodities desired.

Warehouses Scorn Handling Excess Steel

Cleveland

• • • **Warehouse reactions** here to the presumed stimulus of the relaxation of order M-21-b-1 permitting the purchase of idle and excess steel has not been at all satisfactory from the volume standpoint. Despite the granted permission for warehouses to buy excess steel outside their tonnage and product class quotas little such activity has been noted in this market. The warehouses' reluctances appear to hinge on two deficiencies of the relaxed order.

The first and most aggravating, it is reported, is the fact that steel once placed in a warehouse stock from an idle inventory loses its identity as idle or excess thus requiring the ultimate buyer to furnish an allotment to buy. This contrasts with the fact that no allotment is required if the purchaser obtains the steel direct from the idle steel holder. This in effect eliminates the advantage to the buyer.

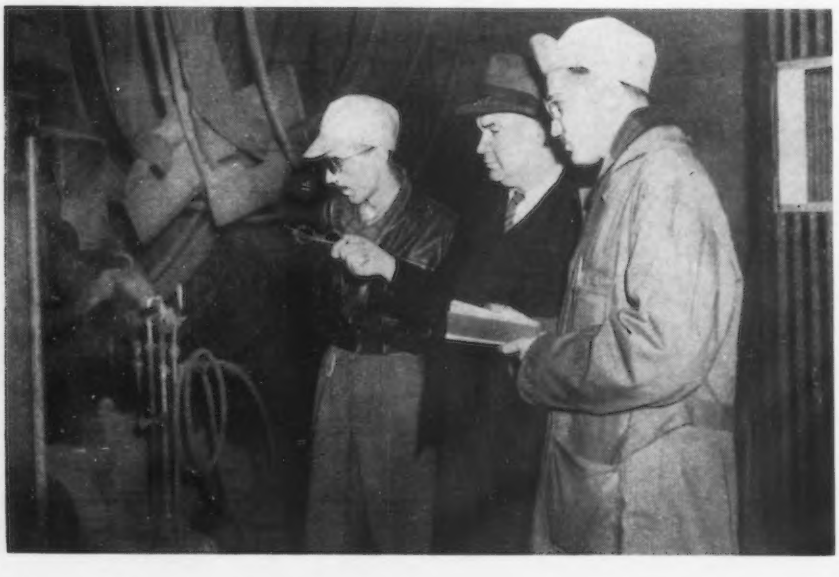
The second is that small and often new dealers, who have established themselves in business solely through a purchase of excess steel as their first inventory, are permitted by the order to replenish inventories from warehouses or distributors without allotment. This is not true of warehouses, and frequently acts as a penalty against them.

WPB, it is claimed, is reluctant to accept proposals of the warehouse industry that idle steel remain "ex-allotment" steel even though purchased by a warehouse for resale because of difficulties forseen in keeping inventories separated in warehouses. The industry claims that if steel held by warehouses as excess were to be resold against an invoice of original purchase from excess stocks, no trouble would be experienced; the identity of the steel could be maintained; and the added sales feature of ex-allotment steel from warehouses would not only work to the benefit of the warehouses but would also increase sales.

Idle and excess steel movement by the Cleveland regional redistribution facilities of the WPB have about reached the point of new listings, averaging about 15,000 tons per month. Overall inventory of idle steel for the region stands at about 35,000 tons, but records are not complete. J. J. Tice, regional manager of the WPB facilities division in Cleveland claims that warehouses are buying cautiously but in large blocks.

Plates and sheets are in heaviest demand, following the current market trend. Tool steel is in excess and moving slowly as are alloy steels. A moderate amount of exporting is moving a variety of carbon steel grades and sizes to South America and Mexico.

BRAZILIAN STUDENTS: *Under the auspices of the offie of Inter-American Training, these two Brazilian students, Joao Franca, left, and Mauricio Grainberg, right, talk with Ben Brown, melt shop superintendent at Jessop Steel Co. Both are attending Carnegie Institute of Technology, Pittsburgh, for metallurgical training.*



Rising Costs Create Concern Among Builders of Freight Cars

By TOM CAMPBELL
Pittsburgh Regional Editor

Pittsburgh

• • • **The railroad** freight car building program for the third and fourth quarters of this year may run into a snag, unless car builders are granted some form of price relief from OPA, according to reliable sources here.

Commitments on new domestic freight cars, during the first three quarters of this year, aggregating about 28,800 cars, have been made; but the substantial increase in raw material and labor costs, which have plagued the car building industry in the past few years, may act as a "brake" on the acceptance of additional orders.

Car builders, as a whole, had their selling prices frozen as of October, 1941. It is understood that substantial cost data already has been furnished to OPA by car builders, and some sort of a decision on the possibility of adjustments in freight car prices is looked for soon. Meanwhile, in addition to absorbing increased costs, to the limit of its ability, the car building industry also faces the prospect of higher steel prices this year.

If steel price adjustments, upward, are made on those products going into car building, and if such increases are made retroactive by OPA, the car builders face, it is said here, a condition which certainly will require help from the OPA. The car building industry, like other industries, whose prices have been frozen, has had increased raw material costs as well as increases in basic labor rates. Added to this have been higher costs, induced by labor strikes. In some instances, car builders have also had to pay more than the usual freight on their raw materials, due to the necessity of taking material from those suppliers directed to ship it by WPB.

For the first quarter this year, orders for about 10,000 domestic freight cars have been placed, and a like number have been accepted for the second quarter. Out of an estimated 10,000 domestic freight cars to be ordered for the third quarter, commitments have been made for about 8800.

The War Department's railroad car orders of last fall, which amounted to about 40,000 cars, have been revised to the extent that about 5500 have been cancelled. It is understood, however, that 2000 may be reordered. There are rumors to the effect that the War Department may make substantial additional purchases late this year, although such an action is entirely dependent upon the course of the war.

o o o

Farm Machinery Quotas for 1944

Washington

• • • **Two schedules** governing farm machinery production for the year beginning July 1, 1944, were issued by the WPB this week. Production volume authorized is about the same as for the current year, but schedules may be altered between now and July 1.

The schedules permit manufacturers to plan production and order materials under CMP provisions. Changes in the distribution pattern now set up or the addition of controls or exemptions are not expected to reduce the total volume of machinery to be produced. The program will require about 1,200,000 tons of carbon steel and more than 1,000,000 tons are earmarked for the American farmer.

The tentative breakdown of this steel is: 88 per cent for the domestic

Farm Equipment Production Down in 1943

• • • A decrease in both quantity and value of production of tractors, harvester-thresher combines, and grain threshers in 1943 as compared with 1942 was announced by the Bureau of the Census, Department of Commerce. Total production of tractors (agricultural, industrial, and military) in 1943 amounted to 137,591 valued at $196,247,958; combines, 30,377 valued at $17,294,010; and grain threshers, 694 valued at $469,699.

* Preliminary figures subject to revision.

farmer; 5 per cent for military and industrial needs; and 7 per cent for export.

Quotas are determined, as in the basic order L-357, by taking a percentage of the net shipping weight of machinery in any given category produced in 1940 or 1941. A manufacturer may choose either year as his base period, and he may "bracket" his production in any given group or division of machines. Quota percentages for 400 kinds and types of machines are given in Schedule B or order L-257. This schedule B corresponds to schedule A in effect at present.

Production quotas for export, except to Canada, are based on net shipping weight of machinery, equipment, and spare parts shipped to the countries or groups of countries listed in seven different schedules. In all but one of these groups of countries, the quota is based on a percentage of one half of the total net shipping weight of shipments made in 1940 and 1941 to all of the countries in the group. In the seventh group, schedule X-17 of L-257-a, each country must be taken separately. The quota percentages in this group vary widely.

Exports to Canada are dealt with in a separate schedule, X-18. Quotas for complete units are not based on weight but on the number of units of items; those for attachments and repair parts on net shipping weights.

Schedule X-12 lists 57 countries and areas for which the quota is nil. This list includes France, Norway, Poland, the Netherlands, Denmark, Belgium, and Italy.

Revised Army Supply Setup Points to More Contract Cutbacks

By DONALD BROWNE
Washington Staff

• • • It is expected that substantial contract cancellations in addition to the $8,000,000,000 previously announced will be made as a result of recent revisions of the War Department's supply program.

According to the War Department, it is following a policy of terminating contracts in government-owned plants instead of in privately-owned plants primarily to keep American industry on a going basis as long as possible. At present the termination of war work in private plants would result in these plants becoming idle, since manpower and critical components are not available in sufficient quantities to permit the resumption of civilian production, the War Department says. When the materials and manpower suffice for this purpose, the War Department would then change its policy to keep government-owned plants in operation to the fullest extent possible so that private industry could resume its normal production.

An inquiry on War Department industrial demobilization plants recently made by THE IRON AGE brought the following answers with respect to:

Machine Tools—There is mounting opinion that the government should compile a "blue book" of machine tool prices to be paid by private purchasers of surplus machine tools owned by the government. The thought is that companies desiring tools for peacetime production should be permitted to purchase surplus used tools now at appropriate discounts off the first cost to the Government.

In this way, actual savings to the government would be effected, it is said, because manufacturers are reluctant to buy used tools under present regulations where the price is generally set by rather conservative depreciation rates. It is pointed out that companies will prefer to buy new tools if high prices are demanded for used ones.

Thus contracting officers would have a protective guide in the sale of tools and could not sell below the minimum when special permission was granted by higher authority.

In general, the War Department proposes to stock special purpose tools of military significance but for which there is no civilian or peacetime use and wants also to modernize completely the tooling of government arsenals. The remainder under this plan would eventually be declared surplus and sold.

Work in Process—A considerable portion of work in process may well be used to expedite the completion of civilian type end items during the period of transition from war to civilian production. Some will be used for the production of replacement parts which may be finished when the demand is sufficient. The balance would find its way to the scrap pile.

Replacement Parts—Practically the same formula as applied to machine tools may be followed with regard to replacement goods, except there is no "blue book" plan afoot. The War Department will reserve the number of parts needed to maintain airplanes, automotive and other equipment it owns for the life of this equipment. The remaining parts will be sold as surplus or disposed of as scrap.

Strategic Stock Piles—It would appear that the military services believe they should have the responsibility for the determination of stock piles of critical materials to be established as a protective measure against future wars. It is also understood

SECRET WEAPON: *This is the M-8 motorized weapon carrier, made by Cadillac Motor Car Div. of General Motors Corp. It mounts a 75 mm. howitzer and a 0.50-cal. anti-aircraft gun in its open turret, making it a weapon complement for the 37 mm. fire power of the M-5. The new vehicle is especially adapted for mountain fighting.*

that the services desire to start this stockpiling by being authorized to take over stock piles in existence at the end of the war. Manifestly, such authorization would allay the fears of industry that these stock piles would destroy the immediate market.

The War Department is not ready to concur in the reduction of the production of copper, lead and zinc until present stock piles have been materially increased, nor to change the detail of soldiers furloughed from the Army to work in the mining of critical non-ferrous metals, particularly in the instance of zinc.

Scrap is not going to be stockpiled under present considerations—not even three-way alloy scrap which under current price policies will find little demand in peacetime steel chemistries.

One year's requirements of such critical metals is the most frequently mentioned supply to be maintained by the services.

Obsolete equipment—The Army has no intention to stock indefinitely weapons of proved obsolescence. Falling into this class would be early tanks and anti-tank guns. Such materiel will, however, be kept as insurance against unforeseen military needs until the progress of the war indicates that it can be safely scrapped.

1943 Finished Steel Production Sets More New Records

Total number of companies included, 184.

During 1942, the companies included above represented 98.8% of the total output of finished rolled products.

* In accordance with Government policy, export figures cannot be published.

Canada's 1943 Ferrous Output Down

Toronto

• • • **Canadian production** of pig iron, steel ingots, and castings, showed declines for 1943, while output of ferro-alloys registered a minor gain, for a new all time record, according to the Dominion Bureau of Statistics. Production for December, was the lowest since January, 1943, when output was sharply reduced by strikes at Algoma Steel Corp., at Sault Ste. Marie, Ont., and Dominion Steel & Coal Corp., Sydney, N. S. Annual production data are shown in accompanying table.

December pig iron production was 137,256 tons, compared with 142,249 tons in November. December ferro-alloy production was 17,038 tons compared with 16,169 tons in November. December production of steel ingots and castings fell to 76.8 per cent of capacity, amounting to 227,822 tons compared with 259,444 tons in November.

It is understood that pig iron soon will be dropped from regulation by the Steel Controller. Other steel materials may soon receive like treatment. Recently the Steel Controller surrendered control jurisdiction over a number of the heavier steel materials, and with surplus stocks or capacity available in Canada most other items may be dropped from regulation control. At the present time sheets appear to be the only scarce commodity in the steel group and delivery against new orders extends four to six months into the future with no surplus capacity available for upwards of four months. On plate and alloy bars some Canadian producers have obtained substantial contracts from the United States and Mexico.

Administration of Canada's cargo ship construction program and the naval shipbuilding activities of the Department of Munitions and Supplies has been merged under the new capital shipbuilding branch with D. W. Ambridge, director-general, C. D. Howe, minister, announced.

Recession in the steel industry has cut some 10 per cent from Canada's capacity output of last year, as well as virtually eliminating import of steel from the United States, but the reduction will not go much farther unless a major and unexpected change occurs in the war situation, according to the Ottawa correspondent of *The Financial Post*. Biggest single cut has been in the shipbuilding program, reflected very sharply in steel requirements. Imports of American steel plate, shapes and bars for shipbuilding, which formerly ran to 500,000 tons a year, have been dropped entirely. In addition, Canadian output of these steel products is off about 14,000 tons a month.

Canadian contracts for steel plate dropped, by the end of 1943, by a total of 30,000 tons a quarter. The Steel Co. of Canada, originally scheduled to provide 30,000 tons of plate in the last three months of 1943, was called upon for only 11,000 tons in that period. Dominion Steel Corp.'s 18,000-ton order was cut in half. Dominion Foundries & Steel's quota was cut to 900 tons instead of the 3000 originally ordered.

Bars and shapes have a similar record. Algoma Steel had been asked for 4500 tons; actually only 10 per cent of the order was wanted.

CANADIAN FERROUS PRODUCTION

	Pig Iron, Net Tons	Ferro-Alloys Net Tons	Steel Ingots & Castings, Net Tons
1943	1,758,265*	218,687	2,996,978**
1942	1,975,015	213,636	3,121,361
1941	1,528,053	213,219	2,701,313

* Includes: 1,456,444 tons basic iron; 148,654 tons of foundry iron; 153,067 tons of malleable iron.
** Includes: 2,841,780 tons of ingots and 155,198 tons of castings.

CMP Developments

• **Dir. 16 to Reg. 1, as amended, makes rules governing replacement of stainless steel rejected by a customer for non-conformity with specifications or for other defects identical with those rules governing replacement of other types of steel. (Release No. WPB-4914.)**

•

• **Reg. 1 has been amended to incorporate all since issued interpretations and to include in the regulation a more flexible provision on returned allotments.**

•

• **Dir. 6 to Reg. 3 defines method of applying split ratings to different production programs. (WPB-4909.)**

Priority Changes

L-30-d—Dir. 1 grants authorization to six manufacturers to produce up to a total of 400,000 pressure canners before July 1, provided that there be no interference with munitions manufacture. (1-31-44)

L-88—Amended order relieves railroads of paper work in connection with obtaining used rails for replacement on the ties. (2-4-44)

L-197—Upon appeal, permits will be granted to the paint, varnish and lacquer industry to procure 5-gal. steel pails for civilian use under certain conditions. (2-5-44)

L-211—Sched. 15, as amended, makes several changes in specifications controlling hot-rolled carbon steel bars. (2-3-44)

L-215—Amended order lifts restrictions on some leather working machinery. (2-5-44)

L-216—Sched. V, as amended, modifies its limitations on the production of files. (2-3-44)

M-9—Amended order eases the controls over movement of copper. (2-1-44)

M-21-a—Dir. 1 has been revoked, but deliveries of rejected corrosion and heat resistant alloy steels, to which it applied, remain subject to all other applicable WPB regulations and orders. (2-1-44)

M-21-d—Revoked order removes restrictions on the utilization of steel mill production facilities for the fabrication of corrosion and heat-resistant chrome steel and on the use of ferro-alloys. (2-2-44)

M-65—Amended order corrects an error which appeared in the original print. It now provides that no person may use in any fashion any cadmium after Jan. 22, for the manufacture of a lead base alloy containing no more than 3 per cent by weight of cadmium for the coating of copper wire. (1-31-44)

M-78—Order revoked thereby removing all restrictions on mercury covered by the order. (2-2-44)

M-126—Amdt. 3 permits limited use of iron and steel in manufacture of specified civilian items. (1-31-44)

M-293—Amended Table 11 puts marine diesel engines under closer control by designating them as "Class Y" products. (1-21-44)

M-293—Dir. 1 to Table 14 makes restrictions on production of boilers for stock applicable to the types subject to the scheduling jurisdiction of the Plumbing and Heating Division. (2-1-44)

M-311—Amended order attempts to accelerate the movement of automotive scrap to the steel mills and at the same time to increase the quantity of used automotive parts required to maintain the nation's automotive transportation. (2-1-44)

Dir. 6 to Reg. 3 rules that when two or more preference ratings (split ratings) are assigned to the same production schedule, they must be split proportionately in applying them to each class of production material required. (2-2-44)

Fire Destroys Republic Pipe and Pickling Plant

Youngstown

• • • **Fire destroyed** the three-story pipe and pickling plant of Republic Steel Corp. in Youngstown last Sunday. The origin of the fire and financial loss were undetermined but its effect on steel production was minimized by company spokesmen. The plant has only been operating on a one shift basis.

Price Briefs

• **Amdt. 88 to RSR 14 provides a special price of $80 per ton f.o.b. producing point, in carload lots of 100 lb. drums for calcium carbide sold for export.**

•

• **Amdt. 14 to MPR 134 makes two principal changes in the regulation establishing rental charges for dump trucks used in construction or road maintenance work. (Release No. OPA-T-1692.)**

•

• **Order 149 to MPR 136 provides for pricing method on used construction machinery when making delivery to the U. S. Army Corps of Engineers, for overseas use.**

•

• **Amdt. 107 to MPR 136 adds scaffolds and masonry saws to the list of articles covered by the regulation establishing maximum prices of machines, parts and machinery services. (Release No. OPA-T-1716.)**

WLB Won't Consider Steel Issues Not Affecting Stabilization Program

Washington

• • • At a hearing called by Phil Murray, the War Labor Board met on Monday, with some 300 steel industry representatives to give colorful fanfare to the last rites of the "Little Steel" formula.

Companies were formally notified by WLB chairman William H. Davis to come to Washington to arrive at "issues and procedures" in connection with CIO's 22 demands. The 300 industry men paid an estimated $100 each to attend, counting railroad fare, hotel bills, and incidentals, to tell WLB what it already knew. They found out that CIO has 600 companies on its preferred list, but that those not in the "basic" steel industry, whatever that is, would not be operated upon by "Dr." Davis at this time. "Basic steel" industry is really the board's lingo for the production and sale of steel.

No procedures were settled upon except that "Dr." Davis made it clear that while the new panel, which was then unpacked, would consider the 17c. an hour demand, collateral wage matters such as vacations and sick leave, but would refer back to "collective bargaining" those issues not affecting the "stabilization program." This was in keeping with Mr. Murray's thinking. Steel men had foolishly thought that these points could be held in abeyance pending the outcome of the wage demands, as a sort of dessert. But, no, the panel will take care of that and it was clear that the no-pay matters will become appetizers.

Mr. Murray, always sartorially resplendent, gave the audience of some 500 persons assembled in labor's borrowed palace in the Inter-State Commerce Building a treat of Scotch inflected bandinage with John Stephens, industrial relations adviser for the United States Steel Corp. Mr. Stephens' cultured voice rang in the gold-decked marble halls, giving back retort for retort.

Steel representatives were regaled with the reasons Mr. Murray gave against holding the panel hearings in Pittsburgh and the lovely names he applied to steel men. Murray let it be known that breaking the government stabilization program was a deed that the whole nation should witness from the vantage point of the capitol. He good humoredly described steel men as "representatives of those powerful interests," and wryly as "agents" of the companies.

Ohio-Michigan Toolmaker's Strike

Cleveland

• • • **The National Administrative** Council of the Mechanics Educational Society of America, meeting at Cleveland on Feb. 7, called off "temporarily a four-day-old strike of 25,000 tool and die makers in some 44 plants mainly in Cleveland, Toledo and Detroit. The National War Labor Board had called a meeting for Feb. 8 and ordered union officials to be present. The union threatened to strike again if the WLB decision is unsatisfactory, but observers feel that the strike is over since the union has made its gesture.

The strike dates back some four months and involves the fact that the UWA-CIO at Willys-Overland plants in Toledo had 9000 members to M.E.S.A.'s 1000, and a pending plant-wide election would put the UAW in full power. The M.E.S.A. did not want the National Labor Relations Board to grant the election on a plant-wide basis. The strike call was made to force NLRB to abandon such plans.

Subpoenas were served by the War Labor Board on the union's top ranking officers, President George White and Secretary Matthew Smith, to appear before the WLB in Washington on Tuesday afternoon. A meeting was called for Monday, but Smith claimed he wouldn't appear. WLB threatened to seek Federal court orders to enforce the union officials to appear if the new subpoenas were disregarded.

U. S. Steel's Production Records

Gary, Ind.

• • • **The Gary works** of Carnegie-Illinois Steel Corp., world's largest steel mill, set a new world's record for steel production, and established five other records. The Gary plant's new mark included production of ingot tonnage exceeding an average of 16,400 net tons daily during January, representing an increase of 9000 tons over the best previous record, established in May, 1942. The new world's record for steel production was reached, officials said, despite an acute manpower shortage which compelled many men to work double time daily on occasions in various plant departments during January.

The other January records included new highs for coke plant and blast furnace production as well as in rolling and plate mills.

Joliet plant operations of the American Steel & Wire Co., established 77 new production records in 1943. The company in 1943 set 912 new production records making a total of 1854 new highs established by this U. S. Steel unit since Pearl Harbor.

The Waukegan plant set 22 new records last year, while Worcester, Mass., operations exceeded previous highs no less than 293 times. The Donora, Pa., plants established 165 new records while the facilities in Cleveland, broke 137 former records. Duluth, Minn., plants entered 81 new records on the books. The New Haven, Conn., plant established 60 records, while Trenton, N. J., exceeded old marks 51 times during the year. The Rankin, Pa., operations with 24 new highs, and the Allentown, Pa., works with two records smashed, complete the list of plants producing for victory.

1944 Ore Quota Set

• • • The WPB Iron and Steel Advisory Committee set a quota of 90,000,000 gross tons of iron ore from the Lake Superior region for 1944. The committee requested that the ODT relax or eliminate restrictions on Lake movement of coal so as to permit a free flow of this important commodity at the same time it announced the new ore goal. The scarcity of manpower, it was pointed out, might require drastic steps in order to put all iron ore and coal boats into service at the opening of the lake season. It is now hoped that shipping will start, at least in the lower lake regions, sometime during March. An early opening of upper lake regions would enhance the chances of moving the required amount of ore to Lake Erie and Chicago docks.

Senate Bill to Supersede Baruch Contract Termination Clause if Passed

Washington

• • • **The Murray** (Senate) Termination bill, sometimes referred to as the omnibus bill, was introduced this week and before the Senate gets through, it may incorporate the Hill (House) Property Management bill reported on Jan. 24. The property disposal provisions of the Murray bill were deleted before introduction.

Briefly, the Murray bill establishes an Office of Contract Termination Settlement with a director empowered to establish policies and regulations to govern the executive agencies in making contract termination settlements.

The legislation was drafted and introduced against the wishes of the White House and the War and Navy Departments. If passed by Congress and signed by the President, the law would supersede the Baruch Contract Termination clause.

The General Accounting Office is given authority to examine settlements but cannot raise debts in the accounts of disbursing or contracting officers who are exempted from personal liability in making settlements. GAO is reduced to making representations to the departments, or reporting to Congress.

Under the bill, procurement agencies, including RFC and SWC can make partial payments up to 90 per cent of a contractor's termination claim, and to make or guarantee loans. The Contract Termination Settlement Director is granted authority to make the regulations governing such payments. If any overpayment is made, it is treated as a loan, repayable to the government on demand with interest at 12 per cent.

The bill provides for direct settlement of suppliers wherever the CTS Director finds it necessary and enables the contracting agencies to purchase the claims of suppliers. The CTS Director is given absolute authority to vary the standards, terms and condition, including the evidence necessary to secure a claim paid by a prime contractor to a supplier.

Moreover the bill permits contracting agencies to award additional payments to suppliers who are deprived of "fair compensation for the termination of a subcontract" on account of the "insolvency, bankruptcy or default" of a prime contractor.

Appeals may be made to the Court of Claims, but terminating agreements are to be final, except (1) to the extent otherwise provided by the terms of the settlement, (2) upon a showing of fraud or malfeasance, or (3) upon renegotiation under the Renegotiation Act unless exempt.

Concerned over the lack of a real government-wide adequate property accounting, the Hill Property Management bill reposes in the Bureau of the Budget authority to collect information secured by the other departments so that appropriation bills can be written on a more factual basis.

Accordingly, the Senate Committee on Expenditures in its report on the bill says that the Bureau of the Budget is now engaged in reviewing agency inventory and property control systems with the view of improvement and establishment of uniform practices.

In general, agencies are given authority to dispose of personal property under present statutes. In the opinion of legislative experts, all the new bill would do is to authorize by a joint congressional committee, and an over-all policy board comprising "five top flight executives from the executive branch, and one representative each of labor, agriculture and industry."

January Ingot Output Totals 7,595,202 Tons

Production of Open Hearth, Bessemer and Electric Steel Ingots, and Steel for Castings. Source: American Iron & Steel Institute

Based on Reports by Companies which in 1942 made 98.3% of the Open Hearth, 100% of the Bessemer and 87.6% of the Electric Ingot and Steel for Castings Production

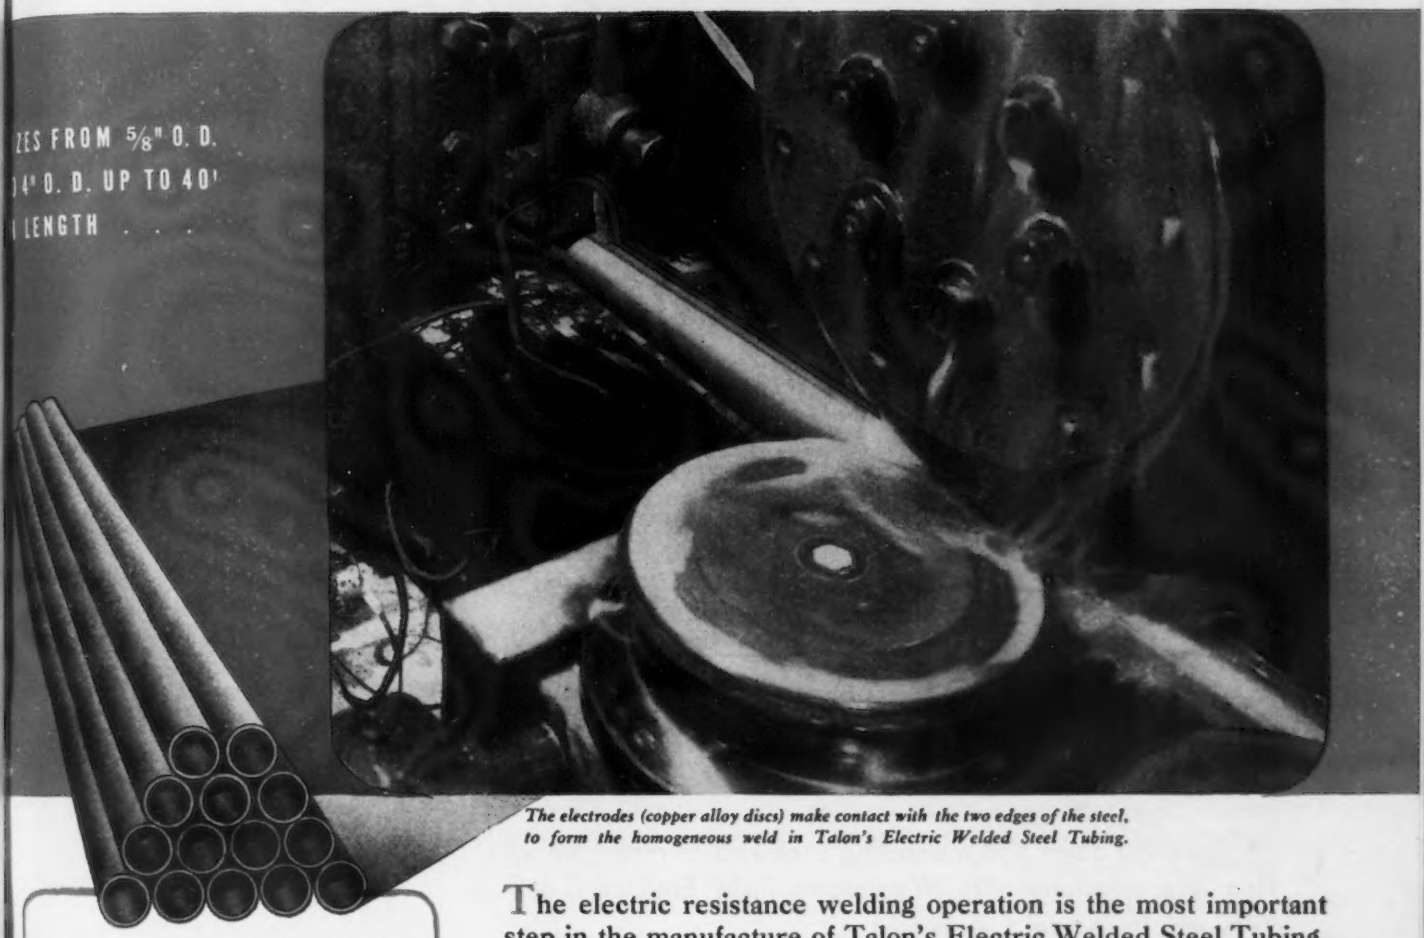
Note—The percentages of capacity operated are calculated on weekly capacities of 1,518,621 net tons open hearth, 125,681 net tons Bessemer and 87,360 net tons electric ingots and steel for castings, total 1,731,662 net tons; based on annual capacities as of January 1, 1943 as follows: Open hearth 79,180,880 net tons, Bessemer 6,553,000 net tons, electric 4,554,980 net tons. Beginning July 1, 1943, the percentages of capacity operated are calculated on weekly capacities of 1,531,789 net tons open hearth, 116,494 net tons Bessemer and 94,667 net tons electric ingots and steel for castings, total 1,742,950 net tons; based on annual capacities as follows: Open hearth 79,867,450 net tons, Bessemer 6,074,000 net tons, Electric 4,935,960 net tons.

* Revised to include production of new facilities not previously reported.

And Now I Pronounce You

TALON'S ELECTRIC WELDED STEEL TUBING



The electrodes (copper alloy discs) make contact with the two edges of the steel, to form the homogeneous weld in Talon's Electric Welded Steel Tubing.

Interesting Facts About Joining Talon's Electric Welded Steel Tubing

Joining Talon's Tubing offers no drawback because almost any conventional method can be used, such as the following:

MECHANICAL METHODS—*threaded joints, riveted joints, drive screws, tapped plugs, and screws, slot and plate, friction clutch, telescoped joints, and patented rivets, screws and bolts.*

WELDING METHODS—*Oxy-acetylene welding, arc welding, atomic hydrogen arc welding, brazing, soldering, and electric resistance welding of various types.*

The electric resistance welding operation is the most important step in the manufacture of Talon's Electric Welded Steel Tubing.

As the tubing moves into position, the welding unit automatically adjusts itself up or down as necessary, and the proper amount of current is introduced. Side roll pressure brings the heated edges together at the instant the current takes hold to form a solid, welded joint. The planer, at the left in the photograph, removes the flash (excess metal) left by the welding operation.

No extra metal is added and the weld becomes a complete union, as strong as the edges and with the same strength and physical characteristics as the steel from which it is made. Subsequent heat treating gives a uniform, homogeneous structure in the weld.

WPB Explains Split Rating Ordering

Washington

• • • **The WPB** announced that when two or more preference ratings (split ratings) are assigned to the same production schedule, they must be split proportionately in applying them to each class of production material required. This application, according to direction 6 to priorities regulation 3, is on a class of item-basis, and must be followed in all instances where more than one preference rating is assigned to one production schedule.

WPB has fixed a base rating which it will assign for ordering production materials that go into each finished product group. The same base rating will be assigned, therefore, to each production schedule covering the same product group. However, higher ratings may be assigned to a portion of the production schedule by WPB.

To illustrate, if it is decided that $100,000 worth of nuts and bolts and $50,000 worth of wiring devices are to be put into production during a quarter and the preference ratings assigned to the schedule are 60 per cent AA-2 and 40 per cent AA-3, the AA-2 rating may be used to buy $60,000 worth of nuts and bolts and $30,000 worth of wiring devices and the AA-3 rating may be used to buy $40,000 worth of nuts and bolts and $20,000 worth of wiring devices.

Steel Bar Controls Changed

Washington

• • • **Several changes** in specifications controlling hot-rolled carbon steel bars were announced by WPB. These changes were made effective by amending schedule 15 of order L-211 and interpretation 1 of L-211.

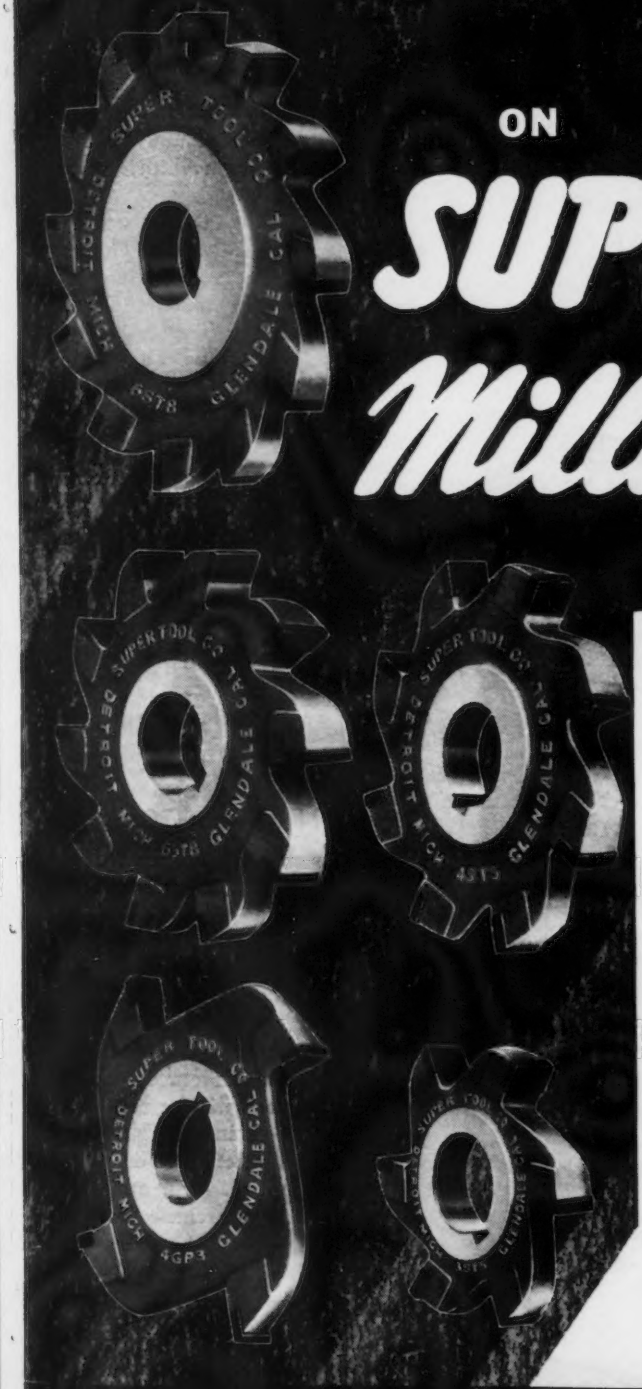
The amendment gives persons engaged in cold drawing carbon steel bars the opportunity to order products best adapted to their future processing operation. Several sizes of bars are eliminated from the table of permitted sizes and two new thicknesses are permitted in the largest size of equal tees.

Orders calling for narrower tolerances than the standard cannot be honored, the amended interpretation points out. The effect on these changes on manpower, materials, and production will be negligible, the WPB said, since they are all purely technical.

PRICES DOWN 25%

ON

SUPER CARBOLOY TIPPED Milling Cutters!



Here's money-saving news for production men! A 25% price reduction on Super Carboloy Tipped Standard Milling Cutters! Think of it! Now you can get the speed, accuracy and dependability of these high quality cutters at prices that mean *extra* economy on all types of production jobs . . . . long runs, short runs, even general shop tooling.

How is this price reduction possible? You'll find the answer in our plants—engineering research and development, improved manufacturing techniques, increased production. And we are passing these savings along to you.

If you haven't yet tried Super Carboloy Tipped Milling Cutters, now is the time to do it! You'll learn first-hand why production men the country over who are interested in stepping up production and stepping down costs, specify SUPER. Write TODAY for complete details as to descriptions, sizes and new low prices.

M-21-d Revoked But Other Orders Control Alloy Use

Washington

• • • **Removal of** restrictions on the utilization of steel mill production facilities for the fabrication of corrosion-and-heat-resistant chrome steel and on the use of ferro-alloys was announced by WPB. At the same time, the WPB "unfroze" stainless steels held by producers and consumers. This action will have no effect, however, upon new production and little effect on use of existing inventories, according to WPB.

The specific step taken is the revocation of order M-21-d. This order was issued when facilities and ferro-alloys were scarce and many controls had to be set up to assure maximum supplies of metals for the war program and to recover the alloys contained in such steels for remelt.

Since the issuance of M-21-d, other close controls on the use of ferro-alloys have been instituted through L orders and CMP, and plans for remelting stainless steels held in consumers' inventories have been dropped.

The WPB said that few appeals have been made and that the revocation of this order will not affect the war production program, since fabrication of civilian items remains under strict control.

Grader Needs Up 30%

• • • **Total** 1944 requirements for motor graders are 30 per cent higher than the entire 1943 output, which amounted to 3607 units, the WPB reported to members of the Motor Grader Manufacturers Industry Advisory Committee.

Pending a determination of how many can be manufactured this year, no motor graders will be released for non-military use, including both governmental and other civilian uses, until further notice. All applications for non-military purchase orders are being denied, except those in the first quarter of 1944 already processed.

Silver Coated Beryllium-Copper

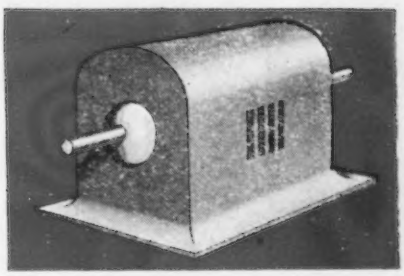
Paterson, N. J.

• • • **By a new** process developed by Little Falls Alloy, Inc., spring grade beryllium-copper wire is being silver coated. This coating is said to reduce wear on wire coiling tools, increase surface electrical conductivity, and reduce surface attack during heat treating and hardening.

PARTS FOR FACTORY EQUIPMENT & MACHINERY

Advances in engineering and design and improved materials will make "The work shop of the world" a new vision of utilitarian beauty.

Pressed Metal Parts and stampings will be used for factory equipment and machinery in the future, just as they have been in the past, but to an accelerated degree. They will make possible revolutionary advances, due to their ability to stand up to abuse, resistance to shock, rugged strength, ability to withstand corrosive conditions, survive radical temperature changes, not to mention low cost and a score of other characteristics, providing requirements not met by any other material.



Sound safe designs literally demand fullest possible use of stampings. Call on the Parish Pressed Steel Company for engineering cooperation. Our services will be found helpful.

Capitalize on R-S

A TYPICAL example of R-S thoroughness in adapting a type of furnace to a particular heat-treating job is the continuous convection, gas-fired furnace illustrated above. Frankly, we are not permitted to divulge full details. Suffice it to say that the production results substantiate our claims of exceptionally uniform and close temperature control (400 to 1300°F.), general over-all efficiency, automatic operation and minimum labor to load and unload. Parts are loaded on the wire mesh belt which moves at a constant, set speed, variable at will.

From the viewpoints of delivery, efficiency in operation and reliability, the R-S Furnace record is truly outstanding. It justifies the use of the expression "Furnaces of Distinction."

Army Axles Exempted From Price Ceilings

Washington

• • • **Exemptions from** price control of the sale and delivery of truck axles by Timken-Detroit Axle Co. to the War Department were announced Jan. 28 by OPA. The exemption applies to axles required for the War Department's truck production program which are the subject of a contract recently negotiated between the War Department and Timken. The actual manufacture will be performed by sub-contractors, with Timken providing engineering direction and knowledge and production supervision, enabling inexperienced sub-contractors to produce the axles. Such an arrangement has been made necessary because of the absence of other facilities for supplying the vitally needed parts.

The Army contract calls for the determination of a firm price after a trial production period, which will enable both Timken and the War Department to determine actual production costs.

In exempting the contract from price control, OPA stated that, in view of the special circumstances of the case as presented by the War Department in requesting OPA action, refusal to exempt the contract would have interfered with necessary war production. The contract with Timken has been drawn so as to avoid inflationary results and the War Department has negotiated the most favorable basis for fixing the final price under the contract that it believes to be possible to obtain under all the circumstances.

WPB Relaxes M-126

Washington

• • • **Even though the** revocation of Order M-126 would not allow new manufacture of 400 classifications of metal articles, according to WPB, the Board decided to relax the order about one eye-dropper full on Jan. 29.

Consequently, the fact that iron and steel may be used for the manufacture of automotive heaters, grease guns and pumps, hose reels and oil pumps, cigarette lighters, motion picture projectors, motion picture sound producing equipment, window shade rollers and stencils, there is no assurance any of these permitted articles will appear on the market in the near future. WPB admits it's "problematical."

FROM AN ORIGINAL DRAWING AND SKETCHES BY ORISON MACPHERSON

EEL FOR WAR

OLD KING COAL

Bituminous coal used for coke making was laid down in form of peat between 200 and 300 million years ago. During this period whole eastern and central part of United States appears to have been in critical adjustment to sea level, now above and now below.

Great push on earth's crust which caused it to fold upwards like pushing together a giant rug, ended more than million years ago and required 60 million years to complete.

Distance Philadelphia to Pittsburgh was shortened by 100 miles during the great up-folding which gave Pennsylvania low volatile coal around Johnstown, medium volatile coal near Indiana, Pa. and high volatile in the vicinity of Pittsburgh.

Mountains 40,000 feet high would have existed in Appalachians if tops of geological foldings had not been eroding away all during the 60 million years uplift.

Ohio River once flowed North up the Beaver Valley and out Grand River into Lake Erie. Course was changed during Glacial Period.

Great Fushun Seam of coal in Northern China varies from 78 to 420 feet thick.

Donbas Basin in Donets Valley, Russia, has 15 seams of coal. Retreating Germans destroyed 140 mines in basin, Russians say.

King Coal's face is washed every day at J&L to prepare him to become better coke when he is roasted in the by-product ovens and converted into fuel for the hungry blast furnaces. Transported direct from the company's mines in river barges, thousands and thousands of tons of coal are daily washed to reduce impurities, such as rock, slate, clay, ash and sulphur, by torrents of water in modern sluice boxes called "launders" which, with vibrating screens, fill the high factory building with loud noise.

The jet black water that has washed the coal is not allowed to run off, but is drained into a pit to precipitate the sediment, which is then dried into dust of coal and blown into steam boiler fireboxes as fuel.

Blending coal, like blending coffees, is done to improve quality. Coals of various types, grades and ages from various mines, or even from the same mine, are carefully, scientifically mixed to insure obtaining coke that is uniform in size, ash and sulphur content.

Coal and Steel: Coal is so essential to steel production that millions and millions of tons of bituminous coal are consumed every year in making steel for war. A ton and seven tenths of coal, converted into coke, is required to smelt the iron ore to make one ton of steel. J&L alone consumes 17 thousand tons of coal every day of the year. Thus, in one day one steel company consumes enough coal to heat 2,500 family dwellings all of a long, hard winter.

Stainless Steel Mill Report Eliminated As Supply Eases

Washington

• • • **WPB on Tuesday** announced that it had relieved stainless steel manufacturers of a reporting procedure set up in times of greater stringency. However, the move represents no real relaxation in controls, officials said. Specifically, Direction 1 to Supplementary Order M-21-a, is revoked, but deliveries of rejected corrosion and heat resistant alloy steels, to which it applied, remain subject to all other applicable WPB regulations and orders.

The directive, issued Oct. 4, 1943, was designed to prevent the intentional classification of stainless steels in producers mills as "off-analysis," in order to obtain approval for their application to comparatively non-essential uses. It also was designed to aid producers in the prompt disposition of steels inadvertently melted off-analysis.

WPB officials explained that reductions in stainless steel production, an easing in the ferro-chromium supply situation, and improved inventory procedures are the chief factors making the revocation possible.

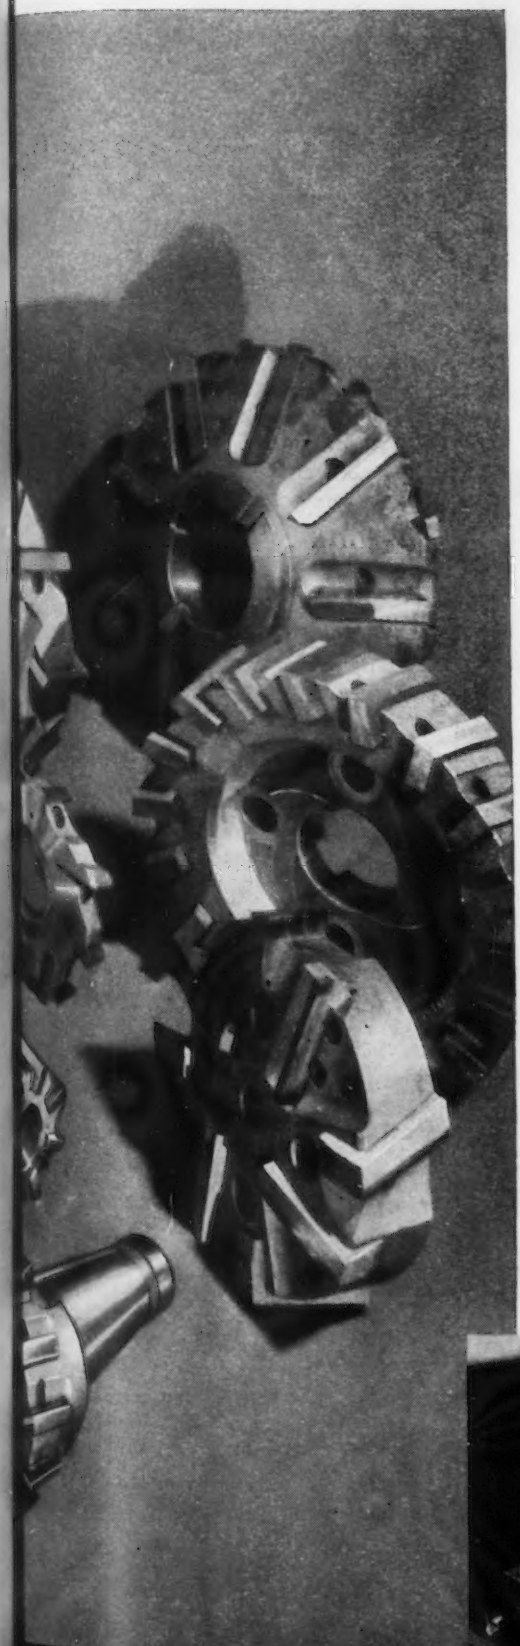
Material Supply List Brought Up to Date by WPB

Washington

• • • **The WPB Conservation** Division has issued its 11th "Material Substitutions and Supply List," which shows an easing of copper and steel. The report emphasizes, however, that "easing" supplies are due rather to the raw materials than to facilities or manpower for fabricating them. This official list carries some 450 materials needed in the war effort, arranged in three groups. Group I shows those whose supply is insufficient for essential needs, Group II those in approximate balance, and Group III those in excess of essential requirements. The total number of materials classified in Group I is slightly smaller than that in October's report.

Tin continues to be short in supply, an exception to the general improvement in the supply of non-ferrous materials. It is recommended that tin be used as little as possible in bronzes and plating. As groups, chemicals and plastics are somewhat tighter than on the previous listings, while textiles and fibres remain about the same. Supply of lumber, in which there is a continued shortage, shows neither improvement nor decline.

AS GOOD AS THEIR CUTTERS



Your machine, regardless of how well designed and equipped in other appointments, gives the best performance only when operated with cutting tools designed for the job.

•

As a natural consequence of meeting and solving many machine problems in milling, Ingersoll has developed a line of milling cutters in types and sizes to suit the conditions of the work. These include cutters for face-milling, end milling, side milling, slotting, channeling, slabbing, form-milling, and many types of boring.

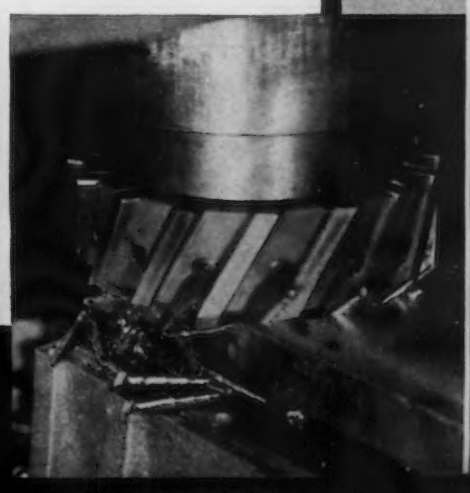
•

If you are not entirely satisfied with the performance of your machines, investigate their tooling. One example of how you may benefit is described at the bottom of this page.

•

In stating the conditions of your work give (1) Kind of material being cut. (2) Width and depth of stock removal. (3) Nature of cut, such as face-milling, slotting, etc. (4) Type of machine drive. (5) And if convenient a sketch of the work-piece.

The same machine was used in both steel milling cuts shown below. The Shear Clear cutter on right, designed for jobs of this type, removed twice the amount of stock in less than half the time. The Shear Clear consumed less power and produced a smoother finish. Are you using the proper cutters in your shop?



ROCKFORD, ILL.

Clean and lubricate your chain!

LENGTHEN ITS LIFE

Here's one good method. Clean your chains regularly. Wipe the links clean, then apply grease or heavy oil mixed with graphite. • Note this exception: Chains should be cleaned but not be lubricated when they come in contact with dirt and sand. • Select good chain (of course we recommend American), care for it regularly, and you'll obtain excellent service. • The highest possible preference rating should be obtained and shown on orders placed for chain.

• USE WELDLESS CHAINS

Weldless Chain is being substituted successfully in many applications, for smaller sizes of welded chain and manila rope. From time to time we have open equipment for manufacturing the following types of weldless chains and attachments: Tenso, Lock-link, Jack, Register, Safety, in steel and brass; American Pattern, in steel; Sash, in steel and bronze. Attachments —"S" hooks, rope snaps, swivel snaps, rings and special designs. Write for information.

Eutectic Welding Alloys Co. Demonstrates Its Processes

New York

• • • **Demonstrations of low temperature** welding techniques were made last week for members of the technical press and the American Welding Society on the occasion of the third anniversary of the formation of the Eutectic Welding Alloys Co., New York. The development of eutectic welding was started in Switzerland in 1906 by Hughes Wasserman, close associate of Dr. Hans Goldsmith, the inventor of the thermit welding process. Low temperature eutectic welding alloys in their present form were perfected by his son, R. D. Wasserman, president of the New York firm.

In these processes, which are similar to brazing, the alloys and base metals develop a strong affinity for one another, even though the melting point of the applied metal is far below that of the parent metal. So-called Autochemic fluxes used with "Eutectic" alloys aid the surface alloying that occurs and increase penetration. That such alloying of diverse metals actually occurs at a temperature below the melting point of either metal was demonstrated by literally pushing an aluminum base rod through a brass plate. Over 40 different alloy rods and fluxes have been developed for joining various metals.

Tests showed that a lap weld made on steel with Eutectic No. 16 rod had a greater strength than the parent material. Another test showed that the Rockwell hardness of deposited Bronzochrom metal could be raised considerably by peening. Such alloys are being used to build up mismachined parts.

Postwar Research Allowed

Washington

• • • **WPB will permit** the use of aluminum for postwar experiments. Heretofore, requests for allocations of the light metal for experiments to work out models for civilian goods after the cessation of hostilities have been refused.

Under the new policy, requests for small amounts of aluminum for experiments will be approved provided experiments can be carried out without diverting manpower, technical skills, or facilities from activities connected with the war effort. The new policy will be carried out within the provisions of order M-1-i, which controls allocation and use of aluminum and aluminum products.

Milestones

• • • **Laclede-Christy Clay Products Co.**, St. Louis, is celebrating the completion of its first century. Started in 1844 as a firebrick manufacturing company, Laclede has since expanded until today its line of products includes almost every phase of the refractory business.

The company pioneered in the manufacture of firebrick by the dry press method, and in the development of alumina refractories through the use of bauxite. It became the world's largest producer of glass-house refractories for the glass industry, when, in 1931, it acquired the entire assets of the Buckeye Clay Pot Co., Toledo.

Cleveland Ordnance District Output Set at $2 Billion

Cleveland

• • • **Col. H. M. Reedall**, district chief, Cleveland Ordnance District, last week stated that more than $2-billion in finished ordnance materiel had been produced by district contractors during 1943. About half of this total, according to Col. Reedall, represents the district's disbursement to prime contractors for finished material while the other half represents the value of material made and inspected here. The approximate $1-billion figure reflects an increase of 55 per cent over 1942 when disbursement was $448,500,000.

In analyzing the contract figures, Col. Reedall said that as of Dec. 31 there were 3021 prime contracts and purchase orders with a value of $2,157,000,000 under administration in the district.

A partial breakdown of the production from the district included: 195,687 military vehicles, 400,000 engines and transmissions, 3864 tanks and tank hulls, 100,000 bullet-sealing gasoline tanks, 2,500,000 tires for military use, 129,526 gun tube forgings, etc., 14,980 carriages, 7,086,842 carbines and related equipment, 471,000 fire control items, 69,000,000 cartridge cases, 28,000,000 shells, 13,000,000 fuses, 5,000,000 shot, 750,000 aerial bombs and hundreds of millions of small ammunition component parts. In finished machinery, 2751 items for Lend-Lease are reported as well as thousands of jigs, fixtures, cutting tools, etc.

Compressor Shutdowns "Get the Air"

SOLNUS OILS

Prevent Carbon and Gum . . . Keep Air Compressor "On the Job"

A steady, dependable supply of compressed air is essential to top-rate production in any machine shop. And reliable compressor performance depends to a great degree on proper lubrication.

Frequent compressor shutdowns were a serious problem to a New Jersey manufacturer of roller bearings. The lubricant being used allowed carbon and gum deposits to accumulate so rapidly on the rings and valves of his compressor that it had to be shut down for cleaning every two or three weeks. The result — less production, lost man-hours, higher costs.

Solnus solved the problem. Today, fifteen months after the former lubricant was replaced by Solnus Oils, not a single shutdown of this compressor due to carbon or gum deposits has been necessary. Thus, once again, Sun has helped eliminate a handicap to vital war production.

You may boost your production by taking advantage of the knowledge and broad experience of a Sun Lubrication Engineer. Let him show you how the right Sun Lubricant in the right place often means higher production, longer machine life, and more profitable operation. Just write to . . .

SINCE 1838
FOR OVER 100 YEARS MANUFACTURERS OF REGULATING CONTROL VALVES AND SPECIALTIES FOR GAS, OIL, STEAM AIR AND WATER

American Foundry Equipment Co.
Mishawaka, Indiana

Attention: Mr. R. E. Schalliol

Gentlemen:

Your 20" x 27" Wheelabrator which was installed and started in operation January 1943, has been an invaluable aid to production of valves for the U. S. Navy and Maritime Commission.

We load all types of bronze valves into the Wheelabrator, usually 150 to 200 lbs. per load. They range from ¼" to 6" in pipe size and from ¼ lb. to 75 lbs. each in weight.

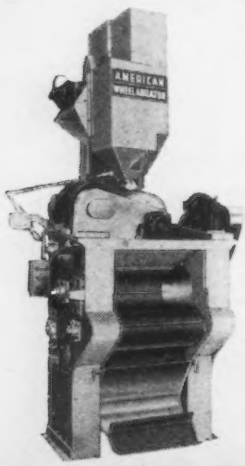
Four minutes per load is sufficient time to clean them and we can turn out about the same amount of work in 2 hours on the Wheelabrator, that formerly required 2 men about 8 hours time on wire brush wheels, and in addition we secure a more uniform appearance on our product.

In view of the difficulty in securing satisfactory foundry help, at present, plus the trouble in getting wire brush wheels, the Wheelabrator has been a life saver in keeping up production.

Very truly yours,
Wm J. Dawer, Foundry Supt.
(Signed) Wm. J. Dawer, Foundry Supt.

final cost ...IS THE PAYOFF ... IN METAL CLEANING

Today the emphasis is on all out production at any cost. Proof that the American Airless Wheelabrator speeds production comes from countless satisfied users like the statement in the letter above, "invaluable aid to production of valves for the U. S. Navy and Maritime Commission."



Tomorrow it will be different! In the post-war world the keynote will be: cost based on efficiency of operation. Proof of the efficiency of Wheelabrator is evident in the above letter as stated, "we can turn out about the same amount of work in 2 hours on the Wheelabrator that formerly required 2 men about 8 hours . . . and in addition we secure a more uniform appearance on our product."

Every day Wheelabrator is giving faster, better production with less cost and a minimum of maintenance. Why not arrange for a demonstration to see for yourself how your products may be cleaned better by Wheelabrating? The world's largest builders of Airless Blast Equipment show record results in final cost . . . and that is the payoff in metal cleaning.

*** Write for further information.**

American
FOUNDRY EQUIPMENT CO.
510 SOUTH BYRKIT STREET • MISHAWAKA, INDIANA

Briefly Told—

• Class I railroads put 28,708 freight cars in 773 locomotives into service during 1943, Association of American Railroads reports. This was the smallest number of cars installed since 1940 but the greatest number of locomotives since 1930. On Jan. 1, 1944, the roads had 35,737 freight cars and 955 locomotives on order, including 339 steam, the electric, and 613 diesel locomotives. ODT reported 33 new locomotives on order on Jan. 1944, by other than Class I carriers.

•

• A new, simplified complete steel price list containing data required to determine or check prices of steel purchased from warehouse stocks, is offered free by the Earle M. Jorgensen Co., steel distributors operating warehouses in Los Angeles and Oakland, Cal., and Houston, Tex. Through the use of this new price list, almost anyone can quickly and accurately establish or check prices of practically all steel items purchased from warehouse stocks because this list contains all data required for this purpose without referring to supplementary extra schedules of any kind. Moreover, whenever extras or deductions are applicable to the pricing of any commodity specific references are made to the tables to be used and the tables show the amount of the extras or deductions.

•

• Colonial Radio Corp., Buffalo, reports production of two-way radios for U. S. aircraft up 400 per cent during the past year while the working force was increased only 50 per cent. President Allen H. Gardner gives much of the credit to the labor-management committee "which has done amazing things in improving worker morale and reducing absenteeism." Sub-contracting also was a factor in the gain.

•

• Rockwood-Sprinkler Co., Worcester, Mass., is turning out large quantities of fire fighting equipment for landing barges. The company's water fog equipment smothers oil fires instantly.

•

• St. Pierre Chain Corp., Worcester, Mass., has a contract for 22,500,000 lb. of anchor chain for the landing craft program. The order represents 325 miles of chain. Work is about to get under way and must be completed in 15 months, according to Henry St. Pierre, president.

•

• The greatest tonnage in history will be carried by Great Lakes freighters through the Soo Locks this year, according to Lieut. Commander Theodore A. Dahlburg, commanding the Coast Guard base at Sault Ste. Marie, Mich. Veteran skippers expressed hopes they would be getting up steam by April 1 but, despite the mild weather, reminded that anything could happen over the lakes in the next two months. The lakes are not iced up very much now, as compared with last year, but there still is plenty of time for deep freezes.

THE SIGN OF THE DODGE TRANSMISSIONEER

WHAT IS TRANSMISSIONEERING?

Transmissioneering is a Dodge engineering technique starting with a study of practical production engineering requirements and resulting in "The Right Drive for Every Job." It is the connecting link between power source and production machine.

Transmissioneering involves the component parts of power drives — bearings — pulleys — sheaves, clutches, etc., each transmissioneered to meet definite service conditions and the assembling of these parts to provide effective drive units.

Dodge transmissioneers in industrial centers provide on the job tranmissioneering and a wide selection of Dodge transmissioneered products available from stock. Call your local Dodge transmissioneer — he will show you how to put *all* your power in the job.

N MAKING A BOLT IN ONE ECOND..AS WE DO IT HERE AT LAMSON & SESSIONS . . .

• To make 100,000 ⅝" x 2" hexagon head bolts from bar stock we start with 48,700 lbs. of raw material. When we have produced 100,000 bolts, they weigh but 24,300 lbs. Our scrap loss is nearly 12½ tons of raw material or about 50%.

To make this hexagon head bolt from round wire on bolt-making machinery we start with 26,100 lbs. of raw material. When we have produced 100,000 bolts they also weigh but 24,300 lbs. Hardly 5% of material used becomes scrap!

The difference between the weight of raw material required for manufacture from hexagon bar stock and the weight of raw material required for manufacture from round wire is 22,600 lbs.—which is the amount of critical raw materials the bolt manufacturer avoided (1) buying, (2) stocking, (3) consuming, (4) converting to scrap, and (5) causing to be re-melted and re-fabricated!

It is important to realize that bolt manufacturers can make bolts by the upsetting or cold forging method from round wire up to ⅞-inch diameter, if they have the necessary equipment as does Lamson & Sessions.

If you need only a dozen bolts of a certain size or type you can afford to make them by milling from the hexagon bar—unless they are "standard" bolts of a size stocked by your jobber.

If you need (or think you need) a "special" bolt—before you make it yourself—find out if you really need the special design or size, or if you can adapt *your assembly design* to use existing "standard" bolt types and dimensions and materials—to save time and get as good a product. In most instances—we've found that you can!

If the information we offer you in our Lamson Blue Book, our standard catalog, isn't sufficient to answer your questions—write us or ask a representative to call before you decide upon a *special* bolt that would require *special* dies, *special* production methods and *special* inspections at every step in its manufacture. If you can use a "standard" product made from existing dies on bolt-making machinery, you have obtained the utmost efficiency—*and you've really "standardized."* Make it a rule for the duration—use a "standard" bolt whenever you possibly can.

THE LAMSON & SESSIONS COMPANY, General Offices, Cleveland, O.

"BOLTS ARE IMPORTANT!"—24-page booklet of currently useful information for buyers of headed and threaded products, and describing Lamson & Sessions' specialty fastenings which have wide industrial applications—*now, and in the post-war period.*

"THE LAMSON BLUE BOOK"—is our standard Catalog of standard products excepting our Aircraft products.

"BOLTS, NUTS & SCREWS"—70 pages of technical and practical information. First copy gratis, requested on your letterhead. Additional copies one dollar each.

"SIMPLIFIED STOCK LIST"—Of bolts, nuts and screws, conforming to latest revisions of the Office of Price Administration, and of great value in showing you in what ratio quantities of various standard products are kept in stock for deliveries, by your jobbers and in our own (and other bolt manufacturers') warehouse stocks.

SPOT-WELDING OF ALUMINIZED STEEL

expedited with

safe, fast-working

OAKITE DEGREASING MATERIALS

Proper surface preparation is recognized today as one of the FIRST essentials in spot-welding aluminum-clad steel sheets successfully. ALL oil, grease, stamping and drawing compound, identification paint, oxide film and discoloration must be THOROUGHLY removed. Surfaces must be put in CHEMICALLY CLEAN, bright condition to reduce flashing and improve consistency.

But how are you going to meet these requirements easily? Many aircraft plants can give you the RIGHT ANSWER . . . and that is to use specially designed Oakite cleaning materials. You, too, will find they speedily and thoroughly remove all foreign matter . . . consistently produce low surface resistance that enables machine operators to make stronger, MORE UNIFORM welds . . . and turn them out on a FASTER schedule!

Technical Bulletin *FREE!*

Free to production and engineering executives, a 13-page technical bulletin completely describes the Oakite Surface Preparation Process for aluminized steel as well as for aluminum and aluminum alloys. Write for YOUR copy today!

(26) 1,714,445. Soldering and welding medium for aluminum. W. Reuss, Germany. 3-21-29.

To be Continued in an Early Issue

Contracts Awarded by DPC and War Dept.

• • • **Defense Plant Corp.**, RFC subsidiary, authorized the following contracts:

General Electric Co., Schenectady, N. Y., to provide additional equipment at a plant in Erie, Pa., at a cost in excess of $200,000, making a total commitment of more than $2,000,000.

Lombard Iron Works Co., Augusta, Ga., to provide additional equipment at a plant in Augusta at a cost in excess of $45,000, making a total commitment of more than $265,000.

Gulf Distilling Corp., Gretna, La., to provide additional equipment at a plant in Gretna at a cost in excess of $130,000, making a total commitment of more than $250,000.

Nathan Mfg. Co., New York, to provide equipment at a plant in New York at a cost in excess of $160,000.

James B. Beam Distilling Co., Clermont, Ky., to provide plant facilities in Clermont at a cost in excess of $140,000.

Packard Motor Car Co., Detroit, to provide additional equipment at a plant in Detroit at a cost in excess of $120,000, making a total commitment of more than $2,650,000.

Woodall Industries, Inc., Detroit, to provide additional facilities at plants in Monroe and Detroit at a cost in excess of $170,000, making a total commitment of more than $800,000.

Babcock & Wilcox Tube Co., Beaver Falls, Pa., to provide additional facilities at a plant in Beaver Falls at a cost in excess of $50,000, making a total commitment of more than $145,000.

Keystone Mfg. Co., Boston, to provide equipment at a plant in Boston at a cost in excess of $175,000.

Lock Nut Corp. of America, Chicago, to provide equipment at a plant in Chicago at a cost in excess of $25,000.

Hammer Dry Plate & Film Co., St. Louis, to provide plant facilities in St. Louis at a cost in excess of $450,000.

Pittsburgh Plate Glass Co., Pittsburgh, to provide facilities at a plant in Martinsville, W. Va., at a cost in excess of $420,000.

The Henry & Wright Mfg. Co., Hartford, Conn., to provide additional equipment at a plant in Hartford at a cost in excess of $55,000, making a total commitment of more than $125,000.

The War Department announced:

Brown & Rott, Inc., Houston, Tex., award of contract for construction of firing-in range, runways, taxiways and apron expansion at Matagorda Peninsula, Tex., Bombing Range. Estimated amount of contract is $1,011,404.10. Work will be supervised by the Galveston district office of the Corps of Engineers.

Truck Output Hits 100,000 Mark

South Bend, Ind.

• • • **Studebaker's production** of military trucks has passed the 100,000 mark, indicating that the company is among the largest producers of trucks at this time, surpassed only by one other concern in the manufacture of vehicles above the two-ton classification.

Studebaker's output for war purposes is exclusively in the four and six-wheel drive classification. Output of 100,000 units of the heavy duty cargo carrier type was said to be three times the number built in that category by the entire automotive industry in the peak year of 1941.

Correct working pressure

MEANS BETTER OPERATION OF PNEUMATIC EQUIPMENT

Better control helps operators get more production. Many jobs on arbor presses, riveters, air chucks, cylinders, air vises, and other pneumatic machinery can be handled better at reduced pressure rather than at full line pressure. With a Hannifin piston-type pressure regulator for each machine, the correct and most efficient working pressure is instantly available. The wide range of adjustment makes this valve adapted to many different service needs. Write for Bulletin 56-A.

Machining Plastics

(CONCLUDED FROM PAGE 61)

lubricant, to wash away the grindings and keep the wheels free.

Vulcanized fiber may be sawed, sheared, drilled, tapped, milled, turned, threaded, punched and shaved with ease and it can also be formed in dies much the same as sheet metal is formed.

Molding and Extrusion Processes

Compression molding as generally practiced in the plastics molding industry is an old and apparently very simple process requiring only a heat-reactive molding compound which is placed in the mold, pressure to close the mold and a heat source to heat the mold to a correct temperature, while the pressure is forcing the mold to a closed position.

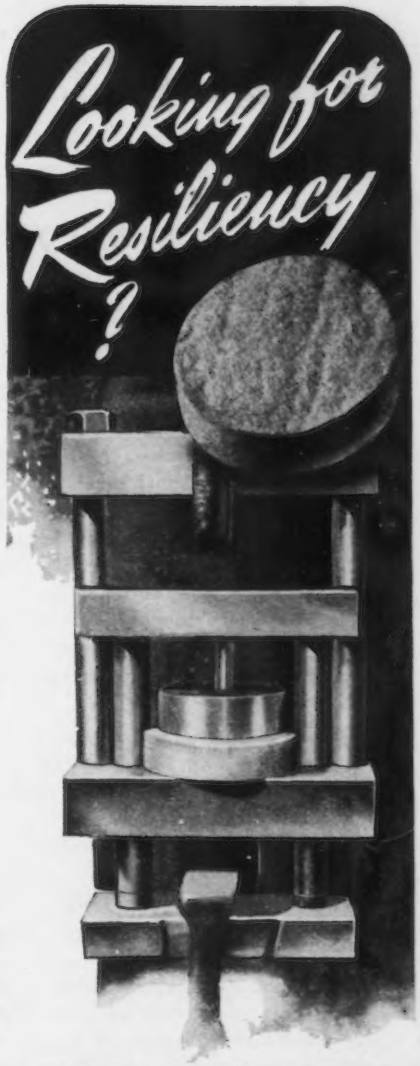
Injection molding consists essentially of transforming granular plastic material into a flowing state by the application of heat, and by forcing it under high pressure (usually averaging 20,000 to 35,000 lb. per sq. in.) into a cold mold where it forms. In actual practice the process is almost entirely automatic and the operator's duties consist mainly of closing the mold by means of electric controls. Ejection of the finished article may or may not be automatic and the material for injection molding can easily be classified as thermoplastic.

Transfer molding is defined as the process whereby a thermosetting material is subjected to heat and pressure, and then forced into a closed mold cavity and cured therein. In other words, it is the injection molding of heat hardening materials and differs from the injection of molding of thermoplastics in that the mold is maintained at elevated temperatures and the parts are ejected from the mold without any cooling. Transfer molding is especially adapted to production of complicated parts for telephone systems, airplane engines, ammunition, block holders and other parts held to extremely close tolerances. Some transfer molds are made of plaster of paris where only a few pieces are made and molds are also made of bronze and steel, however, steel molds are not hardened until it is certain they are dimensionally correct.

Jet molding is a continuous injection molding of thermosetting and thermoplastic materials. In continuous injection molding of thermosetting resins by the jet molding process, all of the heat necessary to polymerize the material to be molded is introduced into the material before it reaches the die. Thus the mold is used only to shape the plastic during the relatively brief setting time that thermosetting materials require, once polymerization is completed.

Continuous dry extrusion as its name indicates is a technique of almost uninterrupted production. The method may be compared to squeezing toothpaste from a tube. The plastic in powder, granular, cube or sheet form is fed constantly into the extruder. As the material is spiralled through a heated cylinder by the action of a mechanical screw, it forms a molten molasses-like mass. Pressure finally forces the plastic through an orifice in the die, and the shape of the die determines the shape of the finished extrusion. As the hot plastic comes from the die, it is cooled by air or liquid and then carried off on a conveyor belt or cutting mechanism.

Continuous wet extrusion is used for the cellulose plastic materials. This process is performed only by a limited number of concerns in the country, principally because the preparation of the raw material is a very important part of the process. The raw materials are placed in a large steel mixer and are thoroughly kneaded into a homogeneous mass and after a definite mixing period (which is determined by the type of material desired) the stock is filtered to remove solid impurities. From there, the stock is either remixed to reclaim the solvents and then put on calendar rolls, or it goes directly to the rolls. The stock is rolled until the necessary amount of solvent has been driven off and the color has become completely and uniformly absorbed. The stock may then be rolled into a thick blanket and then formed in a long cylinder which is known as a jelly roll, or it may be taken off in short strips. Wet extrusion machines are of the hydraulic type known as stuffers or the screw type machines.



IN EXTENSIVE laboratory tests, the compression of certain (½-inch thick) Booth felt samples under load of 150 lbs. per sq. in. resulted (after load removal) in "permanent" loss in thickness of only .005 inch!

Yes, Booth "prescription" felt manufacture can be controlled to give you the amount of resiliency, or almost any other quality, desired in your material.

MACHINE TOOLS

. . . News and Market Activities

Drastic Screening Reduces Order Volume

Cleveland

• • • **The immediate prospects** of the machine tool industry here are varied but on the whole not very optimistic. Orders are continuing to fall off and the outlook at present is that this trend will continue with increasing impetus during the next 60 days. Backlogs are widely varied as between manufacturers, with some still having fairly comfortable volume on hand while others are reaching the bottom of order backlogs. Contract work in machine tool plants is at a satisfactory level.

Special tool orders are helping considerably in filling the gaps for some manufacturers and have been responsible for a portion of the industries present volume although even these orders are reported on the decline in line with the prevailing trend.

It has been particularly noticeable here that the government is screening priorities extremely closely for the purchases of new machines and a considerable pressure is being exerted to force the buying of pool machines rather than new machines from the makers even though in some cases the pool machine is not the most efficient for the job involved.

Certain manufacturers are experiencing a little boom from the return to buying activity of industries that have been heavily restricted until recently. Most notable among these industries has been the oil industry whose current buying is boosting threading and tapping equipment sales temporarily. One threading machine manufacturer is reported turning business away through extended delivery promises caused by the current volume.

National Acme is planning to embark within the next two months upon a tool rebuilding program which will offer users of its machines complete retooling and rebuilding on machines of about the last three models which cover about the last 15 years' production. The unsatisfactory experience of other makers who have engaged in rebuilding programs has not discouraged National Acme and the current plant appears sound.

Rumors brought to town from Washington indicate that foreign buying of machine tools on a cash basis is due to develop within the next few months. The trend appears to be away from Lend-Lease. The British procurement contracts are reported now to be incorporating cash payment. A heavy Russian machine program is believed in the offing and is expected to be on a cash basis.

Cushman Chuck Starts Closing New Plant

Hartford

• • • **Beginning with** the release of 175 employees last week, the Cushman Chuck Co., Hartford, has begun to close down its new plant on Windsor Street, according to an announcement made by George A. Highberg, president. The company's decision to stop production in the new shop was made due to a "business letdown," Mr. Highberg said, and will release between 300 and 400 workers in the next two months. The company will continue to operate its old plant.

Machine Tool Element Standards Approved by ASA

New York

• • • **The American Standards Association** has recently approved two standards in the field of small tools and machine tool elements. The American Standard, Tool Shanks and Tool Posts for Lathes, Planers, Shapers, Boring Mills, and Turret Lathes (B 5.2-1943) covers (a) the cross-sectional dimensions and lengths of flat of shanks of single-point tools, solid or tipped; (b) corresponding tool post openings and recesses for lathes and for planers and shapers, and (c) shank dimensions of tool holders for other lathe tools, such as cut-off tools, and for carbide tipped tool holders.

The second standard approved, Spindle Noses and Arbors for Milling Machines (B 5.18-1943), covers the series of designs and dimensions of the spindle, spindle end and arbors for a line of medium and heavy milling machines previously adopted as a standard by the National Machine Tool Muilders Association. All of the dimensional data are given for sizes 30, 40, 50 and 60, corresponding to gage diameters of the spindle nose taper of 1¼, 1¾, 2¾, and 4¼ in., respectively.

The new standards may be obtained from the American Standards Association, 29 West 39th Street, New York 18. The standard for tool shanks and tool posts is 35c. a copy and the standard for spindle noses & arbors for milling machines is 25c. a copy.

Increase in Layoffs Expected As Orders Decline

Cincinnati

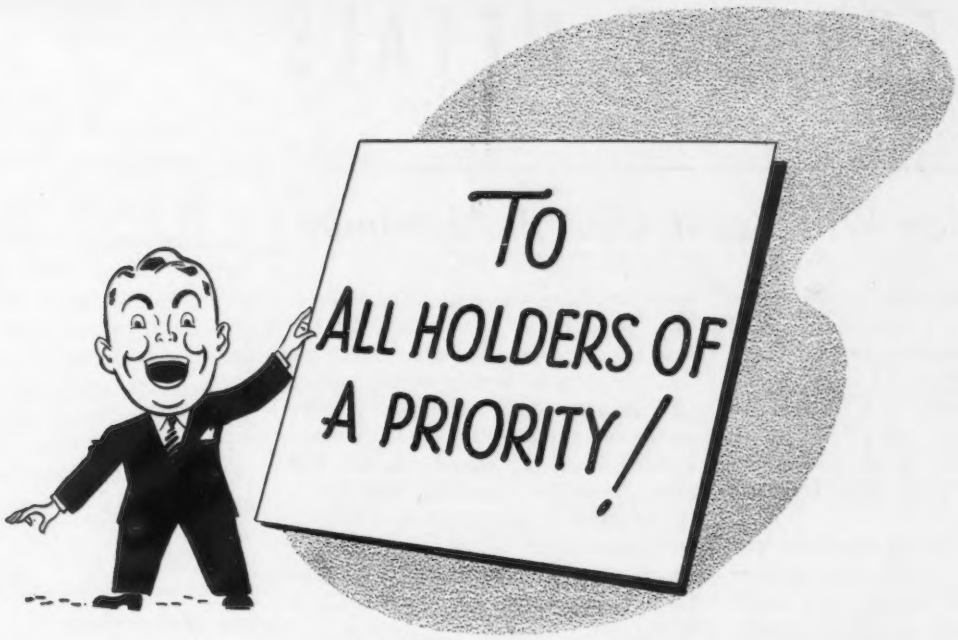
• • • **Most tool plants** in this area are gradually getting down to the bottom of the pile of orders and as the bottom approaches, the problem of continuing to maintain employment forces intact increases. Virtually all plants in the area have some direct war manufacturing or are subcontracting for manufacturers who are in need of machining or still have some parts for machine tools to be manufactured. The release of employees has not been great, since most plants have adopted a very conservative position in regard to replacing men taken in the draft or men who leave the machine tool plants. Despite this, however, there has been some layoffs and some indication of further layoffs is expected, unless extensive amount of new business comes in.

New business has not been disappointing, but is not in sufficient volume to keep operations at the high rate that has been maintained heretofore at the expanded capacity brought about through war increases.

Big Billet Shear Shipped

Buffalo

• • • **Buffalo Forge Co.**, Buffalo, has completed a billet shear for Timken-Detroit Axle Co. that will slice 10-in. round or 9-in. square soft steel billets. The huge machine also will slice 7¼-in. round and 6½-in. square nickel steel billets. The shear, largest of its type ever built, weighs 165,000 lb. and has a knife pressure of 4,500,000 lb. It will make 6 cuts a min. Designed by Gustav H. Zimmer, Buffalo Forge engineer, the shear's main frame is of steel armor plate and its 11½-ft. bull gear has machine-cut teeth. The clutch and holding device are air operated. Power is supplied by a 125-hp. electric motor.

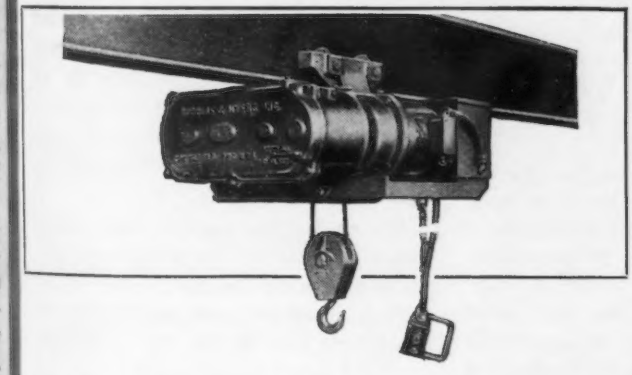


MAKE THE MOST OF YOUR MANPOWER, NOW...

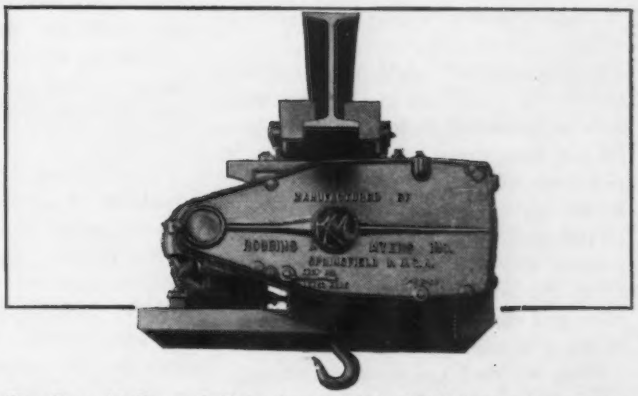
GET R & M HOIST DELIVERY *promptly!*

Eliminating the need for "muscle" on many jobs, R & M Hoists suit today's production requirements. Their simplicity of operation offers increased output ... with less fatigue for inexperienced workers—with greater benefit to management.

In a short time, you can make the most of your manpower. You can move materials faster and easier with fewer men when you use an R & M Hoist. Two of the many hoists available for quick delivery are shown below.



The R & M Type F½ Hoist has 1,000—2,000-pound capacity. It is provided with pendent, push-button control. A step forward in improved design, better materials, and manufacturing economies that provide a better hoist at lower cost in both purchase price and operation.



The R & M Type F Hoist has 1,000—15,000-pound capacity. Push-button control is standard. Operating with low headroom and handling loads from any angle with perfect balance, the Type F Hoist makes a one-man job of many otherwise cumbersome operations.

Begin, today, to enjoy the benefits of simpler, more profitable materials handling

NON-FERROUS METALS

. . . News and Market Activities

Competition Will Boost Use of Aluminum

• • • **Although aluminum production** today is six and a half times what it was in 1939, the postwar demand for the metal will absorb every pound that can be turned out, Walter L. Rice, president of Reynolds Mining Corp., said recently in an address to members of the New York Institute of Finance.

Mr. Rice, who is also vice president of the Reynolds Metals Co., pointed out that WPB still restricts the use of aluminum, although one of its officials recently said that the nation now had so much of this metal that it was "running out of our ears."

Mr. Rice suggested that the statement was only intended to mean that the supply of aluminum was ample for use in the manufacture of airplanes and not that this country had more of it than could be used after the war.

After outlining postwar uses for aluminum in fields other than aviation, Mr. Rice predicted that a million-ton aluminum industry will look small to this country within the next 10 years.

In the postwar world, Mr. Rice said, the use of aluminum in transportation will be increased materially. He pointed out that prior to the war only 29 per cent of aluminum produced had gone into transportation, but predicted that this figure would be increased to between 60 and 70 per cent after the war, when trucks, automobiles and railroad cars would be made, at least in part, of aluminum.

"But whether the production of airplanes declines after the war from 100,000 planes a year to 25,000 or even 5000, it is expected that other transportation facilities will demand the bulk of all the aluminum that can be produced on a competitive basis in this country."

Mr. Rice pointed out that, prior to the war, there was only one producer of aluminum in the United States. For that reason, he said, aluminum was virtually a "luxury metal," which had always sold at a relatively high price compared with steel, copper, zinc, lead and the heavier metals. The prewar low for aluminum was 20c. a lb., he pointed out, but now aluminum and magnesium are the only metals which have decreased in price. The former, he pointed out, sells for 15c. a lb.

Mr. Rice predicted that aluminum would be used in the manufacture of automobile doors, gas tanks, crankcases, gas feed lines, wiring, radiators, generators, lamps distributor housing, valve chamber covers, intake manifolds, fuel pumps, connecting rods, camshaft timing gear and even the chassis.

He said that with the rebirth of the aluminum industry in the last three years, tremendous advances had been made in the purity of the metal and in its treatment. He also pointed out that the unprecedented use of aluminum during this period has educated a new group of technicians in the treatment and application of the metal.

Contrasting the postwar and prewar position of aluminum, Mr. Rice said: "A majority of the manufacturers of automobiles, trucks, refrigerators, radios, railroad cars, household furniture, building material and other durable goods would automatically rule out 20c. aluminum available from a single source of supply, but would feel quite differently about 15c. aluminum available from two or more dependable and competitive sources."

The sudden expansion of the aluminum industry during the last few years may give the industry some growing pains in the months following the armistice. "The government," he said, "may well be expected to protect the industry with respect to large inventories of specially alloyed metal necessary to maintain the flow of sheet, rod, extrusions and forgings to the aircraft plants. Certain stock piling measures may also be in order. But when the period of adjustment is passed, I expect aluminum to play a major role in the new age of light metals."

Corrosion Resistant Film for Magnesium

San Diego, Cal.

• • • **A protective coating** said to make magnesium alloys as noncorrosive and abrasion resistant as aluminum alloys has been developed by engineers of the Consolidated Vultee Aircraft Corp.

This anodic film is described as extremely tight and readily withstands a potential of 110 volts which, together with its resistance to wear and impervious surface, accounts for its ability to retard corrosion.

Convair engineers say accelerated tests show magnesium alloys coated with the new finish holding up as well as, and in some cases, better than anodized duraluminum, and that abrasion resistance is 50 to 100 times superior.

Search for the coating was undertaken in 1941 at Consolidated's San Diego plant but the satisfactory method was developed only recently at the company's Fort Worth, Tex., division.

WPB Thaws Inventories

• • • **Frozen inventories of copper** and copper base alloy pipe, tubing and fittings in the hands of utilities were freed by WPB for use in underground gas and water supply and distribution installations outside buildings.

This action was effected by amending Supplementary Conservation Order M-9-c-4 and was made possible by the better supply-demand situation of copper ingot, which makes purchase of completely fabricated material for remelt no longer necessary. In the past, finished products were remelted to furnish ingots for items more needed in the war effort.

SCRAP

Scrap Shipments From West Coast Cause Conflicting Reports

New York

• • • **Conflicting reports** have been received during the past two weeks concerning the movement of scrap from the west coast to steel mills in the midwestern and eastern areas. First reported from San Francisco was the fact that from 10,000 to 20,000 tons would be moved eastward during February because west coast mills were stocked for at least 90 days. Late in January, this shipyard scrap was selling on the coast at from $1 to $2 below the ceiling, and turnings and borings were going at far below ceiling prices.

Last week shipments of several thousand tons of scrap from the coast were made to a Chicago mill, but because of the easy situation on scrap that has developed in the Chicago area, it was reported that this would likely be the last major remote territory shipment to the area. Plentiful scrap supplies plus an adequate supply of pig iron in the area resulting from full operation of the district's blast furnaces seemed to highlight a ban on such scrap movement for the time being at least.

However, during the past week the Maritime Commission was reported to be shipping about 75,000 tons of producers' scrap to northern Ohio and other points eastward, as well as to Chicago. This scrap is being moved over land grant railroads, with the purpose of draining off excess scrap on the coast. These deliveries are scheduled to continue at least through February.

As has been known for some time, alloy borings and turnings have not been bringing ceiling prices. The stock of such grades has grown to such proportions that dealers and brokers have been unable to handle the large supply and yards as well as mill stocks are reaching the overflowing point. One Cleveland mill has had a railroad embargo placed upon it because of the inability to clear sidings of scrap laden cars. However, turnings from the Cleveland area were finding their way into the Pittsburgh district this past week at ceiling prices. This further indicates that surpluses are accumulating in the Cleveland area and the price must naturally be pretty weak if they can be shipped to Pittsburgh and still be sold at ceiling prices.

WPB Acts to Speed Car Wrecking

Washington

• • • **Because many** vehicles finding their way into auto wreckers' yards have not been promptly dismantled, WPB this past week ordered that such vehicles be dismantled within a reasonable time so that serviceable parts are made available for replacements and scrap metal moves without delay. In June, 1943, WPB prohibited the scrapping of serviceable used automotive parts.

The new order provides that when it is determined by WPB that motor vehicles acquired by an auto wrecker are not being dismantled at a rate sufficient to meet the needs for scrap and serviceable parts, WPB written direction may order any auto wrecker not to purchase or accept delivery of additional motor vehicles until he has dismantled a specified number then in his yard.

A point which has apparently troubled scrap dealers is also clarified. By adding the words "as scrap" to the order, it is made clear that the prohibition against scrapping used parts does not apply when scrap dealers purchase parts "as scrap."

The original order requested purchasers of used parts to turn in parts of similar type and size. As such turn-ins are not always practicable, the amendment to order M-311 does away with this requirement where the part for which the replacement is purchased has been consumed in use, lost or stolen, or when the part is ordered by telephone, telegraph, or mail and is shipped to the purchaser.

•

CINCINNATI—The district scrap market is without noticeable brilliancy. Cast grades and rails for melting are in rather stiff demand, with the supply not too good, although coverage of current needs is reported. Open hearth consumers are apparently in good shape, because of lack of pressure from this source, with some indication that scrap users are cagey and watching inventories carefully. Dealers indicate that movement to yards continue to be in a small amount, but sufficient is moving to take care of current pressing needs.

•

BOSTON—Demand for all kinds of scrap except alloy far exceeds supply. The trade is largely dependent on production scrap, the supply of which is steadily decreasing as more and more plants stop making munitions. Those plants not having war contracts report difficulty in getting operating schedules above 50 per cent of capacity. A majority of yards report a falling off in shipments each month, while the largest brokers say their business is at a record low level.

•

CLEVELAND—The Cleveland market is nearly at a standstill from the standpoint of local deliveries, but a good demand for open hearth grades for Youngstown and vicinity is noted. Turnings are very weak and are further aggravated by the continued railroad embargo of one of the largest local turnings consumers. Light movement of alloys into the Pittsburgh area have been reported with some sales going below the ceiling. Blast furnace demand has been poor. Steel furnace cast is also fading in demand although cupola cast is in heavy demand and poor supply. Requirements, however, are being met. Plentiful supplies of foundry iron are expected to cut cast scrap demand soon.

•

BIRMINGHAM — The railroads have been ordered by the Alabama Public Service Commission to reduce minimums on the intrastate shipment of sheet scrap, 16 gage and lighter, from 50,000 and 80,000 lb. per car to 30,000 lb. for the duration. This order was asked by scrap dealers to facilitate movement of the light material to concentration points where presses are located and where the material can be processed by bailing and made suitable for open hearth furnace use.

•

PITTSBURGH—Prices are firm on all grades, although some exceptionally light low phos plate clippings are probably finding their way into heavy melting steel. In the past two weeks, quality rejections have been heavy, but in the past few days the rejections have had the effect of tightening up grading. Although turnings are being sold here at the OPA ceiling, the fact that they are being imported from long distances would indicate no real strength at the source of supply.

•

ST. LOUIS—Consumption of scrap iron by steel mills in the St. Louis industrial district continues heavier than receipts, one plant using 10,000 tons more than it received in January. Inventories are said to be sufficient for five weeks. Scarcity of scrap and labor to handle it has caused receipts to decline. Most scrap coming in is allocated from remote areas.

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles: No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing points (cents per gross ton) are: Pittsburgh, Brackenridge, 55c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, 42c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Harrisburg, Phoenixville, Bethlehem, Kokomo, Duluth, St. Louis, 28c.; Buffalo, Claymont, 36c.; Conshohocken, 11c.; Atlanta, Birmingham, 32c.; Pittsburg, Cal., 42c.; Middletown, 14c.; Sparrow's Point, 11c.; Chicago, 84c.; Detroit, 53c.; Alabama City, 26c.; Minnequa, 22c.; Seattle, 38c. At Cincinnati, for basic open hearth grades, foundry steel and auto springs and crankshafts, deduct 80c. per ton.

PITTSBURGH basing point includes switching districts of Bessemer, Homestead, Duquesne, Munhall and McKeesport. Cincinnati basing point includes Newport, Ky., switching district. St. Louis includes switching districts of Granite City, East St. Louis, Madison, Ill. San Francisco includes switching districts of S. San Francisco, Niles and Oakmont, Cal. Claymont, Del., includes the switching point of Chester, Pa. Chicago includes Gary, Ind., switching district.

MAXIMUM SHIPPING POINT PRICE—Where shipment is by rail or vessel, or by combination of rail and vessel, the scrap is at its shipping point when placed f.o.b. railroad or f.a.s. vessel. In such cases, the maximum shipping point prices shall be: (a) For shipping points located within a basing point, the price listed in the table above for the scrap at the basing point in which the shipping point is located, minus the lowest established switching charge for scrap within the basing point and (b) for shipping points located outside the basing point, the price in table above at the most favorable basing point minus the lowest transportation charge by rail or water or combination thereof. In lieu of dock charge add 75c. a ton, but 50c. if moved by deck scow or railroad lighter. Shipping by motor vehicle: The scrap is at its shipping point when loaded. For shipping points located within basing points take price listed in table minus applicable switching charge. If located outside a basing point, the price at the most favorable basing point minus lowest established charge for transporting by common carrier. If no established transportation rate exists, the customary costs are deducted. Published dock charges prevail. If unpublished include 75c.; at Memphis, 50c.; Great Lakes ports, $1; New England, $1.25. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding grade or grades of prepared scrap. In no case, however, shall electric furnace and foundry grades be used as the "corresponding grade or grades of prepared scrap." Converter may charge $2.50 per ton on consumer-owned unprepared remote scrap (see order). A preparation-in-transit charge for allocated unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced—$2; 75 to 85% Fe—$4; under 75% Fe—$8 per ton. Mill scale of 65% or more Fe—$8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1 per cent oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5 per cent oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c.

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto, Ohio; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.; Sheffield Steel Corp. $2.55 St. Louis.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo, Colo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—Sheffield Steel Corp. $2.75 St. Louis; W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery in U. S. except Texas and Oklahoma may use Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. when shipped outside Alabama, Mississippi, Louisiana, Georgia, Florida, Tennessee, Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base granted on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base granted on Kokomo, Ind., product; Superior Sheet Steel Co. granted Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1999 lb.; strip, extras on all quantities; bars, 1500 to 39,999 lb.; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 to 39,999 lb. (15) 1000 to 39,999 lb. (16) 1500 to 39,999 lb. (17) 2000 to 39,999 lb. (18) 3500 to 39,999 lb.

(*a*) **Philadelphia:** Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

CAST IRON WATER PIPE

Per Net Ton

6-in. and larger, del'd Chicago	$54.80
6-in. and larger, del'd New York	52.20
6-in. and larger, Birmingham	46.00
6-in. and larger f.o.b. cars, San Francisco or Los Angeles	69.40
6-in. and larger f.o.b. cars, Seattle	71.20

Class "A" and gas pipe, $3 extra; 4-in. pipe is $3 a ton above 6-in. Prices shown are for lots of less than 200 tons. For 200 tons or over, 6-in. and larger is $45 at Birmingham and $53.80 delivered Chicago, $59.40 at San Francisco and Los Angeles, and $70.20 at Seattle. Delivered prices do not reflect new 3 per cent tax on freight rates.

LAKE SUPERIOR ORES

(51.50% *Fe, Natural Content, Delivered Lower Lake Ports**)

Per Gross Ton

Old range, bessemer, 51.50	$4.75
Old range, non-bessemer, 51.50	4.60
Mesaba, bessemer, 51.50	4.60
Mesaba, non-bessemer, 51.50	4.45
High phosphorus, 51.50	4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

PRICES

SEMI-FINISHED STEEL

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Steel

Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton	54.00

Shell Steel

	Per Gross Ton
3 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleveland, Youngstown and Birmingham.

Prices delivered Detroit are $2.00 higher; E. Michigan, $3 higher.

Note: The above base prices apply on lots of 1000 tons of a size and section to which are to be added extras for chemical requirements, cutting, or quantity.

Sheet Bars

Pittsburgh, Chicago, Cleveland, Youngstown, Buffalo, Canton, Sparrows Point, Md.

	Per Gross Ton
Open hearth or bessemer	$34.00

Skelp

Pittsburgh, Chicago, Youngstown, Coatesville, Pa., Sparrows Point, Md.

	Per Lb.
Grooved, universal and sheared	1.90c.

Wire Rods

(No. 5 to 9/32 in.)

	Per Lb.
Pittsburgh, Chicago, Cleveland	2.00c.
Worcester, Mass.	2.10c.
Birmingham	2.00c.
San Francisco	2.50c.
Galveston	2.25c.

9/32 in. to 47/64 in., 0.15c. a lb. higher. Quantity extras apply.

TOOL STEEL

(F.o.b. Pittsburgh, Bethlehem, Syracuse)

	Base per lb.
High speed	67c.
Straight molybdenum	54c.
Tungsten-molybdenum	57½c.
High-carbon-chromium	43c.
Oil hardening	24c.
Special carbon	22c.
Extra carbon	18c.
Regular carbon	14c.

Warehouse prices east of Mississippi are 2c. a lb. higher; west of Mississippi 3c. higher.

CORROSION AND HEAT-RESISTING STEEL

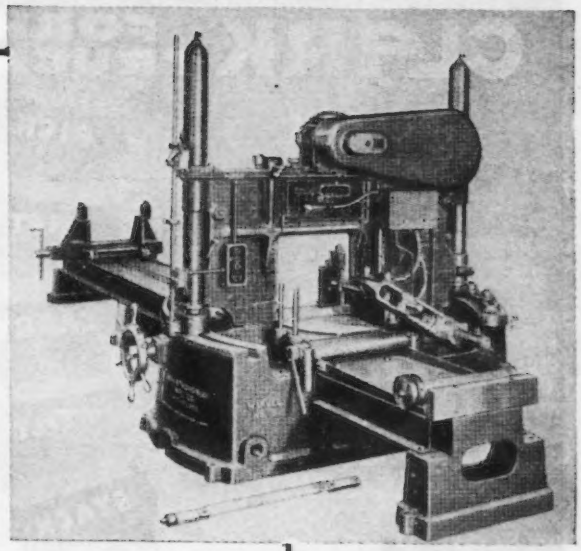
Sheets	19.00c.

*Includes annealing and pickling.

CUTS the Toughest Steels and Largest Sizes *easily.*



This giant hydraulic metal - cutting saw is more than just a larger hack saw. It is a new development in metal-cutting methods that introduces a new principle of metal sawing — the Roll-stroke blade action makes it possible to cut the toughest steels in the largest sizes easily and rapidly. It also permits a simple and efficient, very low pressure Hydraulic Feed System.

Built for heavy work, completely enclosed in heavy housing, this machine will stand up under the rough usage of the average steel mill warehouse and forge shop, where it will speed cutting-off, and reduce material loss.

MARVEL No. 18
Giant Hydraulic Hack Saw
Capacity 18"x18"

Cuts, angles up to 45° by simply swiveling upper machine housing.

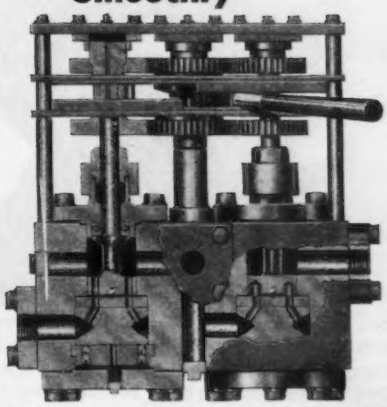
Hydra Venturi-Vacuum Valves

Operate Quickly Easily Smoothly



Hydra Venturi-Vacuum Valves embody a new principle—no springs or cups to bother with. Operation is instant and without noticeable effort. Installations in many industrial plants have reduced valve troubles to near zero and effected substantial economies.

GOOD SPRING DESIGN
was never MORE IMPORTANT!

With facilities crowded to the rafters, it's more important than ever to be sure every item in war production be designed and produced accurately, speedily and economically.

That goes for springs, wire forms, and small stampings, too! Helping to combine operations—to eliminate waste motion—to streamline production has been common practice with B-G-R spring engineers for years. Successful experience in meeting peace-time mass-production schedules puts B-G-R in a position to meet the super-production needs of the largest spring users in the world today—our fighting forces. Let B-G-R "spring-skill" help you, too!

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable.

(2) Price shown is for low-phosphorous iron; high-phosphorous sells for $28.50 at the furnace.

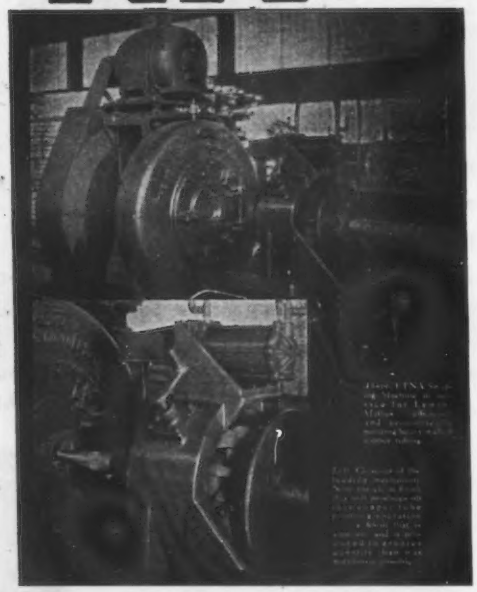
(3) E. & G. Brooke Co. permitted to charge $1.00 per ton extra.

(4) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 per cent to 2.25 per cent); phosphorous differentials, a reduction of 38c. per ton for phosphorous content of 0.70 per cent and over; manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

LEWIN-MATHES *Got the right answer at*

ETNA



They had a job of pointing heavy-walled copper tubing, and wanted to speed up the operation. Just how to do it didn't appear on the horizon, and so Lewin-Mathes did the safe and logical thing—they put their swaging job up to Etna.

The answer to that problem is illustrated on this page. It's a modern Etna Swaging Machine that points *more* copper tubes per hour in less time at less cost. If you have a problem involving tapering or reducing tubing and solid rounds—ask Etna about it.

Etna has the swaging machines from ⅜" to 4" and the experience to help you get the most out of this type of machine.

IF IT'S A QUESTION OF TAPERING, SIZING OR REDUCING OF ROUND SOLIDS OR TUBING... "Ask ETNA About Swaging"

ETNA MACHINE COMPANY

"HERCULES" WIRE ROPE — RED-STRAND — REG. U.S. PAT. OFF.

You Can Depend On "Hercules" (Red Strand) Wire Rope

Highlights of Quality

1. Acid Open-Hearth Steel Wire
2. Rigid Tests and Inspections
3. Correct Manufacturing Methods
4. Furnished in both the Round and Flattened Strand constructions, in either Standard or Preformed Type.

• • Results are what count, and the performance record of this wire rope continues to make and hold friends.

There is no guess work when you use "HERCULES" (Red-Strand) Wire Rope. It is designed and built to do specific jobs better . . . safer . . . more economically. If you will tell us how you use wire rope, we shall be glad to suggest the construction and type most suitable for your conditions.

PRICES

Ferromanganese

78-82% manganese, maximum contract base price per gross ton, lump size, f.o.b. car at Baltimore, Bethlehem, Philadelphia, New York, Birmingham, Rockdale, Rockwood, Tenn.

Carload lots (bulk)	$135.00
Carload lots (packed)	145.00
Ton lots (packed)	145.00
Packed, 200 lb.	138.00

Premium, $1.70 for each 1% above 82% Mn; penalty, $1.70 for each 1% below 78%.

Electrolytic Manganese

99.9% manganese, maximum base contract price per lb. of metal, bulk, f.o.b. shipping point, with freight allowed to destination. Size 1" x D.

	Eastern Zone	Central Zone	Western Zone
Carload lots	37.60c.	37.85c.	38.15c.
l.c.l. lots	39.60c.	38.60c.	40.65c.

Spiegeleisen

Maximum base contract prices, per gross ton, lump, f.o.b. Palmerton, Pa.

	16-19% Mn 1% max. Si	19-21% Mn 1% max. Si	26-28% Mn 1% max. Si
Carloads	$35.00	$36.00	$49.50
Less ton*	47.50	48.50	62.00

Electric Ferrosilicon

OPA maximum base price cents per lb. contained Si, lump size in carlots, f.o.b. shipping point with freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
50% silicon	6.65c.	7.10c.	7.25c.
75% silicon	8.05c.	8.20c.	8.75c.

Spot sales 45c. per lb. higher or 50% Si; 30c. for 75% Si. For extras and premiums see MPR 405.

Silvery Iron

(*Per Gross Ton, base 6.00 to 6.50 Si*)

F.o.b. Jackson, Ohio	$29.50*
Buffalo	30.75*

For each additional 0.50% silicon add $1 a ton. For each 0.50% manganese over 1% add 50c. a ton. Add $1 a ton for 0.75% phosphorous or over.

*Official OPA price established June 24, 1941.

Bessemer Ferrosilicon

Prices are $1 a ton above silvery iron quotations of comparable analysis.

Silicon Metal

OPA maximum base price per lb. of contained Si, lump size, f.o.b. shipping point with freight allowed to destination, for l.c.l. above 2000 lb., packed.

	Eastern Zone	Central Zone	Western Zone
96% Si, 2% Fe.	13.10c.	13.55c.	16.50c.
97% Si, 1% Fe.	13.45c.	13.90c.	16.80c.

Ferrosilicon Briquets

OPA maximum base price per lb. of briquet, bulk, f.o.b. shipping point with freight allowed to destination. Approximately 40% silicon.

	Eastern Zone	Central Zone	Western Zone
Car lots	3.35c.	3.50c.	3.65c.

Spot prices ¼c. higher per lb. of briquet. For premiums and extras see MPR 405.

Silicomanganese

(*Per gross ton, delivered, carloads, bulk*)

3.00 carbon	$120.00*
2.50 carbon	125.00*
2.00 carbon	130.00*
1.00 carbon	140.00*
Briquets, contract, basis carlots, bulk freight allowed, per lb.	5.80c.†
Packed	6.05c.†
Less ton lots	6.55c.†

*Spot prices are $5 per ton higher.
†Spot prices ¼c. higher.

Ferrochrome

(65-72% *Cr*, 2% *max. Si*)

OPA maximum base contract prices per lb. of contained Cr, lump size in carlots, f.o.b. shipping point, freight allowed to destination.

	Eastern Zone	Central Zone	Western Zone
0.03% carbon	25.00c.	25.40c.	26.00c.

Grainal, f.o.b. Bridgeville, Pa., freight allowed 100 lb. and over, maximum based on rate to St. Louis, per lb.	45c.
Bortam, f.o.b. Niagara Falls	
Ton lots, per lb.	45c.
Less ton lots, per lb.	50c.
Borosil, 3% to 4% boron, 40 to 45% silicon, f.o.b. Philo, Ohio, per lb. contained boron	$6.25
Ferrocolumbium, 50% to 60%, f.o.b. Niagara Falls, ton lots, per lb. contained columbium	$2.25
Less ton lots	$2.30
Ferrotitanium, 40%-45%, f.o.b. Niagara Falls, N. Y., ton lots, per lb. contained titanium	$1.23
Less ton lots	$1.25
Ferrotitanium, 20%-25%, 0.10 C max., ton lots, per lb. contained titanium	$1.35
Less ton lots	$1.40
High-carbon ferrotitanium, 15%-20%, 6%-8% carbon, contract basis, f.o.b. Niagara Falls, N. Y., freight allowed East of Mississippi River, North of Baltimore and St. Louis, per gross ton	$142.50
3%-5% carbon	$157.50
Ferrophosphorus, 18% electric or blast furnace, f.o.b. Anniston, Ala., carlots, with $3 unitage freight equaled with Rockdale, Tenn., per gross ton	$58.50
Ferrophosphorus, electrolytic 23-26%, carlots, f.o.b. Mousanto (Siglo), Tenn., $3 unitage freight equalized with Nashville, per gross ton	$75.00
Ferromolybdenum, 55-75 per cent, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum	95c.
Calcium molybdate, 40%-45%, contract basis, f.o.b. Langeloth and Washington, Pa., any quantity, per lb. contained molybdenum	80c.
Molybdenum oxide briquettes, 48%-52% Mo, f.o.b. Langeloth, Pa., per lb. contained Mo	80c.
Molybdenum oxide, in cans, f.o.b. Langeloth and Washington, Pa., per lb. contained Mo	80c.
Zirconium, 35-40%, contract basis, carloads in bulk or package, per lb. of alloy	15c.
Less ton lots	16c.
Zirconium, 12-15%, contract basis, carlots, bulk, per gross ton	$102.50
Packed	$107.50
Less ton lots	$112.50
Alsifer (approx. 20% Al, 40% Si and 40% Fe), contract basis, f.o.b. Niagara Falls, per lb.	7.50c.
Ton lots	8c.
Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.	
Car lots	8.75c.
Ton lots	9.25c.
Less ton lots	9.75c.

HAS SO FEW MOVING PARTS

The use of worm gear speed reduction in Reading Electric Hoists is the reason why there are only four moving parts. This means fewer wearing parts, both gears and bearings and a simpler more compact design. The result is a minimum of maintenance that can be handled by the average mechanic.

It will pay you to investigate the money saving features of Reading Electric Hoists. For full technical information write for Bulletin 1004.

Obsolescenc

Stuffed owls cannot fly, nor can obsolescent machinery be used in profitable production. *New competition* in the form of new markets, new products, new low prices, new materials, new methods, new companies and new equipment will force revolutionized production lineups. You'll be wise if you check over your situation now! Be ready to meet this multiple competition!

Most production lines will be modernized by a revamping of existing facilities. Perhaps it will be the addition of a Yoder Roll Forming Machine and Automatic Cutoff, A Tube Mill Line or some special metal working machine. The forward thinking of Yoder Engineers and the advanced design of their machines can help you to meet the new competition.

For over thirty years, Yoder customers have been saying, "Yo get the improvements first from Yoder."

A bulletin on our line of metal working machinery is availab In special cases, send rough sketches, notes and blueprints — w be glad to submit suggestions and cost estimates.

Cutbacks and Consumer Goods

HERE and there and from time to time we read reports of cutbacks in the war material program and of emergence of certain items from the critical materials list. And some people wonder why these things cannot be immediately reflected in an increased allowance of consumer peacetime products.

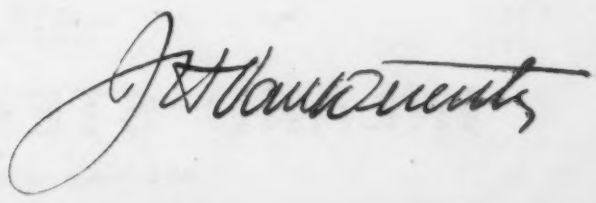
The answer to this question is twofold. One reason is that the war is not yet won and with its constantly changing pattern we cannot afford to tie up our manufacturing materials or resources in non-war work, even when a little slack develops here and there. We might, for example, find it expedient to cutback on steel for tanks because of current supply, or change in military strategy and terrain. This or any other change in unforseeable conditions may result in curtailing the output of a few steel furnaces for a time. But in a day or two or a week or a month, fresh demands may come especially with a war program that is growing in intensity and has not yet reached its peak and that may require the use of idle capacity at a moment's notice.

The second reason why cutbacks here and there do not immediately result in releases for consumer products is that very few of these are made of one material and most of them are made of many. Take washing machines for example. The largest amount of metal in them is iron and steel but there also are other materials like brass, tin, lead, zinc, leather and rubber and components such as gears, bolts and nuts and electric motors. Until you get an adequate supply of all these materials and parts, having enough of one of them does not do much good.

And then there is the element of labor which enters all products. Here again, having a surplus of one kind at one place does not solve the labor problem, because there are as many or even more kinds of labor than there are of materials and each product requires a certain kind. You can't shift labor from a steel mill into a washing machine plant and get what you need or vice versa.

It is true that we have had certain shutdowns of steel furnaces during the past few months. But as long as present requirements keep our steel producing capacity running at a rate of 95 per cent or better, there is not much chance to enlarge the area of distribution. Steel plants that run continuously at this rate may be compared to automobiles that run at 95 per cent of top speed, in that it does not do either of them any good and is likely to result in a breakdown.

From time to time we may get allotments of metals for civilian uses as the war goes on but I do not think it will be particularly noticeable until the big push is over over there. So don't expect too much until then and what you do get will be all the more welcome.



"Flying" bulldozers and scrapers will quickly repair this bombed airfield.

"Come on—Back the Attack —Buy War Bonds!"

Bulldozers That Fly

An airfield is bombed, but within a few minutes after the "all clear" signal is given Yankee engineers are at work repairing the damage with sturdy bulldozer and scraper units that are small enough to be flown anywhere by transport plane or glider. But repairing airfields is not the only job performed by these husky units—they also help build new airfields and vital supply routes, prepare camp sites, and perform many other chores so important to Victory.

Much of the steel used in these "flying" earthmovers is furnished by Inland to the La Plant-Choate Manufacturing Co., Cedar Rapids, Iowa. Producing steel for tough construction equipment is an old assignment to Inland steelmakers and metallurgists. A large tonnage of the steel shipped for this purpose before the war was Inland Hi-Steel—the steel that builds stronger and saves weight—the steel that will again be used for peacetime machinery when released from the demands of war.

NEWS FRONT

► To forestall the imposition of a mandatory 48-hr. week and the placement of Pittsburgh in the Group 1 critical labor status, the Labor-Management unanimously approved of the Pittsburgh Manpower Budget Plan, to be effective March 1.

Employers will be divided into three classifications: Those with direct Army, Navy or Maritime contracts will be permitted to hire men for both replacement and expansion needs; those whose activities are considered essential will be allowed to hire men for replacement only, and non-essential employers who will be permitted to hire women, veterans, boys under 18 and 1-A draft registrants awaiting induction.

► Copying the installation of 75 mm. gun on the Mitchell bomber, used with telling effect by Americans against the Japanese, the British are now putting a similar gun on the B-26, Martin Marauder.

How the Marauder gets off the ground with a 75 mm. gun, plus such very heavy ammunition, is a mystery. The Marauder practically has no wings, and seems to fly on its two propellers.

A 75 mm. shell fired from the gun would seem to have a flatter trajectory and greater accuracy than any form of rocket could have.

► Little Big Inch pipeline is now coming through after many weeks delay due to "defective pipe". Moving about 50 miles a day, the head of the column of heating oil passed Norris City on Feb. 8, and was expected at East Coast terminals late in February. Initial capacity (100-150,000 bbl. in March) is low because half of pumping stations are incompleted.

► Lockheed's cold water spray quench for aluminum uses a water-air atomizing nozzle to produce a dense fog. Uniformity of quenching which compares favorably with that of an immersion quench is thus obtained.

In all cases, ultimate tensile strength, yield strength and elongation meet or are above Army-Navy specifications. Distortion of parts like cowlings and thin contour skins is minimized by this spray-type quench.

► Properties of cold-blast pig irons have been closely duplicated by synthetic mixtures. Not only are the same chemical compositions fracture and mechanical properties achieved but chilling characteristics as well.

Mixtures are calculated to give a mean chemical and mechanical analysis closely approximating that of the cold-blast sample.

► The British have developed a new method of using guns in their night bombers to repulse German night fighters. British night bomber losses have dropped appreciably over the past month--not only a lower percentage but a lower total.

► In England there have been a number of cases of British soldiers committing robbery, so as to get money to enable them to compete with the far better paid U.S. troops for the favor of the girls they want.

► From the relief of Stalingrad to the present position in the Dnieper area, the Russian advance has been 2 miles per day. Also from Kharkov to the present Polish (Polesia) position, the Russian advance has been also 2 miles per day, except in one section where it has been 1.65 miles per day.

From this, a pessimist would assume that the best Allied advance from France to Germany would be 2 miles per day. And, it is some 800 miles from Paris to Berlin.

► Approximately 70 per cent of the auto parts and equipment manufacturers are supplying aircraft needs. Of these, 62 per cent expect to be in aviation work after the war, about double the number in this field prior to the war.

Few, however, expect aircraft parts to be a major factor in their operations.

When the Evansville Ordnance Plant cut in half its working force of several thousand men and women, personnel officers of neighboring plants were invited to go to the Chrysler plant and set up interviewing and hiring facilities.

► Attorney General Robert W. Kenny of California and Chad C. Calhoun, vice-president of the Kaiser Co. want the Geneva steel plant in private, independent hands, preferably Westerners. Sale of its finished steel products should be put on a new local basing point, they say, to eliminate the Pittsburgh-plus system.

Diecasting of Fuse Bodies

By H. E. SHEPARD
Assistant Manager, Rupert Diecasting Co., Kansas City

. . . By substituting zinc alloy die castings for brass fuse bodies formerly produced on screw machines, manufacturing costs are reduced and amount of scrap generated minimized. Procedure from die casting to machining and final packaging of the fuses for 20 mm. projectiles are herein outlined in detail.

FUSE bodies for 20 mm. projectiles needed by the Navy are being manufactured economically without sacrifice in quality at the Rupert Diecasting Co., Kansas City. Formerly, these bodies were produced from brass rod on screw machines in other plants. But the great demand for brass rod (in which the waste in chips is high for a part of this shape) and a belief that the job could be done with greater economy by die casting led to the development of the Rupert method.

This operation is indicative of what the die casting industry could accomplish with many parts not too economically produced by screw machines alone. In justice to the screw machine, it should be said, however, that its chief fault is that so much stock is converted into chips, as is done when bars are used. But the Rupert method minimizes scrap production by die casting. The product is finished by lathes converted to automatic chucking machines with very little metal converted into chips.

That the process has proved highly successful is indicated by the fact that the same basic method is now being applied to making larger fuse bodies from die cast zinc alloy for the 1.1 in. anti-aircraft projectile. These plugs are now being cast in the same shop. Both plugs are, in effect, hollow ogives having, at the inner end, an integral collar which is precisely threaded both inside and outside. As the die casting is step-cored and the outer ogive surface as well as the hole are cast to finished size and shape, only an insignificant amount of metal has to be machined off. Hollow sprues and runners, forming parts of the gates of castings as well as the chips from the machining operation are, of course, remelted and reused in the die casting machines.

An important factor in the success of the die casting method lies in the care used in making the 12-cavity dies employed. The cavities are made in cylindrical inserts in which the ogive shape is first hobbed to approximate size and then brought to precise size with a finishing hob. The o.d. of the block or insert is ground to be concentric with the ogive and then is pressed into a ground hole in the die block. This is highly important, as it insures a central cavity having its axis square with the die face and coaxial with the core pin. Without this precaution, it would not be possible to hold the close eccentricity limits imposed.

Several dies are in continuous use and they are checked four times an hr. to make sure that the eccentricity

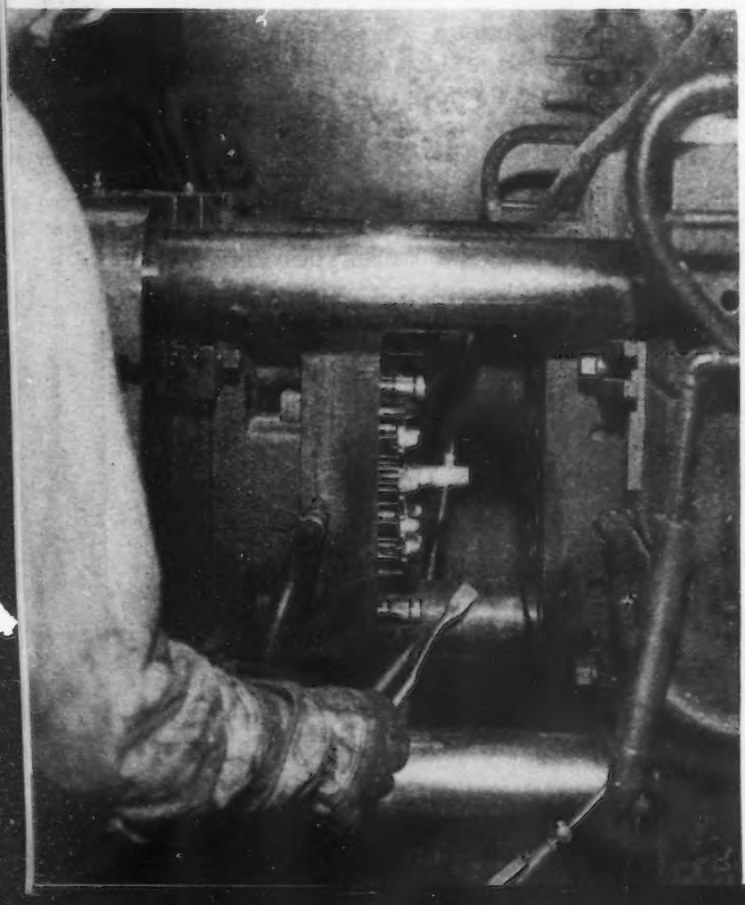

FIG. 1—Gate of castings in Zamak-3 (high-purity zinc alloy) are about to be removed from the casting die. There are 12 castings, made under air pressure of 1000 lb. per sq. in., on the gate which is shown already ejected by automatically operated ejector pins and is about to be removed with pliers.

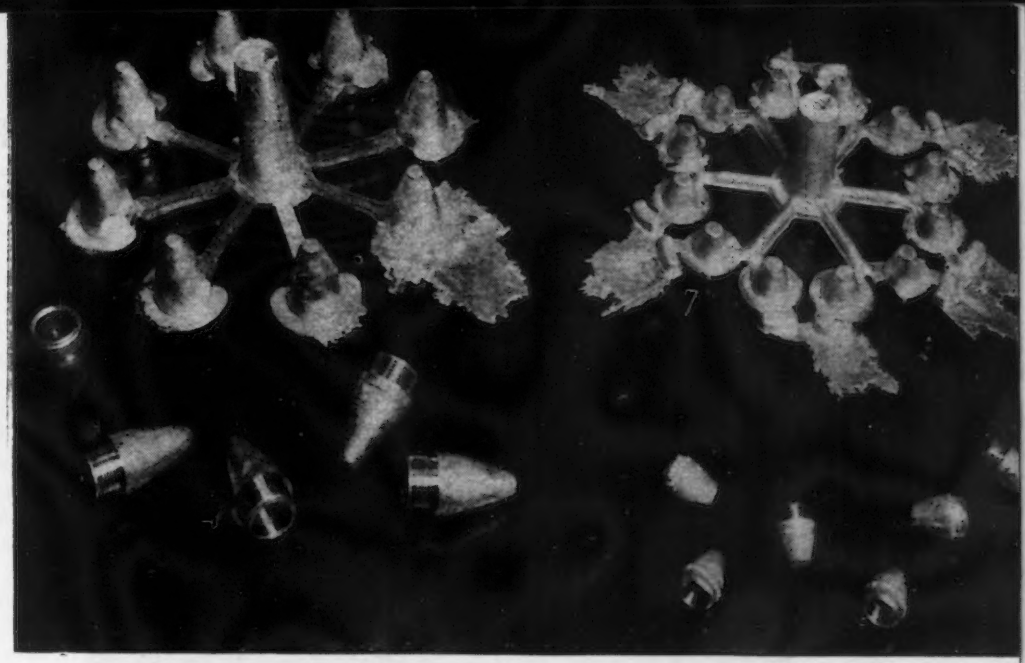

FIG. 2—Two gates of die cast fuse bodies as they come from the die. That at right has 12 castings for 20-mm. shell. The castings weigh 0.03 lb. each (about ½ oz.) when machined. At left is a gate of eight 1.1 in. castings which weigh about 2 oz. each when machined.

limits are held. In the machines for die casting, Fig. 1, it is possible to average 225 to 250 shots an hr., including time for inspections and other delays, and at each shot 12 castings are produced. Dies are provided with ejector pins which are automatically actuated as the dies are opened, ejecting the gate which the operator merely lifts out with pliers and quenches in water. The ejector pins are arranged to bear on runners, hence castings are not marred. These pins are actuated by a plate which contacts with stops on the tie rods of the machine.

Temperature of metal in pots is automatically controlled at 750 deg. to 760 deg. F. As a result of careful development, the gating and overflow wells (Fig. 2) are so arranged as to avoid porosity, especially in the tip of the ogive which is only 0.030 in. thick. The foregoing facts apply to the 20-mm. body to which all further details relate except as otherwise noted, although similar practice is followed in the larger fuse body casting. Pressure applied in injecting the metal is 1000 lb. per sq. in. Quenching helps to avoid warpage of the gate of castings as a whole.

The ogive surface is exceedingly

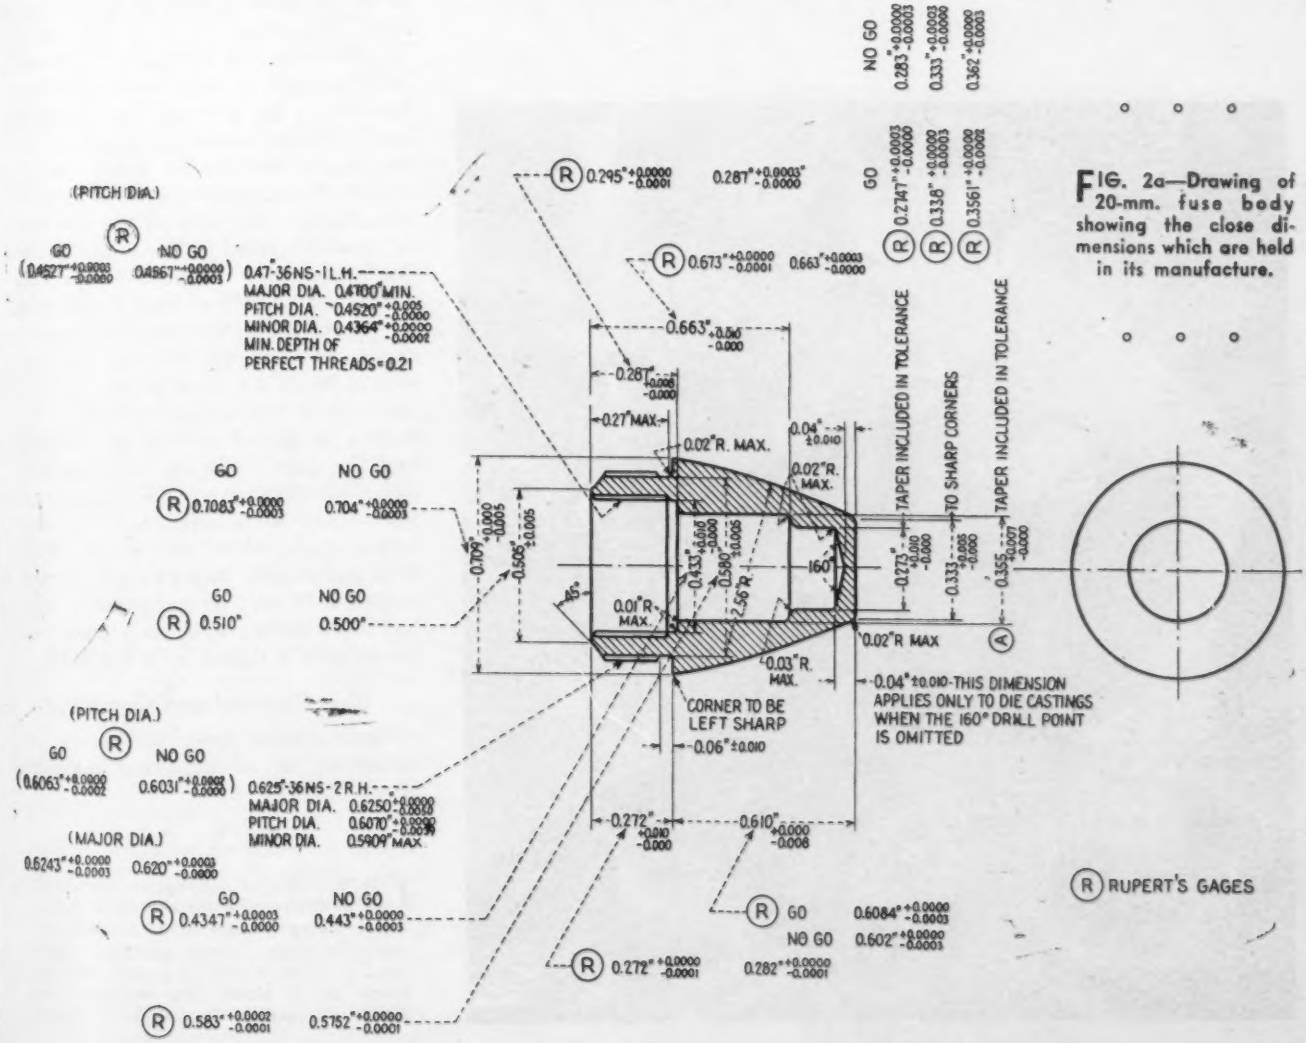

FIG. 2a—Drawing of 20-mm. fuse body showing the close dimensions which are held in its manufacture.

FIG. 3—Setup in Natco machine for tapping six castings at a time while still on gate and then tapping the other six after fixture (here shown in loading position) is indexed 60 deg.

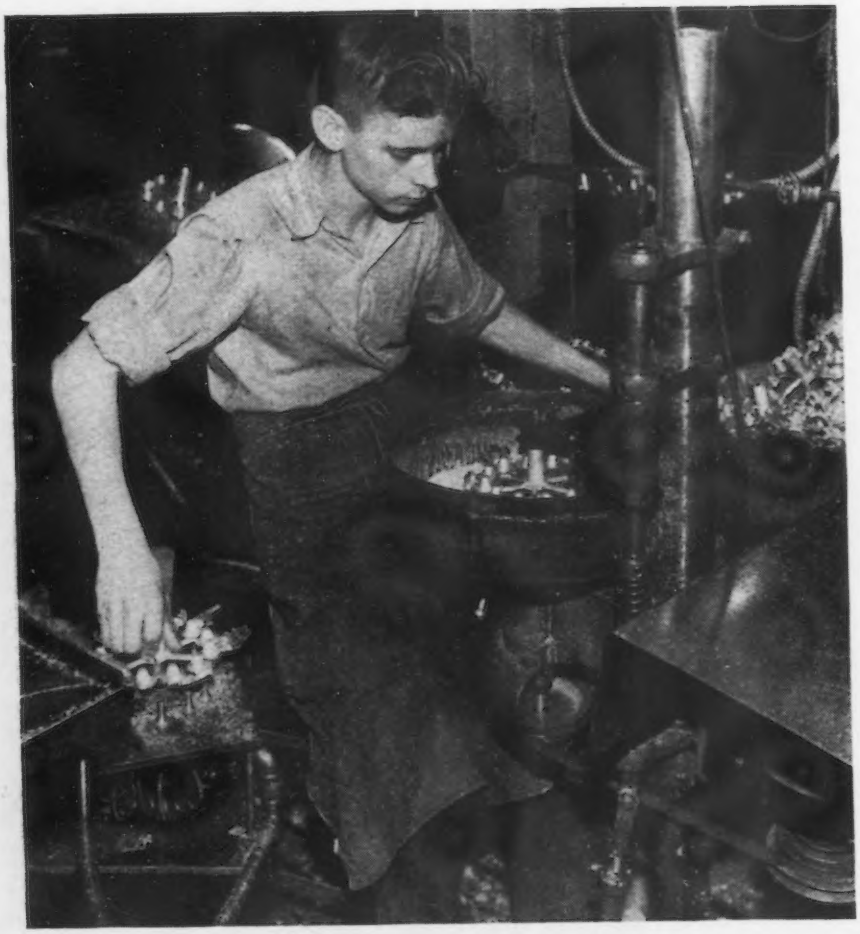
o o o

smooth, as cast, and does not afford a good chuck grip, a factor affecting later operations. This surface is not machined and hence must not be marred by chucking. Partly for this reason and partly to facilitate rapid tapping, the tapping operation is done before the castings are cut from the gate, as shown in Fig. 3, using a six-spindle Natco drill press. Each spindle is equipped with a five-flute left hand tap ground with an 8-deg. hook and having a cylindrical extension which pilots in the cored hole to insure concentricity of the thread. The thread is ½ in. 36 N.S. class 2 fit. Spindles carrying the taps are cushioned and no lead screws are required. Soluble oil is used as a coolant and the threads produced meet exacting standards, as indicated in Fig. 2a.

For accurate positioning of the work, the gate which must be free from warpage is set in a fixture having 12 correctly spaced recesses, one to fit the ogive of each of the 12 castings. This fixture is on a slide which is withdrawn for loading and pushed back against a stop when tapping. The fixture has a recess for the sprue and is pivoted about the sprue center. In tapping the first six holes, the fixture is swung about the pivot against one stop and the table of the machine is raised by pedal to clamp the bodies firmly in their respective recesses against a pressure pad as tapping proceeds. Then the table is lowered, the fixture indexed 60 deg. and the second set of six fuses is tapped when the table is again raised. Finally, the fixture is moved to loading position and the gate (with the runners still attached, turning of the castings is prevented) is removed and dropped into a chute. With this setup, about 3750 gates, each with 12 castings, are tapped in 8 hrs., or almost 6000 tapped holes an hr., which is a high rate for so good a thread as is specified.

Chip Removal and Coolant

Gates sliding down the chute are picked up at an adjoining machine



o o o

FIG. 4—Gate of castings in centrifuge which throws off chips and coolant, the latter being caught and drained to sump for reuse. Under operator's right hand is a fixture with 12 nozzles through which air is blown into threaded recesses of castings for removing chips.

which is actually a centrifuge made from an inverted drill press, Fig. 4, with a pedal-operated clutch and brake. The operator drops the gate onto a light chuck which spins the casting. Any soluble oil is thrown off and is caught by the surrounding housing and drained back to the sump of the Natco machine for straining and recirculation. The gate is then dropped onto a fixture having 12 air nozzles spaced opposite the tapped holes in the 12 castings. As the casting is seated an air valve is automatically tripped and air jets, one entering each casting, blow out any chips and coolant remaining in the holes. Then the gate is dropped into another chute leading to a punch press.

This press, Fig. 5, is equipped with a 12-cavity trim die into which the operator sets the gate. The ram of the press carries 12 floating punches which center themselves, one in each casting, as the ram descends and push the 12 castings through the holes in the trim die, cutting them from the gate and shearing off flash. Castings drop through the press bed into a chute down which they slide into a pan for removal to the next operation. Gates and flash remaining on top of the die slide through the back of the press and down another chute into a tote box for return to melting pots of casting machines.

All remaining machining operations, which include machining the shoulder and a groove and cutting the external thread, are done in Logan lathes which have been converted into automatic single-spindle chucking machines, partly air operated. Although these machines, once they are set up and functioning as intended, require constant attendance, all the operator need do is load a small vertical magazine out of which the plugs are fed automatically into the chuck. They then pass through the machining cycle and are ejected, all automatically, at the rate of 2000 pieces an hr. Considerable experimental work was required, however, to develop the feeding mechanism and automatic tool controls, partly because it is necessary (to avoid marring the ogive surface) to hold the latter in the chuck with sufficient pressure for the chuck to drive the piece by friction.

The chuck is mounted, of course, on the end of the lathe spindle. It is provided with a recess ground to fit the ogive. At the center of the chuck is a plunger which is pressed forward by a spring and acts as an ejector. When the piece is loaded, the plunger is pushed inward until the piece seats

o o o

o o o

firmly in the chuck which, of course, centers the piece and positions it endwise.

Automaticity and timing are controlled by a special lay shaft driven by a V-belt driven by a reduction gear. The V-belt runs from a pulley at the rear end of the lathe spindle. (See Fig. 6.) A positive clutch is placed between the reducer and the short lay shaft, but is needed only when the automatic elements are to be disconnected. Cross slide traverse is actuated by a cam from the same shaft engaging a roller. On the slide are two tool holders. That at the front carries a circular type of forming tool which, as it is fed forward, faces the shoulder at the inner end of the ogive and cuts a groove in the shank next to the shoulder where the thread terminates.

When these cuts are completed, the cross slide reverses and the second circular tool, a two-point thread chaser, is fed from the rear. Also on this tool holder is a brass half nut designed to engage a lead screw cut on the outside of the chuck carrying the work. This nut advances the tool longitudinally as it chases the thread. At the same time, a spring plunger is compressed and, when the tool finishes the thread and is disengaged by the cam reversing the cross slide, the spring returns the chaser against a stop which controls its position at the start of the threading operation on the next piece. Cutting of the thread completes the machining and when the tools are both disengaged, the work is ejected and falls into a chute and thence into a box back of the lathe bed.

Feeding of the bodies from the magazine, which is merely a vertical track into which the parts are fed by hand, is accomplished as follows: The tail stock shown in Fig. 7 is equipped with a live center which can be advanced, for loading, and withdrawn at injection, by a plunger in an air cylinder fastened to the tail stock. Motion of the plunger is controlled, of course, by action of air valves, which is coordinated with machining events of the cycles. The air valves are operated by solenoids and the latter are operated by a micro-switch. These are actuated by a rocking shaft mounted in bearings which hold it parallel to the ways on the bed of lathe.

Rocking of the shaft and the consequent functioning of the switches are effected by the same cam disk which operates the cross slide, although a different cam surface controls the cam follower connected with the shaft. On some lathes, including the one shown in Fig. 6, the cam surface for operating the switches is on the periphery of the cam disk. In other machines, it is a track in the face of the cam disk opposite the track for cross slide operation. The switches are at the opposite end of the rocking shaft, below the air valves, which are next to the air cylinder. The hookup is such that, when a machining cycle is finished, one valve relieves the pressure on the plunger which holds the piece in the chuck under 100 lb. pressure, and opens a valve which causes the plunger to be withdrawn.

o o o

o o o

FIG. 9—Unloading a carrier in which machined fuse bodies have been advanced through a trichlorethylene degreaser.

The ejector spring back of the work then ejects the piece.

As the live center is withdrawn, the next casting falls into position to be moved into the chuck and, when the air valves are reversed, the ram and center move forward and push the casting into the chuck where it is locked, thus starting another cycle.

Checking for Dimensional Control

Each chucking machine is checked every 10 min. to make sure that the pieces turned out come within required dimensional limits. The operator assigned to this work takes about five castings from the pan and puts them through the gages shown in Fig. 8. These check both diameters and lengths and there are also go and no-go thread gages. If any parts are found off size, the machine is stopped and the cause of the faulty dimension is corrected, all parts remaining in the pan being checked. If all the parts selected at random for inspection pass the latter, the lot is approved and is shifted to the degreaser shown in Fig. 9.

This machine is equipped with perforated carriers. When a carrier is filled with the parts and the hinged door closed, it automatically travels through the machine in which the container is rotated slowly as the work is brought into contact with the trichlorethylene in spray and vapor form. This results in removing chips and grease. When the carrier returns with the cleaned parts, it is emptied into a chute and loaded into trays for delivery to the inspection bench, Fig. 10. Under the central strip of this unusual bench is a slow-moving belt conveyer running about 2 in. below the top. Partitions divide the space between top and belt into four alleys above each of which there are four sets of openings. The four in each set are marked, respectively: "Good", "dirty", "scrap" and "burrs." There are inspection spaces beside each set of openings and these spaces afford room for four girls at each side of the bench, the top of which has two shallow bins for parts ready for inspection.

Inspection at this bench is purely visual and the girls drop the castings into the holes corresponding to the condition of the part. As the belt advances, it discharges the parts from each alley into a corresponding container. Good parts, that is, those passing visual inspection, are ready for final inspection. Those which are dirty are cleaned and those which have burrs go to a bench where the burrs are removed. Scrap parts,

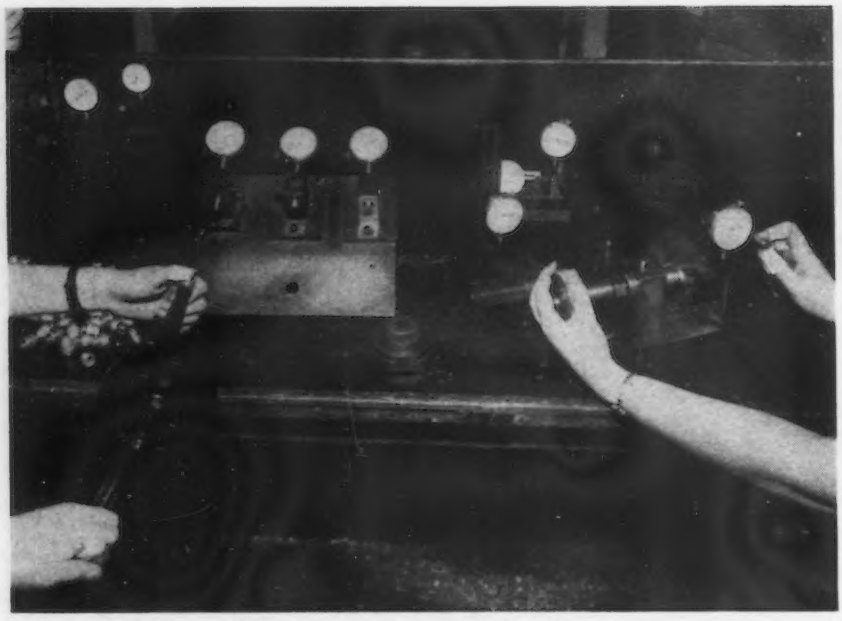

FIG. 11—Gages used for final inspection, including those for measuring eccentricity. Crank "grinder" is used for gages which must be turned into or over threads and saves screwing them in with fingers.

amounting to less than 3 per cent, go to the smelting department for remelting.

Parts which pass visual inspection are placed in trays containing 3000 castings each. From each tray 100 castings are taken at random and are checked on all dimensions. If any rejects are found in this hundred, all remaining castings in the tray are inspected for the dimensions found faulty in the lot of 100. Rejects are remelted but the other castings are ready for government inspection which follows immediately.

Gages used in the final test are shown in Fig. 11. Go thread gages are mounted on the spindle of an ordinary kitchen grinder and are turned by a geared crank while the casting is run into or over the gage. This is much faster than screwing and unscrewing the castings manually. Eccentricity is checked with dial gages mounted on a holder having a hand wheel and a chuck to receive the work. A hinged lever projects into the hole and is pivoted so that the dial gage, bearing at the opposite end of the lever, measures the eccentricity. The gage and lever are on a slide and are so arranged that the lever is lifted automatically as it is moved to the three steps in the hole. Other dial gages check other dimensions, including various lengths.

After passing government inspection and weight-counting, the parts are transferred to the bench, Fig. 12, where they are first fed by hand into a rotating holder turning in a horizontal plane. This machine carries the parts past a marking die as they turn on their own axes. This die applies the part number and maker's trademark, after which the parts are delivered down a chute to a packing bench, which has some unusual features.

Cartons hold 1000 fuse bodies set in 10 layers with cardboard between, the individual castings being held apart by eggcrate type separators, each with 100 recesses. To facilitate loading, an opening the size of the expanded separator is made in the bench top and below it is fitted to the four sides of a box. The bottom or fifth side of this box is made movable vertically by a lever which fits in 10 notches corresponding to the 10 tiers of castings. To start loading, the bottom is adjusted one tier below the bench top, is covered with a square of cardboard and a separator is inserted. A double handful of castings

o o o

FIG. 12—Setup for marking parts with number and trade mark (rotating disk at back) and for packing cartons with a finished part in each opening of the separators, one of which is in recess at center of bench. Lever in foreground lowers and raises packed separators.

o o o

is then spread over the separator and castings fall into the respective openings or are placed in any not thus filled. Then the tier is dropped one space and another card and separator are added and filled. This is repeated until the 10 tiers are filled. Then a carton is inverted over the load it is to receive and the load is lifted by the lever, filling the carton, which is then slid off (the bottom card being at bench height) and turned right side up, sealed and marked for shipment. The advantage of this arrangement is that the operator is always working at bench height and never has to reach down into the unfilled carton. Seventy to 80 boxes can thus be filled in an 8-hr. day.

More recently put into production is the much larger 1.1 in. body for anti-aircraft applications. In this case, the castings, which weigh about 2 oz. when machined, are cast eight on a gate from zinc alloy, as shown in Fig. 13. In this case, the casting is done in a larger machine operating with hydraulic injection at about 200 shots an hr., the pressure applied to the metal in this case being 2500 lb. per sq. in. The castings are sheared from the gate eight at a time in a punch press before being tapped or otherwise machined, the machine work being done later in another plant. These bodies are cast with flats, serving as wrench holds, near the base of the ogive, and this facilitates holding them in a chuck.

Four of these castings are shown in Fig. 14, together with a gate and separate castings of an interior part which is cast of aluminum alloy in a cold-chamber machine. Each of these parts has an off-center core of odd shape.

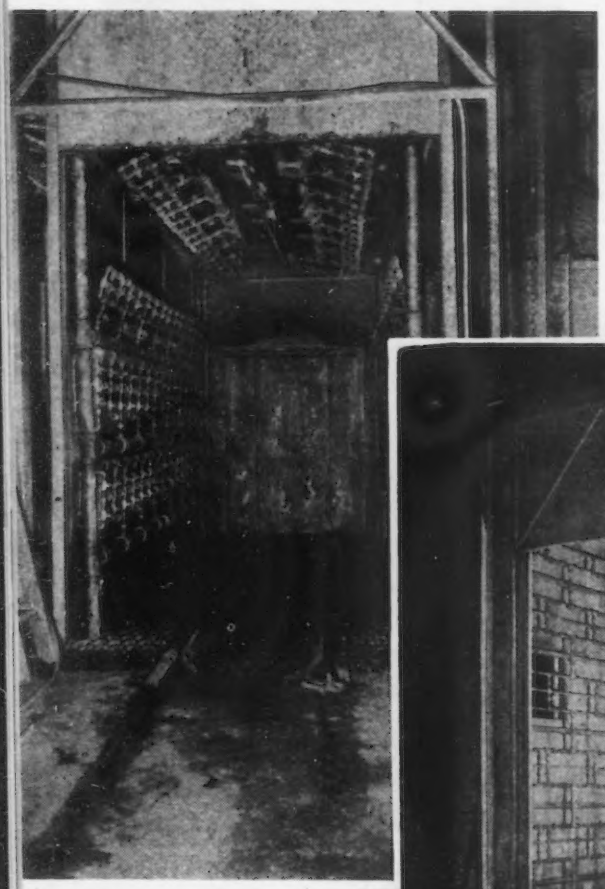
Cold Water Spray

By V. S. SORENSON
Process Engineer,
and
F. O. RIEK
Plant Engineer,
Lockheed Aircraft Corp.
(Factory A, formerly Vega)



ABOVE

RIGHT
FIG. 3—Load rack in position in quench booth No. 2.

THE problem of quenching aluminum alloy sheet in heat treatment has always presented many difficulties in the form of distortion and corrosion resistance. A quench has been developed at Lockheed Aircraft Corp. which eliminates a great deal of the distortion trouble and produces results which consistently meet Army and Navy requirements for physical properties and corrosion resistance.

The method involves a cold water spray quench which differs from ordinary spray quenches used in the past in that a water-air atomizing type nozzle is used which produces a dense fog rather than a spray. A filter system keeps the system consistently clean. Uniformity of quenching which

Quench . . .

for Clad Aluminum Alloy

. . . The quenching method described herein, in which a dense fog is used rather than a spray, results in corrosion-free material, and eliminates much distortion trouble. Uniformity of quenching, which compares favorably with that of an immersion quench, is obtained.

compares favorably with that of an immersion quench is thus obtained, and tensile requirements of AC Specification 11067A, Table III are fully met.

Two spray quench booths numbered No. 1 and No. 2 were installed for experimental work. No. 1, the interior of which is shown in Fig. 1, was 5 ft. 2 in. x 12 ft. x 6 ft. 11 in. The nozzles were arranged in five runs of 15 nozzles each, two runs of which were located at the top of the booth. The three side runs were arranged as follows: 22½ in. from the floor, 19 in. above the first run, and 19 in. above the second run. Nozzles in each run were 8½ in. apart. The total spraying system included 120 nozzles.

The No. 2 booth was considerably larger, with dimensions of 11 ft. 1 in. x 16 ft. x 9 ft. The total spraying system was comprised of 450 nozzles arranged as follows: Overhead, 3 runs of 18 nozzles each; bottom, 2 runs of 18 nozzles each; each side, 10 runs of 18 nozzles each. Fulflo filters were installed on air and water inlet lines, filtering to 2½ microns each.

Shown is the sheared edge of the specimen and a portion of the flat surface of the metal from which the cladding was stripped.

o o o

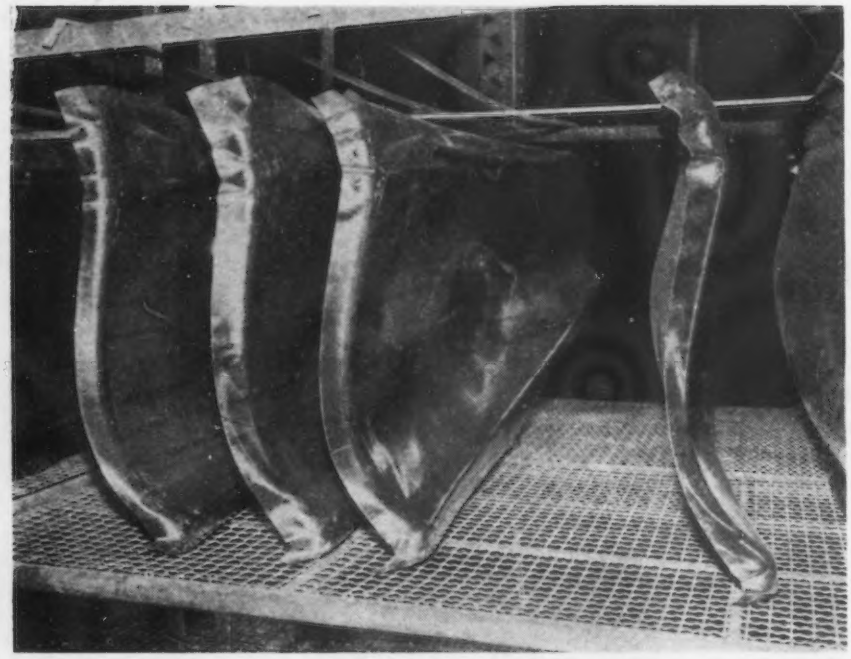

FIG. 6—Photomicrograph of 0.040 specimen and a portion of the flat cladding booth No. 2, with quench water quench air pressure of 40 lb. per sq.

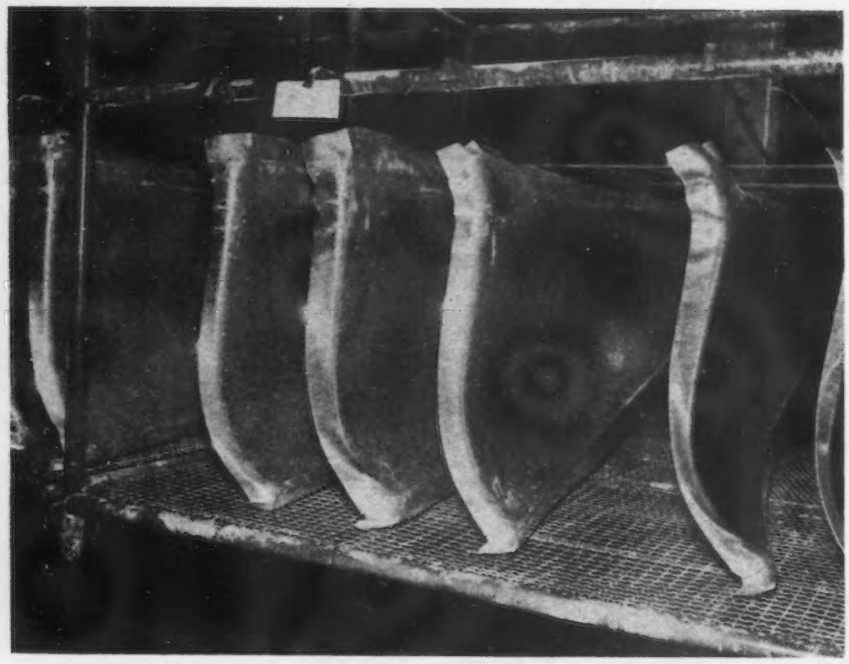
o o o



LEFT

FIG. 7—At top are thin skins before heat treatment. Below are shown the same skins after heat treatment using spray quench.

o o o

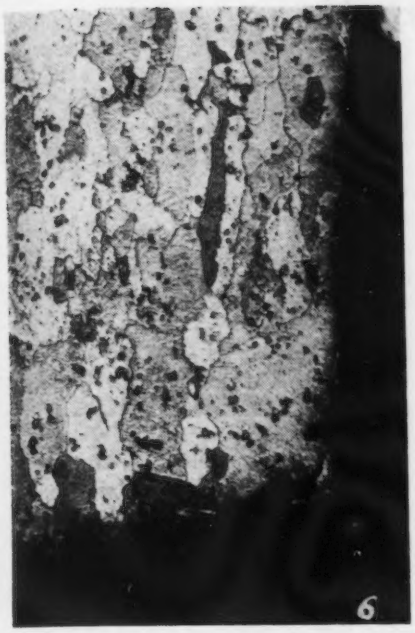
In both booths, the average temperature of the quench was 65 deg. F. The time required to transfer the load from the furnace to the quench was 7 to 10 sec. The load in the quench booth, and the dense quench spray obtained are shown in Figs. 3 and 4.

Tables I and II show physical properties obtained with the new quenching equipment. In all cases, the ultimate tensile strength is above Army and Navy requirements. Yield strengths on test specimens also were above minimum requirements with

o o o

LEFT

FIG. 8—Typical cowling parts, for which spray quench is used.



in. 24SO material, spray quenched in pressure of 135 lb. per sq. in. and in. Shown is the sheared edge of the surface of the metal from which the was stripped.

o o o

the single exception of a specimen quenched in booth No. 1, where the yield was 270 lb. under minimum, which is negligible since the stress strain recorder used could be subject to this much error.

Elongation meets the requirements of Army-Navy specification AN-A-13 in all cases, and meets Air Corps specification 11067-A with one exception from quench booth No. 2, where the elongation was 2 per cent under the 15 per cent required. This specimen was badly scratched, which could have been a contributing factor in affecting tensile tests for elongation.

Corrosion resistance was satisfactory in all cases using the cold water spray quench. Poor corrosion resistance has always been the main argument against a spray-type quench. These tests definitely show that when the quench is properly designed, the difficulty can be eliminated. Photomicrographs, of which Figs. 5 and 6 are samples, taken after accelerated corrosion tests show no evidence of intergranular corrosion. Satisfactory grain contrast is present.

Typical parts made from the spray quenched material are shown in Figs. 7 and 8. It can readily be seen that cowling, thin contour skins, etc., when quenched in a cold water immersion quench would be subject to a great deal of distortion.

* Material badly scratched.

Development of High Yield Strength in Clad 24S

. . . Four 24S clad aluminum alloy tempers are here discussed, with a description of a precipitation aging process that is sound from a production standpoint. Data on the increase in physical properties of the four tempers are included.

CONSOLIDATED Vultee Aircraft Corp. is now using a process which causes a considerable increase in the yield strength of clad 24S over that obtained by the usual type of heat treatment. This process consists of precipitation aging at elevated temperatures and may be performed on various tempers of the material.

For purposes of clarity, 24S-T temper is referred to herein as 24S-T_3, the subscript standing for the approximately one per cent reduction of area given this material, after heat treatment, for straightening.

Clad 24S-T and 24S-RT may be used without further treatment but 24S-O must be given a solution heat treatment at 910 to 930 deg. F. (Fig. 1) followed by quenching in cold water from this temperature. The resulting temper of the alloy is here referred to as clad 24S-T_6, the subscript indicating that the material has been subjected to no reduction in area following heat treatment.

o o o

FIG. 1—Heat treated 24S-O material being lifted from 920 deg. F. molten salt bath to be quenched in cold water.

In making aircraft parts, stringers in the shape of "hat" or "Z" sections are frequently made in lengths up to 20 ft. Fig. 2 shows the first step in this operation. These sections are formed from 24S-O material, the finished sections then being subjected to the solution heat treatment and quench described above. These parts are badly distorted by the heat treatment and in order to straighten them it is necessary to stretch them as shown in Fig. 3. Tests made in conjunction with the stretching operation have shown that by stretching to a permanent elongation of 3½ per cent, the yield strength of the material is increased substantially over the original 24S-T_6 condition. Fig. 4 shows the effect on the yield strength of various amounts of stretching. Parts of this type are therefore given a stretch resulting in a permanent

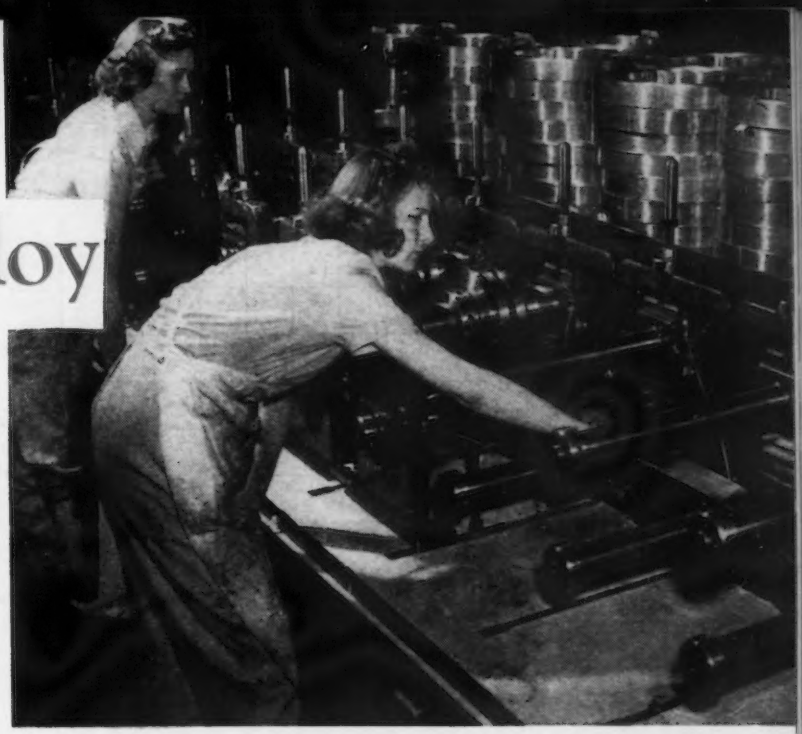
Consolidated Vultee Aircraft Corp.
Fort Worth Division



elongation of 3½ per cent, plus 0.5 per cent, minus 0.0 per cent. Springback of ½ per cent is allowed for in stretching this material. Material given this treatment is designated as clad 24-RT.

The minimum physical properties obtainable in each of the five tempers are shown in Table I for 0.091 in. sheet stock. The increase in yield strength caused by stretching the 24S-T_0 3½ per cent is evident.

Thus there is available material in four tempers; 24S-T_0, 24S-T_3, 24-RT and 24S-RT, which may be used without further processing. However, it has been found that when any one of these four tempers is subjected to temperatures of 325 to 425 deg. F. for periods of 20 to 30 min., respectively, the yield strength undergoes a decided increase. Curves showing the relationship between time and temperature for each of the tempers, to obtain maximum yield, are shown in Fig. 5.

The phenomenon may be explained as follows: The 24S aluminum alloy is a precipitation hardenable alloy in which solution heat treatment causes complete solid solution of the copper, which is maintained during the quenching operation. Upon aging at room temperature for several days, precipitation of the hardening con-

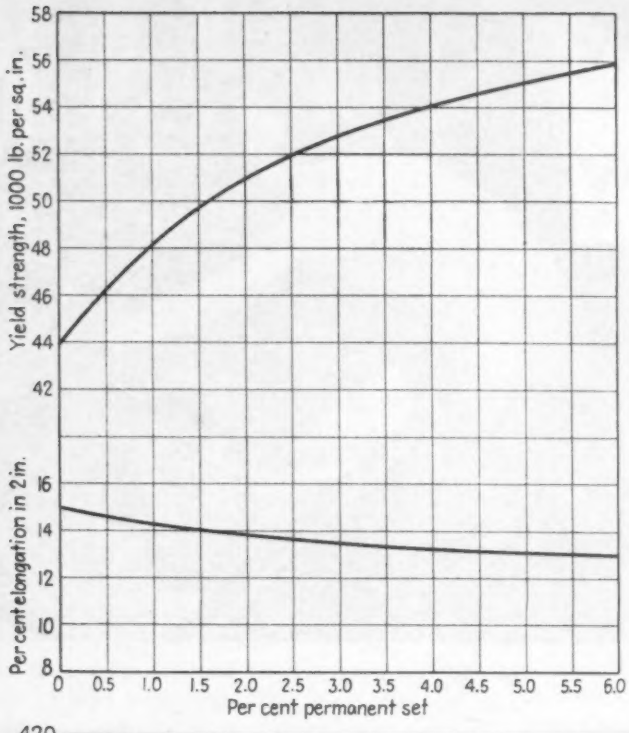

FIG. 4 — Effect of stretching 24S-T aluminum alloy.

stituent, Cu Al_2, takes place to the extent of approximately 50 per cent, and causes the material to develop hardness. By heating at some elevated temperature the precipitation is forced toward completion resulting in a material in which the Cu Al_2, or hardening constituent, is almost completely precipitated from the solid solution.

To take advantage of this phenomenon it is necessary only to select some heating cycle of time and temperature which lends itself well to production. Tests have been made which show that the effects of heating are cumulative and that the highest yield strengths are reached on a smooth curve resulting in a peak of short duration when high temperatures (400 to 425 deg. F.) are used, and of very long duration when low temperatures (325 to 350 deg. F.) are employed. Fig. 6 illustrates this point by showing the effects of various temperatures on clad 24S-T_0 for

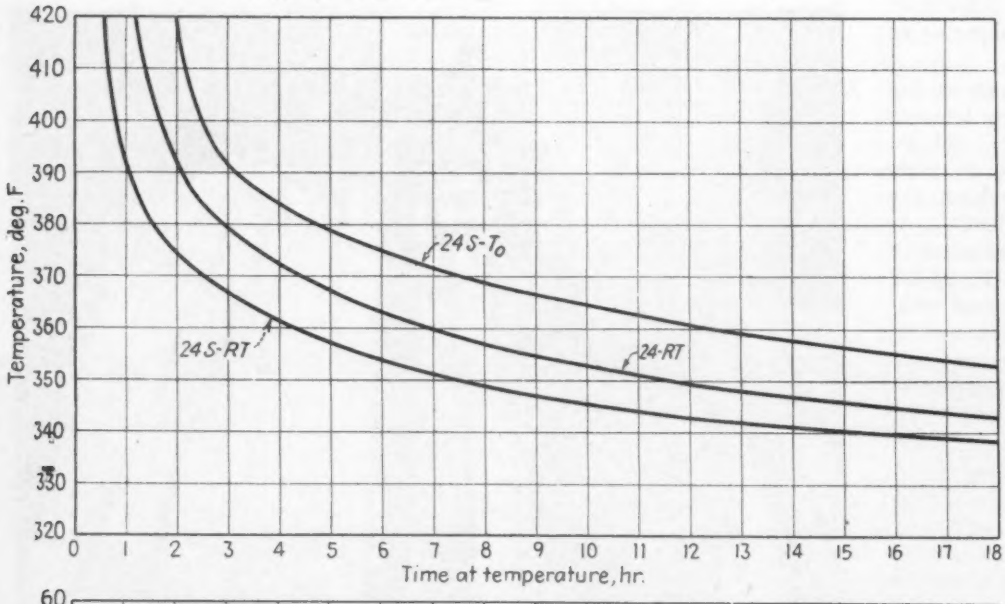

FIG. 5 — Relationship between aging time and temperature, in obtaining maximum properties of 24S-T_0, 24-RT and 24S-RT aluminum alloy.

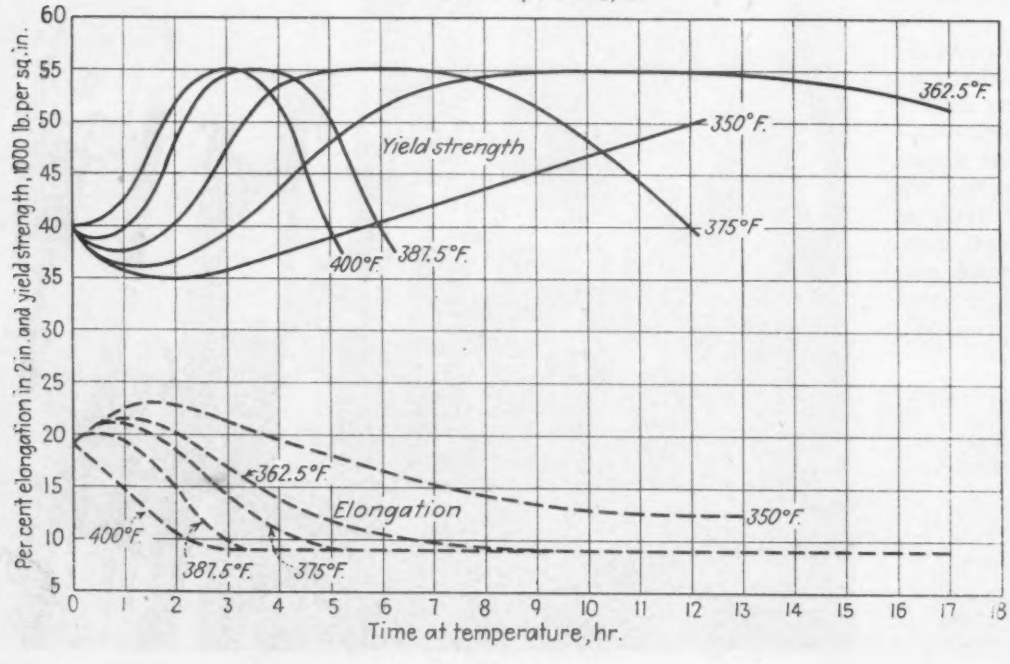

FIG. 6 — Effect of heating 24S-T_0 for various lengths of time at varying temperatures.

lengths of time ranging from 0 to 12 hr.

Moreover, tests have shown that the position and length of the peak of the aging curve is dependent not only upon time and temperature but also upon the amount of cold work inherent in the original material. For instance, clad 24S-RT, which has been cold reduced 5 to 6 per cent, will undergo complete aging in a shorter period of time than will 24S-T_0, which has not been subjected to cold work. Evidence of this fact is shown in Fig. 5.

It would, therefore, be necessary for a time-temperature cycle, that is sound from a production standpoint, to be devised in such a manner that the maximum properties might be obtained, in all of the tempers, by the use of a short period of time and a controllable temperature, without danger of over or under aging any of the material. Tests have indicated that a temperature of 365 deg. F. ± 5 deg. will achieve the desired results over a period of 7 to 10 hr. U. S. Army Air Corps Specification No. 11354 recommends aging clad 24S-T_0 for 10 hr., 24S-T_1 for 9 hr., 24-RT for 8 hr., and 24S-RT for 7 hr., allowing a ± 15 min. tolerance on the aging time. However, it has been found that aging all tempers at 8 to 8½ hr. at this temperature will produce satisfactory results. Curves showing the effects of heating the several tempers at 365 deg. F. for various lengths of time are shown in Fig. 7.

RIGHT

o o o

BELOW

FIG. 8 — This artificial aging furnace at Consolidated Vultee Aircraft's Fort Worth plant is the largest in use by the nation's aircraft industry.

In order to identify the material after aging, U. S. Army Air Corps Specification No. 11354 has decreed that certain designations shall be used:

Before Aging	After Aging
24S-T_0	24S-T80
24S-T_2	24S-T81
24-RT	24S-T84
24S-RT	24S-T86

This specification also covers the processing of all tempers and lists the minimum physical properties required of aged material. Table II lists the designations used for each temper processed and gives the minimum properties for each. As indicated by the table, the aging process causes some increase in the ultimate strength, as well as in the yield

strength. Some decrease in elongation is experienced, although this does not affect the usefulness of the material.

The precipitating aging process has been found extremely valuable for obtaining higher design allowables in aluminum alloys and Consolidated Vultee has installed a large car type furnace for such aging. This furnace, which measures 40 ft. x 9 ft. x 8 ft. and can be automatically started, is gas heated by three burners and has air circulation controlled by three 10 hp. fans which force heated air through the bottom. The furnace load is placed on either of two cars operating through doors at both ends of the furnace. The furnace is capable of handling about 15,000 ft. of "Z" stock at one time or approximately 6500 lb. of aluminum alloy. When fully loaded, the furnace will return to its original temperature of 365 deg. F. within 20 min. Temperatures are controlled within ± 3 deg. F. The furnace is operated 18 hr. a day, with two full furnace loads a day processed.

Most recent tests on the aging process have indicated that riveted assemblies may be aged. According to the above aging cycle when 17S-T rivets are aged they undergo a slight increase in shear strength while A17S-T rivets are not materially affected. It is therefore possible to assemble completely many small parts before subjecting the material to the aging treatment.

Unclad 24S aluminum alloy may be given the aging treatment described above, with corresponding increase in physical properties, but at present only clad material is processed in this manner, since maximum corrosion resistance is desired.

TABLE I

Minimum Properties of 0.091 In. Clad 24S Sheet Before Aging

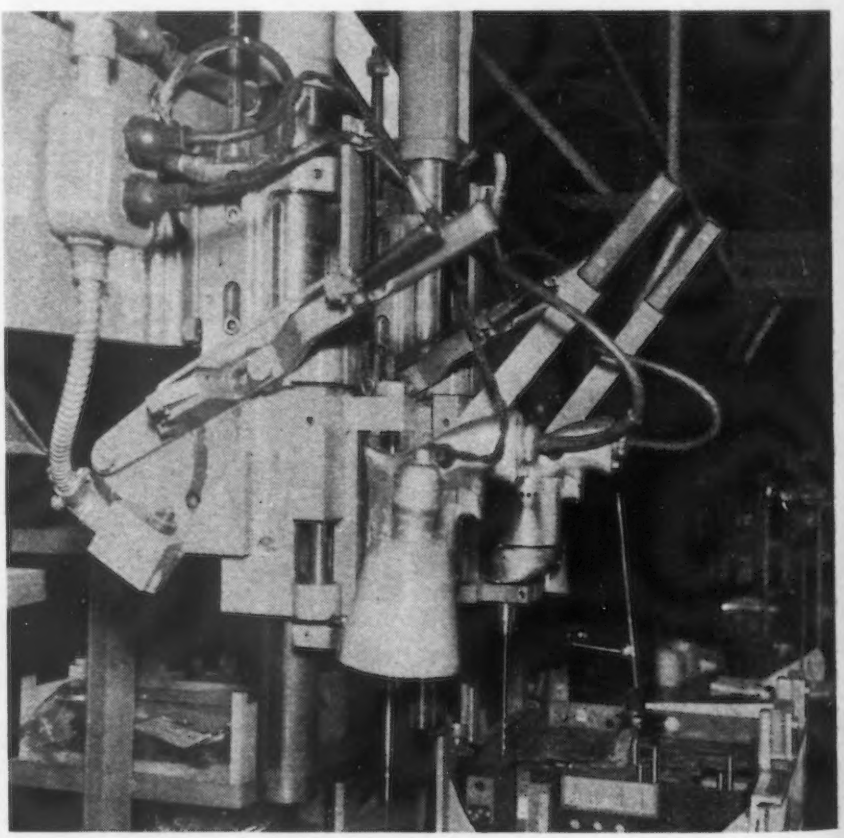
Drill Press Hung from Ceiling

WHEN the AC Spark Plug Division of General Motors began setting up a progressive conveyorized system to assemble a British-designed bombsight in mass production, two points on the line were found where drill press work was needed. However, no standard drill press on the market was found suitable for these installations, because of wide overhang interfering with the conveyor line. To use such a unit meant extra handling and lifting of parts, disrupting progressive assembly flow of the bombsight.

To get away from this wide overhanging problem on a standard press, AC officials designed and built a holding fixture for small electric drills, and mounted the fixture on the ceiling. This eliminated all posts and other obstructions beneath the drill, making it easy not only to get the part from the conveyor, but also to operate.

Another interesting feature of the set-up is the automatic switching arrangment used to start the drill and turn a light onto the work. A Micro Switch is mounted on the side, in position where it is tripped by the lever bringing the balanced drill head down into position for work. A second lever on the other side of the drill controls the actual drilling.

In the photograph shown here, the positioning control coupled with the switch-on arrangement is shown in the foreground. On the far side of the machine is the lever used in actual drilling. In immediate background is a second drill with an identical set of controls.



THIS multiple piercing die is believed to contain more closely coordinated holes than any die previously used in aircraft work, according to Boeing engineers. The 388 punches shown pierce rivet holes in five different sections, including two sizes of flat sheets, two different angle sections and extruded T-sections.

Multiple Piercing Die For Aircraft Parts

. . . In order to coordinate the rivet holes in the assembly of the 10 pieces which make up a catwalk for the Boeing Flying Fortress, a flexible piercing die has been devised which will accommodate itself with minor adjustments to piercing of flats, angles and T-sections. Use of manually operated side guides or stock pushers largely makes this possible.

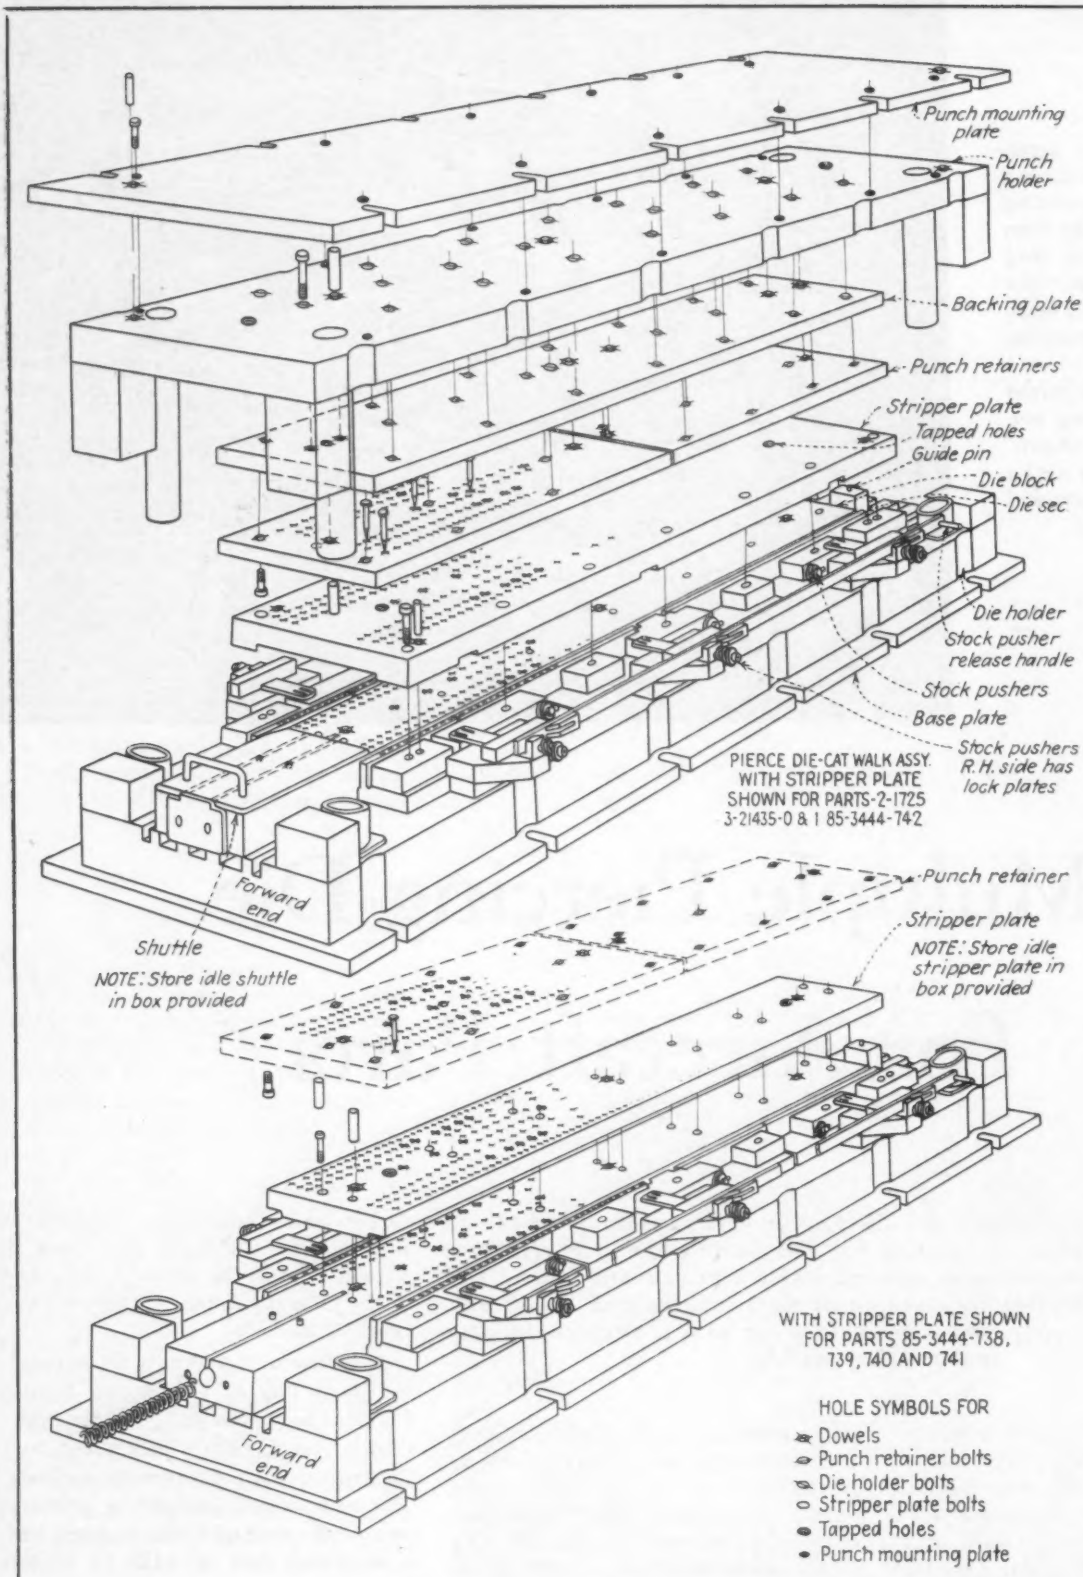
BELIEVED to contain a greater number of closely coordinated punches than any other piercing die ever constructed in aircraft work, the recently developed catwalk piercing die at the Boeing Aircraft Co., Seattle, incorporates 388 punches with a hole location accuracy of 0.0005 in. This unique die pierces a total of 976 rivet holes in the 10 separate parts which, when assembled, comprise the walkway through the bomb bay of the Boeing Flying Fortress. Production time insofar as the making of rivet holes is concerned, is improved 34 times over the old method by the utilizing of the press piercing methods. Because of the extremely close coordination of rivet holes, more rapid assembly is made possible, further increasing the overall usefulness of the die.

More important than the number of punches, however, is the diversity of this die on which 10 separate pieces are punched. These include two differently shaped and sized sheet stock parts, two pair of different angle sections and four extruded T-sections, all materials being 24ST aluminum alloy. Thicknesses vary from 0.064 to 0.150 in.

Flexibility in the use of the tool was made possible by a plan whereby stripper plates can be changed with comparative ease and little time. Aside from this, the only changes made in the die during the five different press operations required to turn out the 10 parts are found in adjustments to the stock pushers, and in the indexing points for the various types of material.

A redesign of the catwalk through the bomb bay of the Boeing Flying Fortress led to the design of the "porcupine," as this die is nicknamed, and the use of high production methods. The new design includes a primary web, or flooring of 0.064 in. dural and a secondary web of 0.125 in. alclad. The primary web receives the maximum 388 holes, while the secondary web gets 218 holes punched in it. The two reinforcement angles, both on upper and lower sides of the walkway are pierced with 51 holes each on the same stripper plate. The thickness of these parts is 0.150 in.

The second stripper plate is used to facilitate loading the four T-sections in the die. The forward extruded T-section receives 40 holes each, while the after two sections get 43. At the



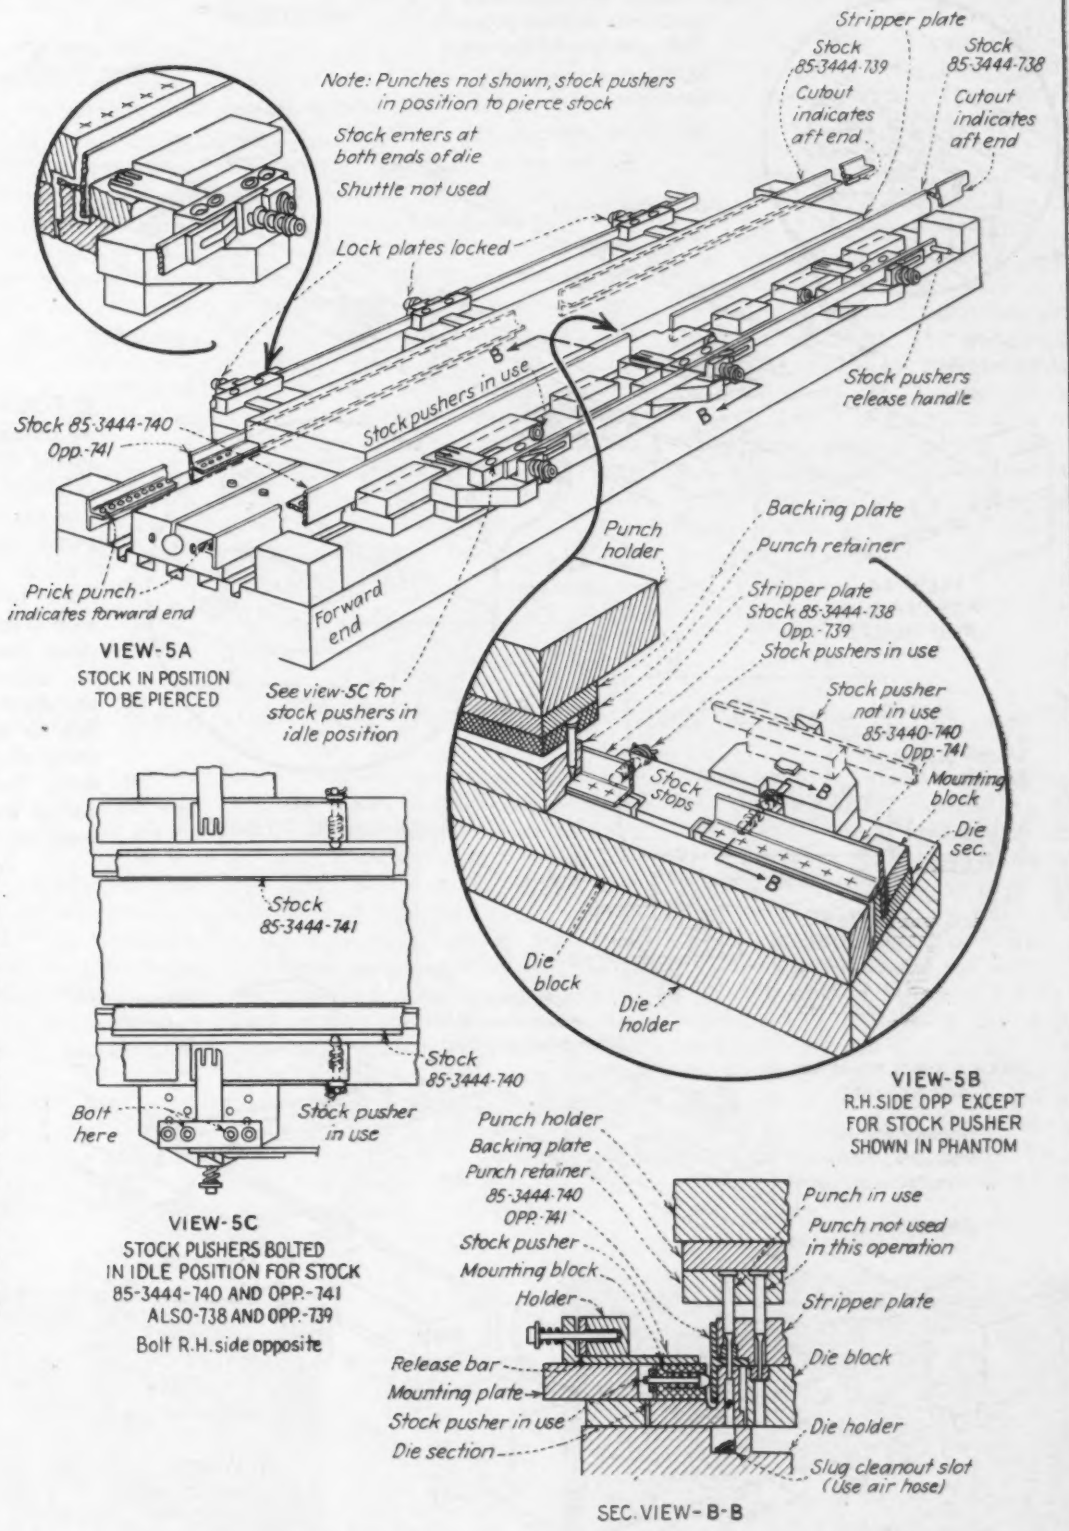
EXPLODED view multiple pierc die, shown set up piercing flat she Note the hand a ated shuttle stock e tor (left center) w provides a posi means of indexing well as rapid ejec of parts from the

point of piercing, these sections are 0.125 in. thick.

Absolute coordination of holes in all parts, both horizontally and symmetrically, was necessitated to make for ease and rapidity of assembly. Symmetrical coordination was of particular importance in that the walkway called for an upper and lower angle reinforcement on each side of the assembly. By piercing the upper right side angle on the lower left, and the upper left angle on the lower right side of the die, an extra stripper plate was avoided.

Use of Stock Pushers

Stock pushers incorporated in the die design provide for four different adjustments, one for each different press operation. This type of adjustment aids substantially in making the die sufficiently flexible to handle the variety of parts. The operation and setting of the stock pushers is explained to the press operator with the aid of production illustrations



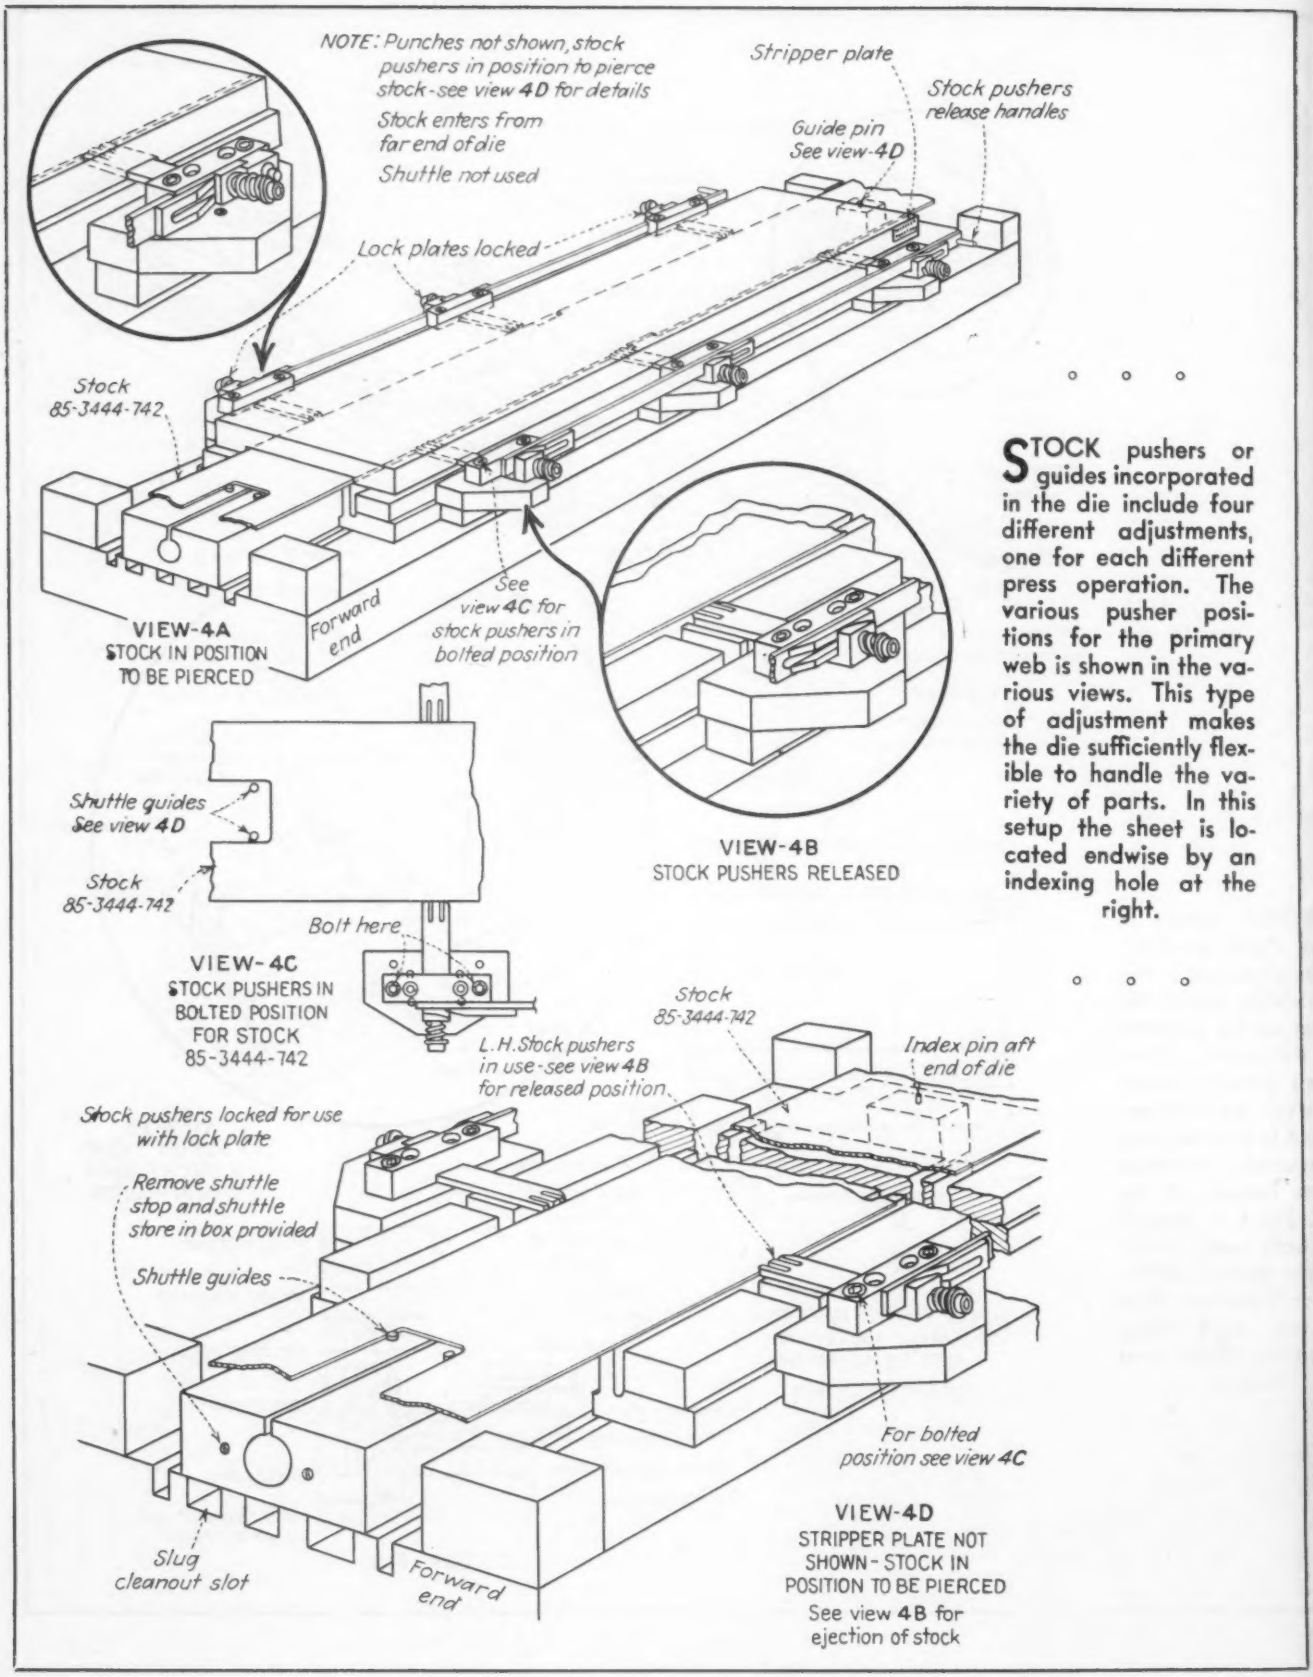
FURTHER details of the stock pushers can be observed in this view which shows the die set up for piercing four extruded T-sections simultaneously. The stock pushers are wedged in position and subsequently released by the handle at the right. Stock is loaded from both ends of die. Stripper plate is different for T-sections than the one used when punching flats and angles.

(see cuts) dealing with the operation of the die. These illustrations are turned over to the manufacturing shop simultaneously with the die.

The close coordination of holes called for a high degree of accuracy in die design as well as fabrication in a jig borer. The original design was projected in true perspective scale by production illustration, whereby mistakes in design and other flaws were caught on paper rather than in metal.

To facilitate ease of maintenance, the punches were mounted in two punch retainer plates. This simplifies the job of grinding the punches as well as replacement, which to date has been extremely low. Similarly, the guide pins were located on the punch rather than the die, to make possible the surface grinding of the die plate without necessitating the removal of the guide pins.

Another problem involved in the die design was the wide variety of gages specified for the redesigned walkway. In order to provide the proper punch



STOCK pushers or guides incorporated in the die include four different adjustments, one for each different press operation. The various pusher positions for the primary web is shown in the various views. This type of adjustment makes the die sufficiently flexible to handle the variety of parts. In this setup the sheet is located endwise by an indexing hole at the right.

clearance to minimize the possibility of flaring while punching and at the same time still produce a clean stripping action, the radial clearance between each punch and corresponding die hole was compromised, leaning slightly in favor of the heavier gages.

With D the punch diameter, and D the die diameter, the original problem was endeavoring to balance the two unequal equations:

$D + 0.005 = D_{10}$ for small punches.

$D + 0.015 = D_{10}$ for large punches.

That the final result was a satisfactory compromise is evidenced by the fact that cross-sectional photos of rivets driven through the series of holes show no unfilled sections, and that no punches have been broken because of improper stripping. Stripping action is aided by maintaining

the punch diameter slightly larger than the shank.

Because the only presses in the Boeing plant of sufficient size to accommodate this large pierce die are of the solid bed variety, five slug relief channels had to be provided under the die. This fact further complicated the problem of providing a sufficient amount of material in the die plate between the outer and secondary row of holes on either side and still provide the proper clearance for insertion of the angle stock, which was to be pierced by the secondary row of punches. Working to close tolerances and proper prepositioning of stock, precision workmanship fulfilled the design at these critical points, where the 0.167 in. holes are ½ in. apart on centerline, leaving a relatively small amount of material in the die "rail" section. At the thinnest section it is 0.186 in.

The indexing of the different parts is accomplished by a variety of methods. The secondary web and the reinforcement angles are controlled by the shuttle stock ejector. This makes a positive method of indexing, as well as a rapid means of ejecting parts from the die. The T-sections are indexed against a stock stop block installed during the changing of the stripper plate which is used for this piercing operation. The primary web is located in the die by an indexing hole. The reason for not indexing this part on the cutout shown (in the lower left corner of view 4-C) is that this removal of stock is accomplished on a router, which does not make a sufficiently accurate cut for locating purposes.

It is interesting to note that no master gage or template was used in making the die. The system of all hole location is a dimensional layout on which each hole is accurately located in respect to X and Y coordinates, making possible the reproduction of any part of the die by drilling all holes on a jig borer. Thus costly master tools were eliminated. The inspection of production parts was also simplified by the die. The aircraft inspection of production parts was also simplified by the die. The aircraft inspector checks the die when it is set in a press to make certain it has not been damaged and to verify that the die bears the stamp of a Boeing tool inspector, signifying that the punches are sharp and properly positioned.

Wire Bending Attachment on Spot Welder

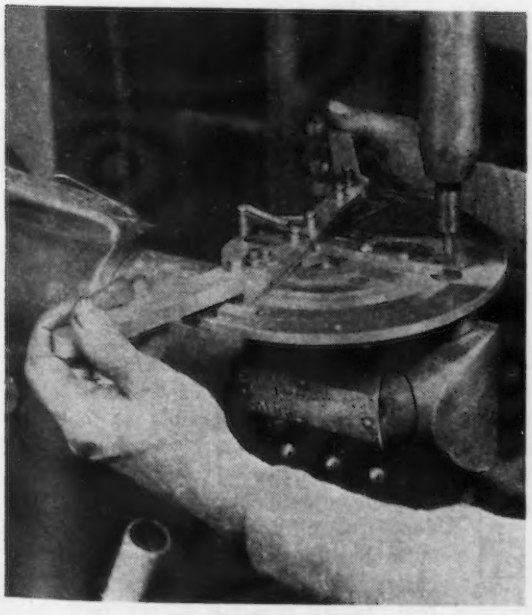
THOUSANDS of hours spent in the manufacture of small hose straps used in Boeing Flying Fortresses have been saved by the use of a simple bending attachment on a spot welder. The device was designed and produced by the tool design department of the Boeing Aircraft Co. in Seattle and has resulted in two workers producing as many straps in 1 hr. as six persons did previously in a full day.

The strap, or tube lock, used to secure hose and tubes installed in Fortresses is bent from a piece of stainless steel wire into an oval shape about 3 in. long and then the free ends are welded together. Previously the wire was cut in one shop, formed in a second and flash welded in a third. Because cutting left the ends too irregular for flash welding, they had to be ground until they met each other squarely. Despite the extra process of grinding, rejections on inspection were running about 5 per cent because of faulty welds.

Leon Mooradian, assistant chief research engineer, and his associates decided that spot welding would be more satisfactory than flash welding. The problem was how to form and spot weld the straps with a minimum of effort and time.

The answer finally evolved itself into the attachment illustrated. Attached to the spot welder arm, the fixture holds a die around which the wire is bent into the form of the strap by two hand levers which join the ends in position for welding. A foot lever then operates the welder.

Wire is still cut to length before it is inserted in the bending die, as the production did not warrant use of an automatic cutting device on the attachment. Neither did it warrant automatic bending of the wire, so the device is operated by hand. There have been no rejections since the fixture has been in use.



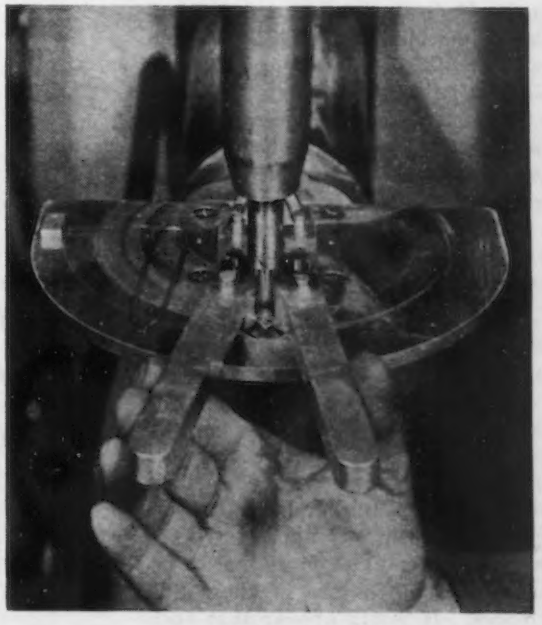
LEFT

THE stainless steel wire stock is located in the fixture by using as a guide the end locator on the left of the semicircular plate. The rear end of the forming block acts as a front locator. The operator then pulls on the forming arms of the fixture, causing the wire to bend to the contour of the form block.

o o o

RIGHT

THE forming arms have a slight tip which causes the wire ends to cross directly over the lower welding electrode. The weld is then made.



Cold-Blast Irons Duplicated

By J. E. HURST, D. Met.
Lichfield-Staffs, England

o o o

THE fact that the properties and behavior of pig irons frequently vary in a manner which cannot be predicted from the knowledge of the chemical composition, or even the fractures, is quite well known. Numerous examples of incidents confirming this have been reported by reliable observers over a long period of years.

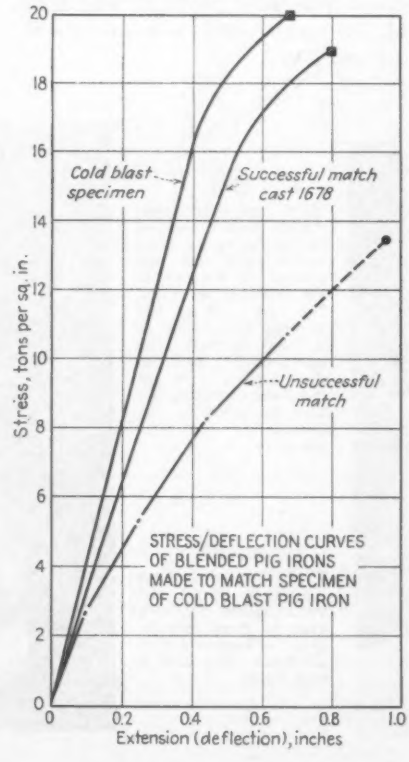
Perhaps the outstanding examples of difference in properties and behavior for irons of similar composition are to be found in comparison of the properties of cold-blast and charcoal pig irons with pig irons made by other methods. These differences in properties and behavior are still utilized in the section of the iron founding industry devoted to the production of cast iron rolls where pig irons produced in cold-blast furnaces are still used on account of their desirable properties. The high cost of true cold-blast irons has frequently operated as an incentive to endeavor to produce pig irons by cheaper methods which would still possess those properties of cold-blast irons, frequently described as intrinsic properties.

There are quite a number of recorded attempts to this direction, and as an example it is possible to quote the work of the late J. E. Johnson, Jr., in the U. S. A., whose investigations culminated finally in a British patent for a method of duplicating cold-blast pig iron from hot-blast pig iron. The method consisted of blowing oxygen gas through molten hot-blast pig iron and was based principally on the observation that metal so treated yielded a structure under the microscope possessing characteristics similar to cold-blast iron specimens examined.

There are plenty of references in the technical literature of the world to these experiences of differences in behavior and methods of making hot-blast irons equal to irons produced by cold-blast furnaces. References were given to some of these in THE IRON AGE, July 1, 1943, by Ralph H. Sweetser. There does not appear to have been any attempt to investigate systematically the nature of these differences. It would appear that such an investigation should precede any attempt to formulate methods of duplicating the properties.

For a number of years now the writer has given some attention to this matter in the research laboratories under his control, and as a starting point endeavored to summarize the differences in properties claimed for cold-blast irons by those who had had considerable experience of their use. Inquiries revealed general agreement that cold-blast irons had differences in the various attributes of their strength properties, and also differences in the chief characteristics obtained when casting either chill test pieces or actual chilled rolls.

FIG. 1 — Stress-deflection curves of blended pig irons made to match cold-blast pig iron.



The views on the strength properties may all be summed up fairly in the statement that cold-blast irons are tougher than other irons. The chill characteristics are described by references to the depth of chill and its hardness; the depth of mottled portion following the chill; the type of chill which is described in terms of brightness and utilizes such descriptions as bright, dull, medium bright, normal, etc.; and the type of general fracture following the chill and mottle which is described in terms of closeness, openness and grayness. It is unnecessary almost to state that the comparisons of these chill characteristics are made upon test specimens cast under controlled conditions of size and chill surface, and are considered in relation to the chemical composition of the specimens. While to the experienced eye these chill characteristics are readily distinguishable, none of them, with the exception of the depth and hardness values, is capable of being expressed in numerical quantities, and this, of course, makes investigation somewhat difficult. There are, of course, several ways of overcoming difficulties of this type.

In a like manner, in the case of toughness, little enough evidence of a quantitative character is available, and this state of affairs is due probably to the fact that the measurements of the "toughness attribute" of the strength properties of cast irons has not been practiced in testing laboratories, most workers being generally satisfied with the simple determination of the ultimate breaking strength, which, of course, is not necessarily related to the toughness.

Further discussion of these problems with experienced users of cold-blast pig irons revealed the fact that it is frequently possible to obtain other types of irons possessing some of the properties. For example, it is possible to duplicate the hardness and depth of chill quite frequently by suitable manipulation of the chemical composition, but it appears to have been rarely possible in the past to

by Synthetic Mixtures . . .

. . . Differences between the characteristics and properties of cold-blast pig irons and other types of pig irons have been observed and experimentally investigated. The results are reported by the well-known English metallurgist herein. These results in part answer the question propounded by Sweetser in "What is the 'It' in Charcoal Pig Iron." The Iron Age, July 1, 1943.

duplicate all the properties in the same brand of pig iron.

Good Resilience Values

It was considered that any investigation work undertaken with the object of attempting to duplicate the properties of cold-blast irons should be concerned in the first place with determining the quantitative value of the differences in the various attributes of the strength properties. With this end in view, a large number of specimens have been examined for modulus of elasticity, resilience value, limit of proportionality, permanent set, internal stress, elastic hysteresis, in addition to the ultimate breaking strength or modulus of rupture. These tests confirmed the observation that cold-blast irons showed differences in properties. The details of these tests are to be found in the Foundry Trade Journal, February, 1935. Here the properties of a series of specimens taken from reputable brands of cold-blast irons are compared with those of an ordinary refined iron. Special attention is directed to the marked difference in the resilience value in addition to the differences in ultimate breaking strength.

These investigations were followed up by the examination of the same properties in a variety of pig irons prepared by the various methods in common use and derived from different districts and countries. A large number of these results were published by the author in a paper, reference to which will show widely differing properties. (Manchester Association of Engineers.) Eventually it was decided that this might form the basis of additional scientific blending methods with the object of duplicating exactly the properties of a given type of pig iron. Following this decision, the chemical analyses of pig iron supplies have been reinforced by the complete mechanical analysis in which the properties as above mentioned are determined. In order to match the specific properties of a given type of cold-blast pig iron the procedure followed is first to determine the chemical analysis and the complete mechanical properties of the particular brand or consignment of iron required to be matched. With this information available, a mixture is devised from the various materials in stock of which the chemical analyses and mechanical properties have been determined. The mixture is calculated to give a mean chemical and mechanical analysis closely approximating that of the sample desired to duplicate. The success of this procedure relies on the assumption that the differences in properties of the mixed materials survive remelting, and this assumption has been submitted to experimental verification.

This experimental work demonstrates clearly that the intrinsic properties of cold-blast irons can be matched both in mechanical properties and chill characteristics by this method. The actual details of the methods adopted in matching the exact properties of different pig irons can be followed from the description of the experimental procedure followed in matching a well known brand of cold-blast iron from a sample submitted. The sample received was in the form of a half pig and the chemical analysis taken on drillings from the face of the pig in the manner recommended in the B.C.I.R.A. sampling methods gave the results shown in Table I.

FIG. 2—Elastic hysteresis of blended and cold-blast pig irons.

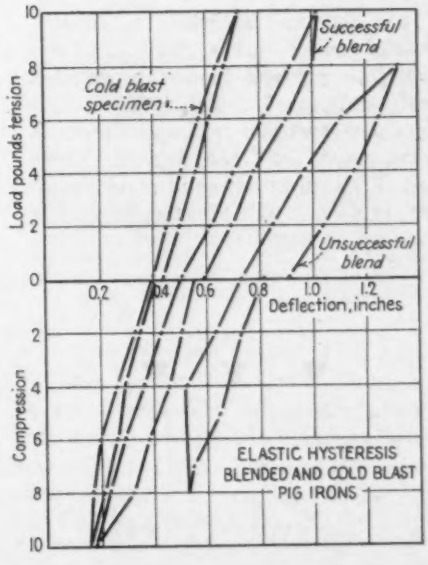


TABLE I

Analysis of Sample and of Test Specimen

	Original Iron, Per Cent	As Remelted for Test Specimen, Per Cent
Total carbon	3.55	3.40
Silicon	1.83	1.82
Manganese	0.87	0.74
Sulphur	0.050	....
Phosphorus	0.48	0.47
Nickel	Nil	....
Chromium	0.050	....

The supplier confirmed that the rather unusual silicon and manganese contents revealed by this analysis were representative of the normal quality of this iron as purchased by them. For the determination of the various attributes of the strength properties a portion of the specimen was remelted in a Morgan oil-fired crucible furnace using a clean new standard Morgan Salamander crucible. The metal was heated to a temperature of 1495 deg. C. (2723 deg. F.), as recorded by means of a Foster optical pyrometer, and test pieces were cast from this temperature into the form of the standard "Star" test bar molded in oil-sand molds standing at a temperature of 85 deg. C (185 deg. F.), measured by a mercury thermometer inserted down the ingate of the mold. The fins of the "Star" bar when broken showed very slight chill, not more than 1/16 in. at the

extreme edges and standard test rings were machined from the cylindrical barrel of the test bar. These rings were used for the determination of the following properties: (1) Internal stress value; (2) modulus of elasticity (end value); (3) modulus of rupture (tensile strength); (4) stress deflection curves; (5) resilience value; (6) permanent set value; (7) elastic hysteresis curve; and (8) Brinell hardness (Firth Hardometer 2-mm. ball, 30-kg. load).

Results Obtained

The ring tests and stress calculations were made in accordance with the methods laid down in B.S.I. Specification No. 5004. Chemical analyses were made of the remelted specimens with the object of ascertaining the magnitude of any changes which may have taken place in remelting. The results are given for comparison alongside those of the original specimen, and the only change of any magnitude to be noted is the reduction in total carbon and manganese contents. The mechanical-test results obtained are summarized in Table II.

In the case of some of the determinations three separate tests were made, in which case the average of the three determinations has been recorded in Table II. The stress-deflection curve and the elastic hysteresis curve are illustrated in Figs. 1 and 2. In general, the results obtained are typical of good cold-blast irons. The resilience value is somewhat lower than the results obtained from previous examinations of this same brand of iron, and this may be due possibly to the fact that the silicon and manganese contents are higher in this than in previous specimens examined. The fracture of this specimen prior to remelting was described as a fairly close No. 3.

With these test results available, a mixture was calculated utilizing pig irons of known mechanical properties in addition to the chemical compositions. The mechanical properties of the pig irons used were determined on rings machined from "Star" bars cast from remelted specimens of the irons, following the method exactly as above outlined. The mixture as calculated was remelted and cast into pig form, and a specimen of pig taken for the determination of the properties. Here again the same procedure of remelting and casting a "Star" test-bar was followed.

The test results of two mixtures calculated to duplicate the properties of the specimen submitted are included. The first attempt did not provide a satisfactory duplication and these results are included as further evidence to show that, although the chemical composition was matched quite closely, the mechanical properties may differ quite substantially. The second attempt from a modified mixture, Cast 1648 (Table III), gave a very satisfactory duplication of the properties of the specimen submitted, as will be seen from an inspection of the test results in column 2, Table II, and the stress-deflection curves and elastic-hysteresis curves in Figs. 1 and 2.

TABLE II

Properties of Cold-Blast and Synthetic Irons

	(1) Cold Blast Specimen Submitted for Matching	(2) Blended Iron, First Attempt	(3) Blended Iron, Cast 1648 Successful
Tensile strength, tons per sq. in. (ring test)	20.6	16.5	21.2
Resilience value	20.6	14.4	19.8
Permanent set value	12.5	30.6	10.9
Internal stress value	+ 0.003	+ 0.004	+ 0.005
Modulus of elasticity (end value)	18.7	13.5	17.9
Brinell hardness	215	207	207

TABLE III

Chemical Analysis of Specimens Cast 1648 Exactly Duplicating the Cold-Blast Pig Iron (Table II, Column 3)

	Pig Iron, Per Cent	Remelted Specimen, Per Cent
Total carbon	3.70	3.42
Silicon	1.95	1.90
Manganese	0.95	0.88
Sulphur	0.029	....
Phosphorus	0.51	0.50
Nickel	Nil	....
Chromium	0.026	....

The chemical analysis of the successful match taken from drillings from the pig and from the remelted test-bar is given in Table IV. In this case the test-bar was cast from a temperature of 1480 deg. C. (2696 deg. F.) into an oil sand mold standing at 81 deg. C. (178 deg. F.). The fracture of this pig iron was described as a scattered No. 4.

The results in column 2 of the table and the stress-deflection and elastic-hysteresis curves in Fig. 2 show quite substantial differences from the required values, even although the chemical compositions of the specimens are quite close to those required, as will be seen from the results shown in Table IV.

TABLE IV

Chemical Analysis of Specimens, Column 3, Table II

	Pig Iron, Per Cent	Remelted Specimen, Per Cent
Total carbon	3.62	3.49
Silicon	1.96	1.92
Manganese	0.90	0.79
Sulphur	0.042	....
Phosphorus	0.50	0.49
Nickel	Nil	....
Chromium	0.031	....

Summary

Differences between the characteristics and properties of cold-blast pig irons and other types of pig iron have been observed and experimentally investigated. It has been shown that the chemical composition, fracture and mechanical properties of cold-blast pig irons can be very closely duplicated in all their characteristics by synthetic mixtures, and that irons which so duplicate these properties in entirety also duplicate the properties of chilling characteristics. Thus, it has been shown experimentally that the whole of the known characteristics of cold-blast irons can be completely duplicated. These results in part at any rate provide an answer to the question propounded by Sweetser "What is the 'it' in Charcoal Pig Iron."

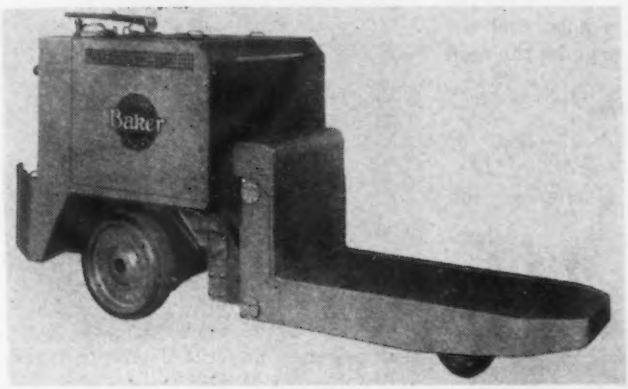
New Equipment . . .

Material Handling

Some of the more recent developments in conveying equipment, cranes, electric trucks, carriers and other material handling apparatus are described and illustrated in the following pages.

THE Baker Industrial Truck Div. of the *Baker-Raulang Co.*, 2168 West 25th Street, Cleveland, announces a 4000 lb. capacity type E-2 low-lift truck. The alloy-steel trailing axle is firmly anchored to the frame



and the wheels steer on anti-friction bearings. The duplex compensating suspension eliminates all sliding contacts between the power axle and frame and an improved hydraulic lift system provides positive control of hoisting and lowering. The company has also developed a 3-ton Hy-lift truck, Type H-3, which may be used for both transporting and tiering skidded material.

Bar Stock Truck

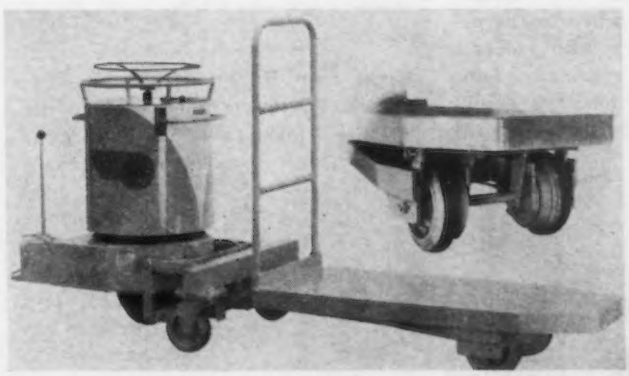
A TRUCK for handling bar stock has been announced by *Rose Mfg. Co.*, 12400 Strathmoor, Detroit. A balanced, four wheel type, it can be turned around in its own length like a turntable. It is furnished with two heavy duty swivel casters front and rear and heavy duty steel wheels, equipped with Hyatt roller bearings. A trailer coupling is on the front.

Wood Pallets

TWO types of wood pallets with steel reinforcement have been brought out by *Palmer-Shile Co.*, 784 South Harrington Avenue, Detroit. They are designed for use with either power or hand fork trucks. Both are of hardwood construction with replaceable obard. The single face model has metal bound ends with strong metal supports. The double face model is completely steel armored.

Turret Truck

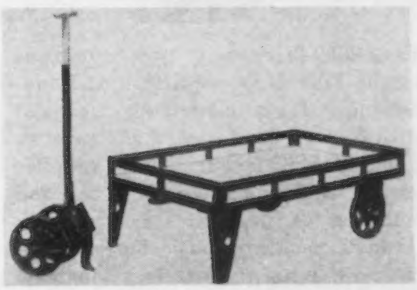
SEVEN new features have been added to the Salsbury lift type turret truck distributed by *Nutting Truck & Caster Co.*, Faribault, Minn. The hand-operated hydraulic lift lever is at the right of the driver's platform. At the left is the load-wheel brake pedal which actuates internal



expanding brakes on the two load wheels. The primary drive chain is fully enclosed. The lift platform has been tapered to permit oblique angle entrances to skids. This model is one of three, the other two models being platform and tractor types.

Wooden Deck Transport

A MODIFICATION of their wooden deck transport has been brought out by *Factory Service Co.*,



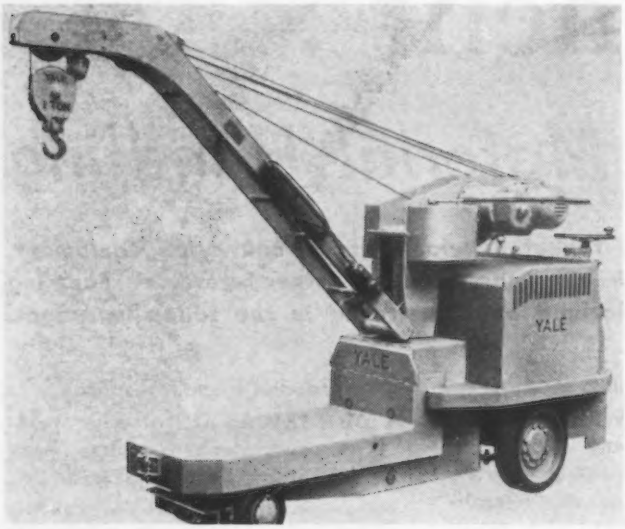
4615 N. 21st Street, Milwaukee, which can be moved in restricted spaces by means of a hand jimmy, power lift truck, crane, tractor or conveyor. A 4-in. railing is welded to the transport for retaining various size containers to be taken to departments for servicing machines. The transport is a unit of the Turner shop system.

Rolling Die Table

THE Multiduty die table put on the market by the *Barrett-Cravens Co.*, 3256 West 30th Street, Chicago, serves as a portable work bench, a die set separator and a lifting table for storing, moving and setting up dies, for supporting bars and sheets of steel for milling and for other jobs performed by lifting tables. Two models are offered. Style B-1 handles dies up to 40 in. long and has a table capacity of 3000 lb. Style B-2 will take dies up to 32 in. long with a table load of 2000 lb. Both models can be equipped with wheel brakes.

Two Unit Crane Truck

THE Model K23E-6C2T, 6000-lb. capacity low elevating platform truck has been combined with a Cable



King 2000-lb. capacity twin unit crane by the *Yale & Towne Mfg. Co.*, Philadelphia. It is electrically powered with four speeds forward and reverse. The Cable King winch unit supplies the hoisting and booming power and both can be operated simultaneously through separate push button type crane and hoist controls. Separate, independent motors and power units drive the truck for travel as well as hoist and boom the load.

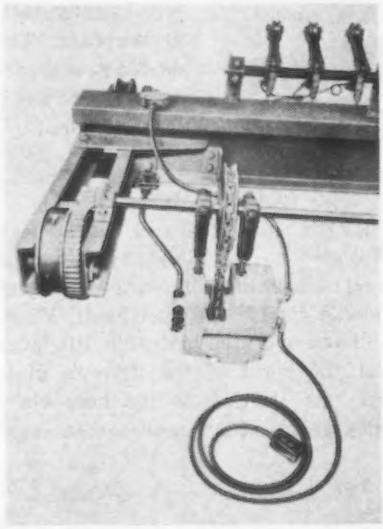
Backrest Extension for Lift Truck

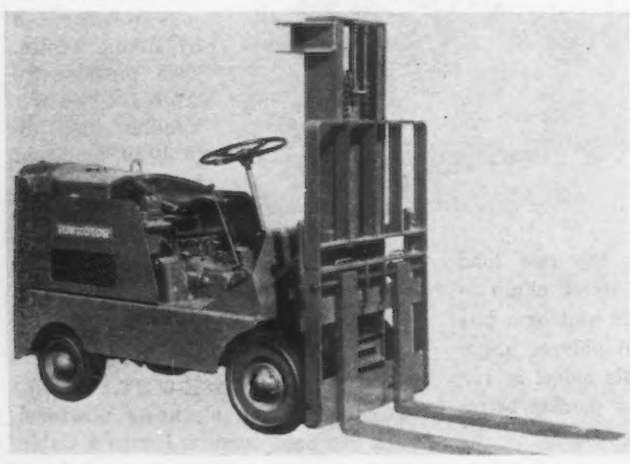
TO facilitate handling higher stacks of case goods, bags, drums, bales or other small-unit bulky loads which normally would extend above the tops of lifting carriage backrests on standard lift trucks, *Towmotor Corp.*, 1226 East 152nd Street, Cleveland, has developed a carriage backrest extension which provides increased support and minimizes the possibility of shifting while high loads are being lifted, moved and stacked. Pins permanently attached to the extension are inserted into sockets welded to the lifting carriage. Thus held securely in position, the extension increases the support area afforded by the lifting carriage's standard backrest and makes it practical to handle multi-unit loads of much greater height with normal stability and safety. Models which increase carriage backrest height from 48 to 72 in. above forks are available.

The company has also developed a drop bottom dump skid box which is unloaded by hooking the back of the box to the hoist and the lowering of the forks permits the load to skid out.

Crane Drive

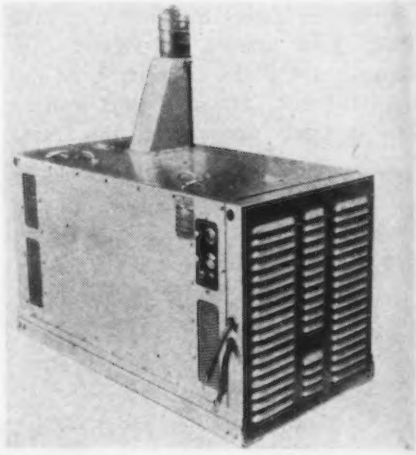
THE *Budgit Products Div. of Manning, Maxwell & Moore, Inc.*, Muskegon, Mich., is placing on the market the Budgit Bridge Drive, a complete, self-contained unit to convert the bridge travel motion of hand-operated cranes to electric drive. The only tool required to install it on a crane is a wrench. It is suitable to convert hand-operated cranes of either the single or double girder type of 10 tons or smaller capacity, provided the crane is of the geared type and operated by a chain wheel of 24 in. or smaller diameter.





Gas-electric Power Unit

THE heavy-duty Model J gas-electric power unit has been designed for 10 to 30-ton electrical industrial trucks by *Ready-Power Co.*, 3828 Grand River & Avery Street, Detroit. The unit consists of a gasoline engine closely coupled to a direct current generator complete with all accessories mounted in a steel housing for fastening to the truck chassis. Electric power is generated on the truck and delivered to the motors through standard electric truck control mechanism. Several sizes are manufactured for trucks of from 1 to 30 ton capacity.



Tractor Crane

A HYRAULICALLY operated and steered tractor crane is announced by *Hi-Way Service Corp.*, 3841 West Wisconsin Avenue, Milwaukee 8. Known as the Drott Go-Devil, the unit has a positive hydraulic up and down power that enables the boom to handle loads weighing up to 2000 lb. Outriggers prevent it from tipping over. All controls are within easy reach of the operator. The boom swings a full 360 deg., has an extension to 90 in. and reaches to a height

of 14 ft. 2 in. There is a 10½ ft. turning radius and traveling speeds up to seven miles per hr.

Stacking Box

A LIGHT weight shop box has been brought out by the *American Metal Works, Inc.*, 1517 Germantown

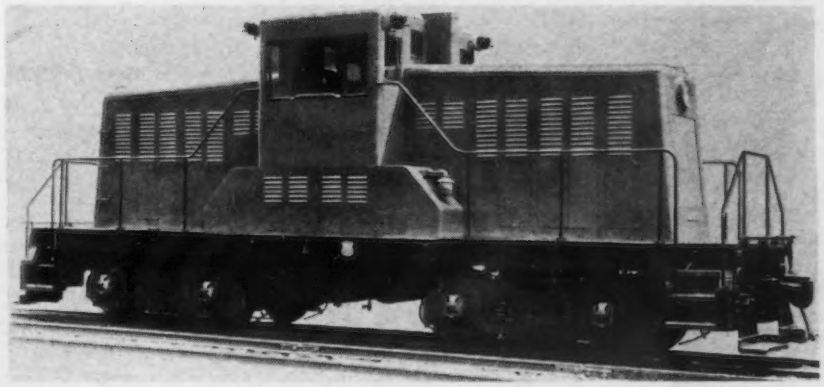
Avenue, Philadelphia 22. The open front makes contents accessible when boxes are stacked and label above opening permits easy identification. The finish is olive green enamel.

Crane Controller

A CONTROLLER for the operation of electric cranes on a.c. current has been developed by *Cutler-Hammer, Inc.*, 315 North 12th Street, Milwaukee. Direct current generating equipment or rectifiers need not be installed. The new control provides dynamic lowering over five stable speed points; accurate inching for spotting loads and timed acceleration in both directions from a standard 5-speed master switch.

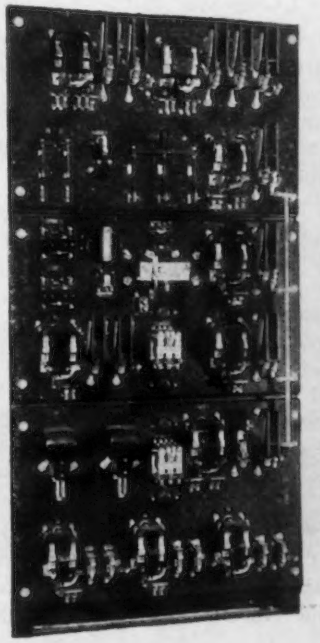
Electric Locomotive

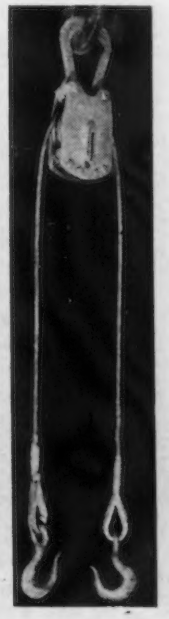
MANUFACTURE of 100-ton diesel electric switching engines with double power plants has been announced by *H. K. Porter Co., Inc.*, 48th and Harrison Streets, Pittsburgh. The locomotive can be used efficiently with only one engine operating. With half a load it can travel as fast with one engine as the two engines can travel with a full load. The single operating station is mounted high, giving superior visibility. Large safety platforms on each corner of the locomotive are provided for ground men.



Wire Rope Sling

A WIRE rope sling which will equalize itself automatically and lift a load level has been developed by *MacWhyte Co.*, Kenosha, Wis. Called the Caldwell "Level-Lift," the rope operates through a block mounted on the crane hook. The equalization feature consists of a floating sheave or drum having a braking action to arrest leg adjustment after the load is lifted. The crane is spotted over the approximate center of gravity of the load and as the power is applied, the legs of the sling automatically adjust themselves to the lengths necessary to lift the load level. The sling will handle loads up to 3 tons. Capacity of two units used together is 6 tons, figuring a safety factor of five.





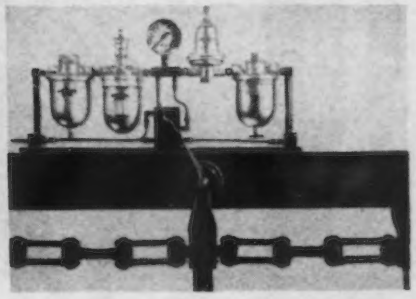
Hydraulic Elevating Table

LYON-RAYMOND CORP., 1235 Madison Street, Greene, N. Y., has put on the market an improved hydraulic elevating table for use in handling dies, locating work for welding, transferring heavy parts from one level to another, supporting over-

hanging work, bringing work to convenient heights for the operator or operations where easy foot-actuated elevation is advantageous. The unit is made with two stationary and two swivel casters, but it may be locked in one position.

Trolley Lubricator

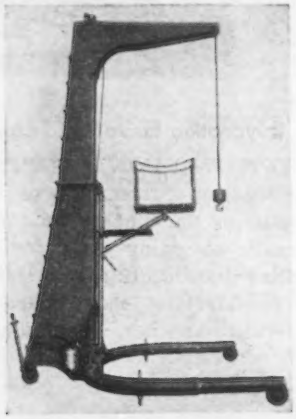
A TROLLEY lubricator which automatically lubricates each wheel bearing with oil saturated air has been developed by the *Bjerre Co.*, 1253 West Fulton St., Chicago. The jets follow the wheels, insuring positive



lubrication. The oil feed, air pressure and trigger contact are fully adjustable. One solid block contains all working parts of trigger mechanism.

Overhead Portable Crane

A PORTABLE hydraulic overhead hoist has been put on the market by *Federal Aircraft Works*, 3456 North Mississippi Drive, Minneapolis. Model PH-4002 has heavy duty ca-



pacity with a wide factor of safety; compactness with high range of lift and clear working area underneath the hook as well as around the entire structure; and ease of portability in and about crowded working areas. A beam lowering mechanism and quick attachment towing dollies are available as optional features.

Lightweight Hoist

A LIGHTWEIGHT cable hoist, the Cablemaster, developed by the *Master Electric Co.*, 126 Davis Avenue, Dayton 1, is equipped with hook

or trolley mounting and may be attached to monorail mounting or to special 4-ft. jib crane. The unit may be installed at each machine tool or bench, eliminating waiting for general overhead hoist. Three sizes are available in 250, 500 and 1000 lb. capacities.

Crane Stability Gage

WHEN a huge boom crane lifts a heavy sub-assembly for a warship in a shipyard, the weight may overturn the whole crane. To eliminate such danger, *General Electric Co.*, Schenectady, has developed a crane

stability gage which gives the operator a continuous picture of his margin of safety and automatically stops the crane if it takes on too heavy a load or if the boom moves too far out.

Improved Conveyor Belt

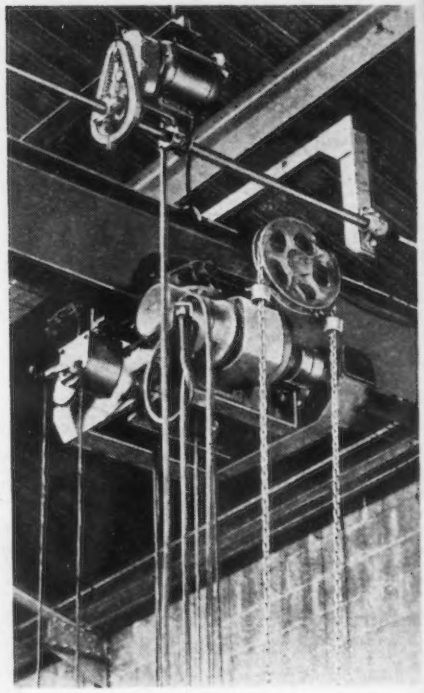
A PATENT has been granted on its Transcord breaker, used in constructing conveyor belting, it is announced by the *B. F. Goodrich Co.*, Akron. The breaker cords are placed across the belt width, rather than parallel with the cords of the belt itself, which provides much greater adhesion between cover and carcass than regular breaker construction. The construction tends to stop most cuts and gouges before they penetrate to the belt carcass. The breaker is usually placed a short distance above the top ply, leaving a protective layer of rubber between breaker and carcass.

Magnetic Separator

A MAGNETIC separator designed to operate on the principle of the Ball-Norton underfeed lift method has been built by *Stearns Magnetic Mfg. Co.*, 260 South 29th Street, Milwaukee. In this Type M, a patented magnetic field is mounted above the lower surface of the separating belt. The mixed material is distributed in an even layer by an automatic feeder to the feeder belt which carries the ore or other material into the magnetic field where the magnetic portion is lifted by the power of the magnet to the surface of the separating belt. The company has also announced complete line of round lifting magnets to supplement its magnetic separators, suspended magnets and rectangular lifting magnets. Sizes range from 20 to 65 in. with corresponding weights of 450 to 8900 lb.

Motor Crane Drive

TO make a motor-traveled crane out of a hand-traveled crane without requiring any structural changes, the Travelator has been de-



veloped by the *Northern Engineering Works*, Atwater at Chene, Detroit. The unit is mounted on a channel iron in such a way that it drives the squaring shaft through a split sprocket. This is mounted on a split clamp, so the assembly is applied without removing the squaring shaft. The only part of the crane removed is the hand pull chain. Control is through the pendant cord push button, which may be arranged to follow the trolley. The unit may be mounted at any position on the squaring shaft and the motor may be placed at any angle.

11. Obtain automatic torque control?
12. Obtain accurately matched speed of various rotating elements?
13. Obtain constant speed output from a variable speed input?
14. Obtain full pre-set automatic control, elimination of problems of shock, vibration, etc.?

You Need Oilgear!

OILGEAR

An Oilgear Plus: Oilgear also enabled Neo Gravure to discover for the first time the correct pressure to use on their impression cylinders. Result: longer sustained quality, longer roller and cylinder life.

The Famed Oilgear *"Glide"* May Solve a Drive Problem for You

To print an entire magazine in 4 colors, on both sides of the paper, in one pass through a huge rotary press requires an unbelievable miracle of smoothness and synchronization. But the Neo Gravure Printing Company of New York and Chicago weren't getting the miracle. They got spoilage, waste and delay instead. So they turned, as many another company or machine designer in trouble has turned, to Oilgear Fluid Power. That was in 1934, then 1936, then 1937 and 1939. For they found that Oilgear accelerated their presses as "smooth as silk" from zero speed to maximum . . . synchronized all press units in lock-step . . . gave a new precision control, hundreds of feet more floor space, and a performance which became a new standard for the industry.

The famed Oilgear stepless acceleration is just one of the dozens of remarkable functions this remarkable system can bring to your machine design problem. Maybe you want tremendous power in small space . . . power around corners where belts and gears can't reach . . . a combination of rotary and linear motion. Maybe you need something you haven't thought of. Why don't you consult Oilgear engineers' broad experience and see what Oilgear versatility can do. Now is the time to write. . . . THE OILGEAR COMPANY, 1303 West Bruce Street, Milwaukee 4, Wisconsin.

Fluid Power

Assembly Line . . . STANLEY H. BRAMS

• Auto parts companies look on aviation work as important share of postwar activity . . . Thompson's Crawford calls for humanized relations with labor . . . Detroit craft wages stabilized.

DETROIT—Last week's general meeting of the members of the Automotive and Aviation Parts Manufacturers, Inc., formerly the Auto Parts and Equipment Manufacturers Association, was notable for two reasons. As the first meeting in three years, it indicated aptly that the supplier companies feel the necessity of brushing up once more on their functioning in a civilian economy. Second, there was a notable address by Frederick C. Crawford, director of the association, and president of Thompson Products Co.

The change of name of the supplier group is backed up by some interesting statistics. A questionnaire circulated among members established that approximately 70 per cent of the companies are in aviation work today, against about 36 per cent before the war. Of the total membership canvassed, 62 per cent expect to be in aviation work after the war, approximately double the number in this field before the war. By and large this group comprises a good cross-section of the parts manufacturing industry, large and small plants alike.

Few of them indicate they expect aviation work to be a major factor in their operations through the medium term after peace, the general outlook being that aircraft production planning is a long-range proposition. As evidence of this, only 3 per cent of the companies expect postwar aviation work to be of first importance, 33 per cent of all those canvassed rate it as of second importance, and the same proportion assign it to third position. The balance do not expect to be in the field, or did not indicate the order of importance they attach to it.

Mr. Crawford, repeating an address he made in a closed meeting in the east some time ago, declared that management largely has fallen down on one of the most important phases of its job—acquainting its workers with the advantages of a capitalistic system built on a profit incentive. Comparatively few of the people living under this system in this country understand how it works, and if they are not taught to understand, Mr. Crawford maintained, capitalism is likely to fail.

Management by and large, he said, fails utterly to sell the capitalistic system to the workers in their plants. As a means of doing so he touched on the 15-year program in labor relations which has been carried on by Thompson Products Co. in its Cleveland plant. Essentially, the program is built around a plan of humanized labor relations, developed from the philosophy that a worker, as a typical American, is susceptible to emotional appeal, whether good or bad, and that simple common sense therefore calls for inculcating him with a sound emotional approach before he can sold an unsound one. Otherwise stated, good management leadership is looked upon by the Thompson people as an antidote to bad political and bad labor leadership. "The worker wants information," said Mr. Crawford. "He is confused today. He has no conception how industry creates wealth and a higher standard of living."

A SURVEY recently made by the company tended to confirm this viewpoint. Questionnaires were distributed to all employees, for anonymous answer, allowing free play of expression. Most answers dealing with good labor relationships stressed their human side, giving surprisingly little thought to pay or hours. Hardly an individual worker who answered the question saw the relationship of political rules and governmental controls to his job. Notable was the complete lack of comprehension of the effect of taxes, investment-hobbling legislation, federal labor policy and other basic ground rules of industrial operation today.

"Broadly, there is little evidence that the workers have any idea of the American productive process," Mr. Crawford emphasized again and again. Thompson Products has finished up its studies of this survey with one thought uppermost in its mind: The average worker, a good American, must understand why he works. On this understanding or lack of it, believe Thompson executives, may stand or fall the future of America.

THIS is a viewpoint worth thinking about. There is much smug and selfish and short-sighted management in America today, perhaps not as much as there is selfishness and short-sightedness in labor and in government, but enough so that the framework of blame has an approximation of a third leg to stand on. There is much food for thought in Mr. Thompson's remark that management pays the worker and has him under influence eight hours a day, while a labor leader takes money from the worker and holds him for but 10 minutes a day—that the advantage is quite obviously management's, yet management does not utilize it except in scattered plants like Thompson.

There may not be a world revolution going on in these times, but there is certainly a changed state of affairs. The Russian revolution may have started it; the labor governments of Britain were signs the chaotic overextension of the development in France caused that nation's downfall; and the rise of the labor movement in this country is another indicator. The social condition of the times is a factor in our national life today; it has been, and it likely will continue to be. Wise managements, like Thompson, will not make a futile effort to beat back the tide, but will learn instead how to swim with it. Only in selling the motives of the boss and the company to the worker will the capitalistic system be able to justify itself in the minds of the hourly-paid men who, startling as this statement may be, benefit the most from it.

Signs crop up here and there of a humanized approach to worker problems. One Chrysler unit, the Evansville Ordnance Plant, made a move recently which might be worth consideration by other firms facing layoffs because of arms contract cutbacks. This plant has had to cut its working force of several thousand men and women in half during the past three months.

First, general manager C. L. Jacob-

Ground Thread TAPS

These are Pratt & Whitney ground thread taps, each one a jewel of precision workmanship, metallurgy and heat treating. In 84 years we've made millions of taps. Mechanics in every civilized country in the world have used them — have come to know the long life and dependable performance which Pratt & Whitney ACCURACY assures. These taps are but one item in the complete line of quality small tools made by P&W.

We can deliver standard tools from stock, and give good service on special tools. Phone the P&W Branch Office nearest to you, for all that is top quality in small tools.

PRATT & WHITNEY

Division Niles-Bement-Pond Company

WEST HARTFORD • CONNECTICUT

son wrote each laid-off employee a personal letter, explaining that accumulation of ample stocks of ammunition by the Army necessitated the cutback in production schedules. Further, departmental supervisors called each of these workers into their offices and personally outlined in detail the factors involved.

Meanwhile, other industries in Evansville and its environs were advised of the layoffs and invited to come to the Evansville Ordnance Plant personnel office and set up interviewing and hiring facilities there. As employees turned in their badges they could immediately talk with representatives of other concerns looking for help.

A TOTAL of 5785 interviews were thus handled. No figures on actual hirings were available, but certainly a fair proportion must have resulted in new jobs, with that amount of interest evident.

The first annual report of the NWLB Tool and Die Commission of Region 11, at Detroit, declares that labor pirating in the district among tool and die workers is all but extinct, and that practically complete wage stabilization has been achieved.

Pay raises between February and November, 1943, were reported held to a 2.9 percentage increase, against a 19.7 percentage gain between January, 1941, and February, 1943, when the commission was set up.

As of the start of this year the commission had processed 1981 cases, including 987 applications for approval of voluntary wage adjustments affecting 45,909 workers. In addition, 326 cases covering 10,172 persons were processed jointly with the regional WLB. Indicative of the quieting down of the wage problem in Detroit tool and die shops was the fact that the backlog of cases at the start of this year totaled but 85, against a peak of around 200.

Most violations uncovered and handled by the commission have been in alley shops, the report indicated.

One paragraph in this report is of broader significance than the statistics of past activities. It reads: "When the war is over there may be far too many tool and die workers in proportion to the demand. Many upgraders who have never served an apprenticeship but who have been holding down jobs at high wages during the war will be competing for a limited number of available jobs after the war with skilled journeymen of many years' experience."

Steel Corp. Shipments Amount to 1,730,787 Net Tons

• • • **Shipments** of finished steel products by subsidiary companies of United States Steel Corp. for the month of January amounted to 1,730,787 net tons.

The January shipments compare with 1,719,624 net tons in the preceding month, an increase of 11,163 net tons and with 1,685,993 net tons in the corresponding month of 1943, an increase of 44,794 net tons.

Industry Advisory Committees

The War Production Board today announced the formation of the following Industry Advisory Committees:

Magnesium Sand Casting

WPB government presiding officer: George A. Bilque. Committee members are: Wiser Brown, American Magnesium Corp., Cleveland; B. A. Nagelvoort, Renown Stove Co., Owosso, Mich.; Fred A. Foxall, Bendix Aviation Corp., Teterboro, N. J.; Henry M. Reed, Jr., American Radiator & Standard Sanitary Corp., Louisville, Ky.; J. R. Could, Springfield Bronze & Aluminum Co., Springfield, Mass.; Samuel J. Walker, Michigan Light Alloys Corp., Chicago; Leo B. Grant, Dow Chemical Co., Midland, Mich.; J. A. Weinman, Los Angeles Magnesium Castings Co., Los Angeles; Lewis Moore, Jr., Marshall Stove Co., Lewisburg, Tenn.

Manganese Sulfate

WPB government presiding officer: Morris R. Stanley. Committee members are: C. A. Massuchelli, Carus Chemical Company, La Salle, Ill.; Fred B. Porter, Tennessee Corp., Atlanta, Ga.; J. F. Wischhusen, The Harshaw Chemical Co., Cleveland.

Test Instrument

WPB government presiding officer: E. R. Crane. Committee members are: A. H. Hotopp, Jr., Technical Device Corp., Bloomfield, N. J.; David Newman, Davan Co., Newark, N. J.; Paul Jackson, Jackson Electrical Instrument Corp., Dayton, Ohio; E. G. Perkins, Supreme Instrument Co., Greenwood, Miss.; V. E. Jenkins, Weston Electrical Instrument Corp., Newark, N. J.; Milton Reiner, Radio City Products Co., New York; J. J. McCarthy, Triumph Mfg. Co., Chicago; A. J. Lush, Rawson Electrical Instrument Co., Cambridge, Mass.

General Metal Office Furniture

WPB government presiding officer: George M. Chandlee. Committee members are: George H. Alter, Invincible Metal Furniture Co., Manitowoc, Wis.; C. L. Elofson, Art Metal Construction Co., Jamestown, N. Y.; E. A. Purnell, General Fireproofing Co., Youngstown, Ohio; William M. St. John, Yawman & Erbe Mfg. Co., Rochester, N. Y.; J. S. Sprott, Globe-Wernicke Co., Cincinnati, and H. S. Walcott, Domore Chair Co., Inc., Elkhart, Ind.

Precision Mechanical Spring

WPB government presiding officer: O. F. Fancey. Committee members are: Fuller F. Barnes, Wallace Barnes Co., Bristol, Conn.; Albert Bitzer, Jr., Illinois Coil Spring, Chicago; Edward Byrnes, Wickwire Spencer Co., New York; Henry Frontroth, Cleveland Wire Spring Co., Cleveland; Jack Culbertson, III, Duer Spring Co., McKees Rocks, Pa.; E. W. Feldt, Raymond Mfg. Co., Corry, Pa.; Lawrence Humason, Humason Mfg. Co., Forestville, Conn.; Lee Johanson, Lee Spring Co., Brooklyn, N. Y.; Warren A. Peterson, Wm. D. Gibson Co., Chicago, and C. M. Young, L. A. Young Spring Co., Detroit.

Shipments of Metal Cans in 11 Months

Monthly Shipments by Manufacturers of All-Metal Cans, by Product to be Packed January-November, 1943. Source: WPB Containers Division

The statistics in the table below are compiled from the reports (WPB-2707) of 76 manufacturers of all-metal cans and are for all known manufacturers. "Captive" plant manufacturers are included. The cans are manufactured from steel allotted under CMP Code 629 and Conservation Order M-81. Keys and handles for these cans are not included in the table. Wire used in the production of these items amounted to 704 tons for the 11-month period.

The shipment data on WPB-2707 reported in terms of the "number of base boxes of metal consumed in the manufacture of cans" have been converted into tonnage equivalents.

A metal can is defined by WPB as "an unused container which is made wholly from tinplate, terneplate, blackplate or wasteplate and is used for packing various types of products as shown in the table below. Fluid milk shipping cans are not included."

(Tons of Steel)

Months 1943	Fruits, Vegetables and Unspecified Food Products	Dairy Products	Meats	Fish	Military Rations	Non-Food	Monthly Total for All Products

How this DIAGRAM can help you . . .

Turn Idle Machine Time Into Extra Plant Output

If someone offered you a *tried and proved* method for selecting the right tool steel for each job—and told you how to simplify heat treatment and get better tools—you would probably hire him on the spot.

And that is just how the Carpenter Matched Set Method of selecting tool steel can be put to work in your plant.

In hundreds of plants, this tried and proved method is leading the way to tools that stay on their jobs longer, keeping machines operating more hours per month. It is reducing the number of times that tools must be reground, repaired and replaced. And simplified heat treating methods help you protect the hours that have gone into tool making.

To find out how you can put the Matched Set Method to work in your tool room, ask for your copy of the Carpenter Matched Tool Steel Manual shown here. It will point the way to better tools that can increase output from machines and presses. For your copy, drop us a line on your company letterhead.

The Carpenter Steel Company—121 W. Bern Street • Reading, Pa.

Here's your key to:

- **saving time and steel in the tool room**
- **getting better heat treating results**
- **increasing production per month per press**

In this 167-page *Matched Tool Steel Manual* you will find an alphabetical Tool Index and Steel Selector. At a glance, it quickly points the way to selecting the right tool steel for each job. Whether you need an oil-hardening, water-hardening or red-hard tool steel for the job, this Manual provides a definite system for arriving at the correct answer. And from there, it is a simple matter to follow the complete heat treating instructions.

The *Matched Tool Steel Manual* is offered free to tool steel users in the U. S. A., so for your copy write us a note on your company letterhead today.

Carpenter MATCHED TOOL STEELS

Washington . . .

L. W. MOFFETT

• Immediate creation of an Office of Demobilization under the supervision of a joint Congressional committee, with full power when peace comes, urged by the George (Senate) Committee.

WASHINGTON — The George (Senate) Postwar Committee's report on industrial demobilization is more than a well-thought out blueprint for dealing with tomorrow's economics. It is a summons to America to return to the precepts of Constitutional government. It is a document of historical significance.

Aware of the dangers inherent in the exercise of legislative authority by the President during the war and cognizant of the necessity of the delegation of practically unlimited powers, the George Committee has called for reinvestment in Congress of all authority loaned.

The report recommends the immediate creation of an Office of Demobilization under the supervision of a joint Congressional committee, to be supreme in the field of demobilization after hostilities and to bow only to the authority to the Office of War Mobilization so long as the war lasts. This would clearly short circuit the War and Navy Department policy of prohibiting not only peace production planning, but limited beginnings as well.

New legislation called for by the report would empower the Office of Demobilization to begin "NOW" to collect the most complete information with reference to factories that will be affected by war contract cancellation, their manpower requirements as war industries and as peace industries, their inventory and machinery needs in both categories. The report insists that the Office of Demobilization should make plans wherever possible to have the requisite peacetime machinery and inventories available to manufacturers at the earliest moment after peace comes; should have inventories of not only the goods that the government has on hand but those in the hands of the war production factories so that it can have formulated in advance the necessary plans for the disposal of those inventories and can determine the necessity of continuing or relaxing price controls, rationing, and allocation of materials to keep the economy on an even keel.

THE George Committee is so incensed by attempts by War Mobilizer Byrnes to prevent legislation being introduced on demobilization problems, that some consideration was given to recommending that the power to appoint the Director of the Office of Demobilization be refused the President. As it is, the Committee in placing the appointive authority with the President, reserved in the Senate the right of confirmation.

The following are the Committee's recommendations:

Termination—Contracts should be merged, wherever possible, and separate settlements made with suppliers as well as with prime contractors. The use of the over-all company claim probably would result in not more than 10 per cent of as many claims being filed as would be filed under the present method.

Legislation would be necessary to cut across the traditional concept of the expenditure of appropriations whereby the Army would have to be authorized to use its funds in the settlement of Navy contracts and vice versa.

It would be necessary to cut across legal concepts of privity of contract. Some contractors might object to separate settlement by the government of suppliers contracts. The way the government might work this out is to offer to buy supliers' claims.

Legislation should be passed specifically authorizing negotiated settlements, but these settlements should be based upon records sufficiently complete to be susceptible of post-audit for fraud as prescribed by the Office of Demobilization.

CONVENTIONAL preaudits of claims are utterly impractical and the Comptroller General should be relieved of any responsibility for preaudits.

The statute of limitations should be extended and provision made for the recovery of triple damage paid as a result of fraud.

The government should be required to pay interest on that portion of the claim which is not paid within 60 days. The interest rate should be 3 per cent.

The new agency should prescribe a uniform cancellation clause for each type of contract embodying the principles set out in the report with formulas applicable alike to both prime and subcontractors, whichever contractor should be given the option to adopt in lieu of any termination clause that may now be in contracts. The agency should adopt uniform rules for the filing of claims and the evidence and records necessary to support claims, and work out with the various operating agencies the speediest method of handling claims.

The training of contract termination personnel should be undertaken, and a regular reporting system designed.

Finance—The immediate payment of the contract price for all finished goods on hand and for 100 per cent of the direct cost of all inventories of raw materials and partly processed goods, and as large a percentage, up to 90 per cent of all other items in the claim as the contracting agency feels will afford the government reasonable protection.

Where the detailed audit of the direct cost of inventories is apt to cause delay, the procuring agency should be authorized to make advance payments and partial payments up to 90 per cent of the estimated total amounts due on terminated contracts and to base the estimates on contractors' certificates, or other evidence.

The procuring agencies should also be authorized to make direct termination loans, guarantee loans, similar to the present "V" loans. RFC and SWPC would also be permitted to get into the finance field, to keep plants in operation. Financial need or ability to repay will not necessarily govern financing, as the Office of Demobilization should be authorized to make the rules it wishes.

Plants—Government-owned property, machinery and equipment should be removed from the plants of manufacturers immediately. Inventories

may be moved within 30 days and stored. Plans should be made to convert government-owned plants into warehouses for storage of surplus property the very instant war work ceases and manufacturers should be informed which government plants will store the government property.

Other government-owned plants should be maintained as standbys, or sold at reasonable prices, but no plant disposal policy should be permitted to "exert a preponderant influence on the future course of that industry." (In such a category are steel mills, airplane factories, rubber, aluminum and magnesium plants, shipyards and pipelines). No government-owned plant should be sold in a manner to create or foster monopoly, but the fostering and encouragement of competitive enterprise should be a prime consideration.

The use or disposal of the foregoing "basic" industry plans may well have to be correlated with the Nation's foreign policy and Congress should legislate further in regard to them.

All plants suitable for the production of peacetime goods and not needed for national defense should be sold where this can be done without causing ruinous overproduction in any industry. An industry should not be severely damaged through overproduction merely for the purpose of selling a government-owned plant, but a plant should be held off the market only where its operation would result in the production of more goods than the market could absorb at reasonable competitive prices. The leasing of plants for a period sufficiently long to determine their operation on their economy should be authorized.

No government-owned plants should be scrapped and no surplus property destroyed except in circumstances where their continued existence would have such a profoundly harmful effect upon the national economy that their destruction appears imperatively necessary.

Civilian Output Stable!

• • • **For those who love to play with figures and statistics, Lawrence A. Appley, deputy chairman and executive director of the War Manpower Commission, this past week released some startling ones. Speaking before the American Management Association conference on industrial relations at Chicago, he stated that non-war production from 1939 through 1943 was down only 8 per cent and civilian production was maintained at "approximately the same level throughout the last four years." If such claims are accurate, many Americans are wondering where they can buy some of this civilian production. Summed up, Mr. Appley made the following claims:**

Pre-War Vs. War Production

	War Production, Dollars	Non-War Production, Dollars
1939 ...	1,400,000,000	87,200,000,000
1943 ...	67,000,000,000	79,900,000,000*

*Based on 1939 prices.

Center of Steel Output Moving Westward

Chicago

• • • **Upon completion** of the current steelmaking expansion program, the geographical center of American steel production will be one mile north and west of the town of Bucyrus, Ohio, indicating a westward movement of 31 miles since 1940, according to the American Iron and Steel Institute.

The new geographical center, about 80 miles from the Massillon-Canton steel district, actually is located in an abandoned red brick schoolhouse. Local soothsayers say that this is pure coincidence, and has no relation to the possible fate of much of the expansion program.

The new geographical center is farther westward than at any time in the industry's history, and its location resumes a trend broken in 1936, when the center moved eastward, and in 1940, when it hopped north and slightly east. Until 1933, the trend had been almost due west from the Atlantic Seaboard, where the industry was born. In 1874, when first compilations were made, the center was in Juniata County in Central Pennsylvania. Later the movement reflected the development of Pittsburgh as a great steel center, and eventually the construction of large plants in Chicago and other midwestern areas. In 1933 the epicenter was north and west of the town of Crestline, Crawford County, Ohio. By 1936, installation of new capacity to the eastward had drawn the center 13 miles east and one mile south of the 1933 point. At the end of 1940, growth in eastern Ohio districts pulled the center four miles farther eastward and six miles farther north.

With the new compilation the original trend is resumed.

No accurate data is available as to the center of steel consumption but large tonnage requirements for West Coast shipyards plus heavy ordnance activity in the Chicago district would place this point several hundred miles west of the production center, it is believed.

THE BULL OF THE WOODS — BY J. R. WILLIAMS

Gagemakers GUARD Against Costly Scrap

and FACILITATE ACCURATE WORKMANSHIP

Visual Gage and precision grinder in a modern gagemaking plant.

Beside each precision grinder in many gagemaking plants, a Sheffield Visual Gage guards against costly scrap loss and helps operators turn out highly accurate work. *The Visual is the most widely used instrument by which gages are checked.* Sheffield appreciates this trust and is vigilantly mindful of the obligation it involves.

Hundreds of production plants also use Visuals at their precision grinders to help reduce scrap and obtain a higher rate of accurate production. *The Visual is recognized throughout industry as the authority on PRECISION.*

DELIVERIES WITHIN TWO WEEKS can now be made on Sheffield Visual Gages of six different amplifications—500, 1000, 2000, 5000, 10,000, and 20,000 to one. WIRE OR WRITE.

WEST COAST . . . OSGOOD MURDOCK

• Carson City conference of committees on interstate cooperation bares some interesting angles in regard to western steel situation . . . Californians favor giving Geneva plant to westerners, and establishing new local basing point.

CARSON CITY, NEVADA—The conference of the committees on interstate cooperation, meeting here late last week, bared some interesting angles in regard to the western steel situation.

For instance, it appeared at the hearing which grew into a conference on interstate cooperation from California, Utah and Nevada, with a lone delegate from Oregon, that attorney general Robert W. Kenny of California and Chad C. Calhoun, vice-president of the Kaiser Co., Inc., favor passing the Geneva steel plant as quickly as possible into private, independent hands, owned and controlled by Westerners, putting the sale of its finished steel products, principally flat rolled, on a new local basing point.

Dr. J. H. Mahoney, director of the bureau of economics at the University of Utah, declared before the assembled official state representatives, principally from Utah and California, that pig iron will be made at Geneva cheaper than at Birmingham or Sparrows Point, and from $2 to $3 a ton cheaper than at Pittsburgh or Gary. Furthermore he declared for the first time publicly that a new area of coking coal has been proved in Utah, increasing by 300,000,000 tons the known reserves and available supply, so that Geneva need not be handicapped for coke or ore, which is now loaded on cars at the mine for less than $1.00 entire mining cost.

For this conference of the committees on interstate cooperation of Utah, California and Nevada a delegation of over 25 state senators, members of the assembly and department heads in the executive branch motored over the snow-deep Sierras from California. An equally large delegation was present from Utah, seriously concerned with disquieting rumors that have threatened the life and future of the Geneva plant. A lone Oregonian represented the Pacific Northwest, which region's pleas for industrial independence and freedom from the sundry yokes of California, Utah and the East may be expected next, as present war installations get producing and settle down for the long pull.

Two observers and listeners from the U. S. Steel Corp. management, one from Washington and one from Geneva, were present.

UTAH had held the floor for several hours. In the course of the presentation, particularly by H. W. Prickett, Salt Lake traffic counsel on freight rates, data and evidence had been introduced. Mr. Prickett forecasts a revised rail freight rate on structural shapes, plates and bars, from Fontana to Los Angeles, San Francisco, Portland or Seattle, of $5.31 per net ton, consistent with the present rate of $4.95 per gross ton on pig iron. If pig iron and finished steel can be made at Geneva below present eastern basing point costs, and with this freight rate less than half the old water rate inter-coastal, and less than a quarter the present all-rail rate from Chicago, then, indeed, the West Coast will be buying the cheapest steel it has ever been offered, at least officially and openly.

When Mr. Prickett finally introduced "Exhibit C," tabulating net final rate advantages per ton of Geneva over Fontana in marketing pig iron on the Pacific Coast of 52c., $3.11, $4.80 and $4.80 respectively at Los Angeles, San Francisco, Portland and Seattle, it evidently was just too much for Chad Calhoun of Kaiser Co. Asking the privilege of the floor he addressed himself something as follows:

"Our company entered the steel business on the West Coast for the double purpose of making plates for shipbuilding during the war, and postwar to produce and sell steel products in our geographical area at lower rates than the Pittsburgh-plus basis. We were in production 14 months after securing our authorization, whereas the Geneva plant is taking from 29 to 30 months. The war has made both these plants possible, so the West should cooperate in planning to build its industrial future around them both. One should complement the other."

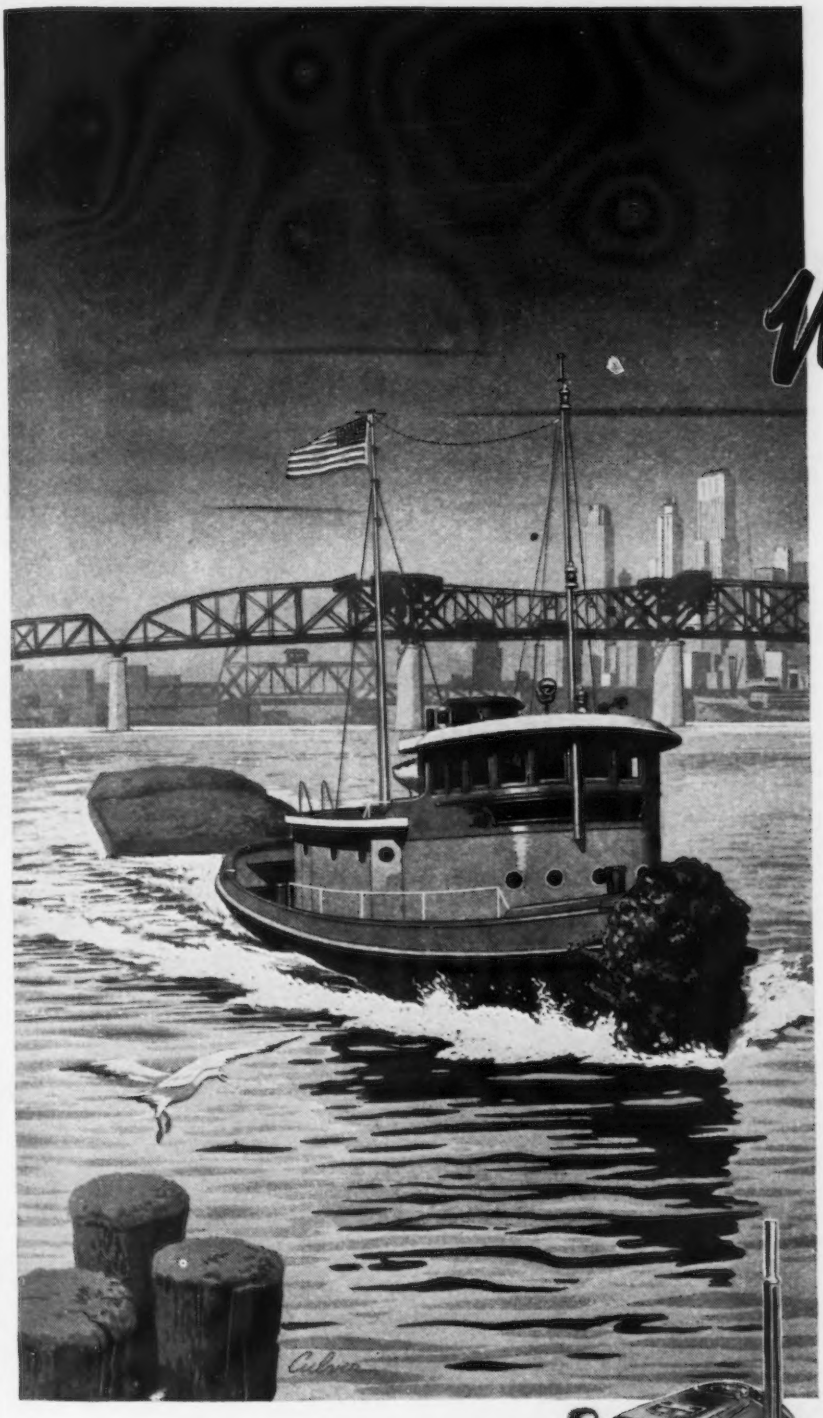
Mr. Calhoun asserted Geneva is the only steel expansion project under direct Government subsidy. He and his company are apprehensive about the future management and its policy, he indicated. "What kind of a deal will the Government make after the War?" he asked. "What will be the management? How much money is it going to cost to convert it to peacetime production?"

THESE are questions that others might pay $64 to have answered, but most steel men will question his implication that the "industrial maturity" (to use Dr. Mahoney's pat phrase) of the far West will be safer and more assured if Geneva is promptly turned over to some native independent westerners to own and manage, with no connections with the East, or with national operating steel corporate enterprise. It was by the Californians that the interest and management of the U. S. Steel Corp. and its subsidiaries in Geneva was suspect. The men from Utah seemed more apprehensive of strangulation by WPB or DPC or some Government decision.

In its resolutions the conference is asking for a representative from the far West on the steel industry advisory committee to WPB, for a new basing point at Geneva that will eliminate the "Pittsburgh-plus" formula for steel buyers on the West Coast, and for a statement from the Government agencies involved declaring their postwar intentions and assuring the far West that the Geneva plant will continue in operation, whether in public or private, Corporation or independent hands, so that other postwar planning involving jobs for increased population and utilization of wartime facilities and electric power may be primarily based on abundant, cheap, home-made steel.

On the second day of the conference, just before adjournment, Senator McCarran eloquently voiced suspicion of the WPB, as well as "monopoly, big business and eastern interests" in furthering the industrial development of the region west of the Rocky Mountains.

Senator McCarran asserted that



Work Horses OF THE WATERWAYS

Tow boats, ferries and barges may lack glamour, but the important jobs they do make the world's waterways much more useful than they would be otherwise. Our transportation system would be seriously disrupted if modern work-boat equipment were unable to absorb a great deal of punishment.

Among the power links developed by the Twin Disc Clutch Company in the past quarter-century is the Twin Disc Marine Gear. To work-boat operation, this Marine Gear brings the same high degree of stamina, reliability and efficiency characterizing Twin Disc's solution to so many other industrial power linkage problems. Enabling work-boats to do a better job, the skill and experience represented by this Twin Disc product thus takes all of us a step further along the road to better living.

Any user or builder of equipment involving driving and driven units can benefit from Twin Disc Clutch Company's specialized knowledge. You follow the example of many alert, successful manufacturers when you get the help of Twin Disc engineers on clutch problems. Their suggestions and advice cost you nothing. So write today for details showing what our products can do for you. TWIN DISC CLUTCH COMPANY, Racine, Wisconsin (Hydraulic Division, Rockford, Illinois).

Twin Disc Marine Reverse and Reduction Gears provide boat operators with the wider margin of safety which positive control and increased maneuverability assure. Their rugged construction, smooth operation and long wear life give unexcelled reliability.

only through pressure from the West and Congressional action could there be a "change in policy in the WPB."

He declared that Federal officials had tried to take over hundreds of thousands of square miles of the public domain of the West through "misuse" of the National Public Monuments Act. He intimated that Secretary of the Interior Ickes "wants to set aside the mining laws of the Western States."

Referring to the Fontana and Geneva plants, the Senator insisted that there was room for both plants. He said it was estimated that $20,000,000 in priority materials and machinery for the structural mill at Geneva were at the site but never had been unloaded.

Delegates to the conference were told that WPB has stopped work, at least temporarily, on the structural steel mill at the $180,000,000 government-owned Geneva works.

Attorney General Kenney of California asserted that 2,000,000 newcomers into industry in Western war plants "will be forced into a deflationary period by the older sections of the United States if the West is asked to fold up its industries and find some other way of supporting itself in the postwar period."

Also, just before adjournment, the following telegram from President B. F. Fairless of U. S. Steel Corp. was read and placed into the record:

"A representative of the Kaiser Steel interests is reported to have stated yesterday that the Geneva project was deliberately delayed by United States Steel. This is absolutely without foundation. Construction of this plant has been controlled from the start by priorities and scheduling of WPB and has been completed as expeditiously as government limitations would permit.

"I am forwarding copies of telegrams and correspondence of WPB and the Defense Plant Corporation urging higher priorities and elimination of delays due to giving other projects priority over Geneva. In addition we have had representatives in Washington and at plants of manufacturers holding orders for Geneva equipment, urging earlier deliveries.

"No such accusation has ever been made by WPB or DPC, the interested governmental agencies who at all times were fully advised of the construction progress of this plant."

Within a few minutes after this message had been read to the conference by the chairman, Calhoun issued the following statement over his signature:

"The Geneva plant was authorized in September, 1941. At all times it has had a higher priority than Fontana. In June, 1943, WPB reviewed all emergency steel projects and established urgency ratings for the seven most important and placed Geneva ahead of Fontana. The Fontana plant has been producing steel plate since August, 1943, even though handicapped by the priority preference accorded U. S. Steel on Geneva. Geneva, with its higher priority, has not produced any steel plate yet."

Informal and unofficial spokesmen from Utah who should be in a position to know, stated that there have been times when Fontana had AA1 rating and Geneva A3, and that on the preference list of emergency steel projects Fontana stood third and Geneva twenty-third.

In the opinion of some persons attending the conference, "it is possible that neither all facts nor all fists have yet been banged on the table."

The first open hearth at the Geneva plant started operations early this month, to be followed by additional units quickly. This plant is operated for the United States Government by Geneva Steel Co., U. S. Steel Corp. subsidiary. In addition to the open hearths which will be started, it is expected that another battery of 63 by-products coke ovens will be started during this month. Some of the rolling mill facilities, designed to supply ship plates for West Coast shipbuilders, are scheduled to be ready for operation late in March.

Columbia Steel Co., West Coast subsidiary of U. S. Steel, began construction of the fully integrated Geneva works in April, 1942, for the Defense Plant Corp.

The Kaiser plant was started in early 1942 and blew in its first blast furnace in December, 1942. First steel was made in May, 1943. Plate production began in August, 1943. Kaiser financed the plant by borrowing from the Reconstruction Finance Corp. against the earnings of his shipyards. As indicated in last week's West Coast column, page 88, Kaiser is attempting to reduce his costs in the expectation that keen competition will be experienced on the Pacific Coast. Also in last week's issue, pages 100 and 101, appeared statistics on western steel capacities and a discussion of postwar trends.

Kaiser Purchases Fee Title for Mine

San Francisco

• • • Kaiser has purchased from the Southern Pacific Land Co. fee title to the Eagle Mountain Iron Chief ore deposit in Riverside County for the reported sum of approximately one million dollars. Harlan H. Bradt has purchased contract for ore on installment basis for a number of years. Thus, Kaiser it appears is not free to mine or use the ore except by purchase from Bradt.

Flat Rolled Steel Makers Form New Trade Association

Pittsburgh

• • • **Flat rolled steel** makers recently formed an association here to be known as the Steel Manufacturers Association. The forerunner of this group which was dissolved last year and was known as the National Association of Flat Rolled Steel Manufacturers.

The new association which has offices at 1711 Oliver Bldg., Pittsburgh, will carry on activities similar to those endeavors of the one which was discontinued. Harry H. Burris, who was associated with the old outfit, has been made secretary-treasurer of the newly formed association.

Purposes of the organization include: Preservation of quality standards, cooperation with the Department of Commerce in establishing simplification of standards, collection and dissemination of information concerning flat rolled steel products and new uses for steel items.

Helping to "BRING 'EM BACK ALIVE"

Nothing in this war is more heartening than the large number of pilots and plane crews who come back alive from missions of extreme hazard.

Case after case has occurred where planes suffered terrific punishment, yet the pilots managed to bring them home. It is a tribute to the splendid skill of our pilots and the remarkable quality of our planes.

Vickers Hydromotive Controls are an important factor in the exceptional quality of many American combat planes. These high pressure oil hydraulic controls are dependable, accurate, easy to operate, easily adjusted, insensitive to shock and vibration . . . reliable no matter how tough the going.

Vickers Hydraulic Equipment is also used to advantage for the control of many types of production machines . . . machines that are helping win the war . . . machines that will help win the peace.

PERSONALS

• **Bennett S. Chapple, Jr.**, formerly assistant manager of sales for Carnegie-Illinois Steel Corp. in the New York district, has been appointed assistant to president L. Gerald Firth of Firth-Sterling Steel Co., McKeesport, Pa. Mr. Chapple's previous associations were with the Insulated Steel Construction Co., Middletown, O., and American Rolling Mill Co.

• **Alex Krueger** has been appointed manager of the Corpus Christi operations of San Antonio Machine & Supply Co., San Antonio, Tex. He has been associated with the company for 25 years, having been in charge of all engineering sales until his recent appointment.

• **Donald A. Sutherland** has been appointed field engineer in charge of sales and sales promotion activities for McCulloch Engineering Corp., Milwaukee. Before coming to McCulloch, Mr. Sutherland spent ten years with Fairbanks-Morse in St. Paul.

• **H. H. Barnes** has been made director of the proving ground section of General Motors at Milford, Mich. Mr. Barnes succeeds **Ernest E. Wilson** who died recently.

• **Herschel J. Wood** has been appointed southwestern representative of the Lebanon Steel Foundry, Lebanon, Pa. He will be in charge of this company's new office at Houston, Texas. Mr. Wood was formerly associated with the Elastic Stop Nut Corp. of America.

• **Raymond C. Franklin** has joined the sales force of the Continental Screw Co., New Bedford, Mass.

• **J. S. F. Carter** has been appointed engineer in charge of design and engineering service for the process division of S. D. Hicks & Son Co., Inc., Boston. Mr. Carter had been chief design engineer of the Cherokee Ordnance Works and was previously associated with the Lummus Co. & DuPont.

• **Lee W. Ralston** has been named supervisor of industrial relations for the manufacturing and repair department, Westinghouse Electric and Mfg. Co., Pacific Coast District, with headquarters at Emeryville, Cal.

• **C. B. Langstroth** is resigning from his position as welding consultant after 12 years with American Locomotive Co., New York. Previously he was vice-president of the Detachable Bit Co. of America and also with A. O. Smith Corp., Milwaukee.

• **Gordon F. Ives** has been appointed advertising manager of Walter Kidde & Company, Inc., Bloomfield, N. J., replacing **C. E. Gischel** who has been appointed director of product development, in charge of postwar planning.

• **Francis S. Norton** has been made general traffic director for the Fisher Body Division, Detroit, succeeding **C. A. Sullivan**, retired.

• **George H. Meilinger**, former Westinghouse refrigeration sales development manager, has been appointed manager of the company's household refrigeration department to direct postwar plans for the refrigerator production program of the Westinghouse Electric Appliance Division.

• **Albert J. Berdis** has been appointed assistant to general superintendent of Carnegie-Illinois Corp.'s Irwin Works. He was formerly chief engineer at Irvin Works. Succeeding him as chief engineer at Irvin is **Klauss Egge**, who had been tin mill engineer in the company's general office.

• **DeWitt McKinley** has taken over the management of the McKinley Iron Works, Fort Worth, Texas, upon the retirement of his father, **E. H. McKinley**.

• **R. N. Shields**, formerly general supervisor of the eastern district, U. S. Steel Corp. subsidiaries, has been appointed assistant traffic manager eastern district. **R. F. Holtz** has been made assistant to traffic manager, eastern district and **R. J. Dods**, general supervisor, traffic department.

• **G. H. Tobelman** has joined the Wolverine Tube division of Calumet & Hecla Consolidated Copper Co., Detroit, as manager of the eastern territory with offices in New York City. For the past 11 years he has been connected with the Bridgeport Brass Co.

• **William A. Patterson**, president of United Air Lines, Inc., has been elected a member of the board of directors of Stewart-Warner Corp., filling the place left vacant on the directorate by the death of **Frank A. Ross**, senior vice-president.

• **Kreston T. Sorensen**, has joined the staff of William Sellers & Co., Inc., as assistant to the president.

• **Harry A. Spieth** is new general superintendent of the Oregon Steel Foundry Co. at Portland. For 19 years he has been manager of the Western Steel Casting Co.

• **Harold Metzendorf** has been appointed advertising manager of Southern States Iron Roofing Co., Savannah, Ga. Mr. Metzendorf has had more than 17 years of advertising, sales promotion and market research experience.

• **Roland Sheriff**, works manager and **G. Briggs Weaver**, chief design engineer, have been made directors of the Indian Motorcycle Co., Springfield, Mass.

ADAM J. HAZLETT and WILLIAM J. CREIGHTON, left to right, have been elected general manager of sales and executive vice-president respectively of Jones & Laughlin Steel Corp., Pittsburgh, as announced in the Feb. 10 issue, page 84.

• **A. J. Tigges** has been appointed manager of consulting engineering for all divisions and subsidiaries of the Baldwin Locomotive Works, Philadelphia, including locomotive and ordnance. In addition, Mr. Tigges will have charge of engineering of new products and new applications relating to postwar plans.

• **John W. Humphrey**, formerly superintendent of Carnegie-Illinois Steel Corp.'s Vandergrift, Pa., plant, has been appointed assistant to general superintendent of the company's Youngstown district. **Arno L. Billeter**, previously assistant to general superintendent of the Irvin Works, is successor to Mr. Humphrey's former position.

• **William O. Wilson** of Evanston, Ill., has been appointed a commercial vice-president of Worthington Pump & Machinery Corp. In his new capacity, Mr. Wilson will be responsible for general supervision and direction of all of Worthington's commercial activities in the Chicago, St. Louis, Kansas City, and St. Paul district office territories, with his headquarters at the Chicago district office.

• **Harry K. Werst** has been made vice-president in charge of manufacturing for Elastic Stop Nut Corp. of America, with plants in Union, N. J., and Lincoln, Nebr. Mr. Werst, a partner in Booz, Allen & Hamilton, has had extensive experience in manufacturing operations, and will be in complete charge of manufacturing processes in all of ESNA's operations.

• **D. M. Morewood** has been appointed assistant to E. G. Plowman, vice-president in charge of traffic, U. S. Steel Corp. of Delaware, Pittsburgh. Mr. Morewood was formerly assistant traffic manager for the eastern district of U. S. Steel Corp. subsidiaries. He was first employed by Carnegie Steel Co. in 1914, and transferred to U. S. Steel subsidiaries at the time of the consolidation of traffic departments.

• **Karl L. Konnerth**, formerly chief engineer of H. C. Frick Coke Co., has been appointed assistant to the president in charge of engineering of this and associated U. S. Steel subsidiary companies. He has been with the company since 1926. **George M. Thursby**, now assistant secretary of the company was also appointed director of industrial relations for the U. S. Steel subsidiary companies. He has been assistant secretary of the Frick company since 1939. **August J. Breitenstein**, formerly assistant chief engineer, has been named chief engineer, to succeed Mr. Konnerth. He has been with the Frick Co. since 1941.

• **William E. Harrison** has been appointed assistant fuel engineer for Lukens Steel Co., Coatesville, Pa., and its subsidiaries, By-Products Steel Corp. A graduate of the University of Pennsylvania, Mr. Harrison joined Lukens in 1934.

• **Robert H. Clymer** has been elected vice-president of Luria Brothers & Co., Inc., Philadelphia, in charge of yard and plant operations. Mr. Clymer started with Luria Brothers in 1905 and has since occupied various executive positions with the firm.

HARRY K. WERST, vice-president in charge of manufacturing, Elastic Stop Nut Corp. of America.

ROBERT H. CLYMER, vice-president, Luria Brothers & Co.

OBITUARY...

• **William B. Mayo**, formerly chief engineer of Ford Motor Co., died recently in Detroit. Mr. Mayo was in charge of the building of the River Rouge works.

• **Alfred G. Suelflow**, president of the Felins Tying Machine Co., died Jan. 29 in a Milwaukee hospital at the age of 63 after a short illness.

• **Herman C. Haehle**, former plant manager for the Harnischfeger Corp., Milwaukee, and a director of Ampco Metals, Inc., died at his home in Milwaukee after a short illness. He was 78 years of age.

• **William O. Vilter**, president of the Vilter Mfg. Co., Milwaukee, died Jan. 31 in a Milwaukee hospital after a short illness. He had been active in the business for 62 years until last November.

• **Alva L. Grinnell**, senior employee of the sales department of the Rustless Iron & Steel Corp., died on Feb. 3. He had been ill for several years.

• **Robert W. Thomas**, director and treasurer of Thomas Machine Mfg. Co., Pittsburgh, died Feb. 6, at his home in Glenshaw, Pa., after an illness of several months.

• **Andreas Hartel, Jr.**, senior member of the firm of Hartel Brothers & Co., South Boston, steel merchants, died Feb. 4. He was 75 years old.

• **Louis Caputo**, Builders' Iron Works, East Boston, died recently. He was connected with the iron industry the past half century.

• **George A. Burman**, 76, vice-president of Wolverine Foundry Supply Co., Detroit, died recently.

• **Harry N. Omer**, 83, assistant sales manager of Great Lakes Steel Corp., Detroit, died recently. Mr. Omer had been with the company for nearly 20 years.

• **William J. Filbert**, 78, a director of U. S. Steel Corp. and a member of its finance committee and formerly chairman of the finance committee, died Feb. 4 at his home in New York, after a brief illness as announced in the Feb. 10 issue, page 84.

• **Andrew J. Dietrich**, president of Dietrich Brothers, Inc., Baltimore, died recently.

Fatigue Cracks . . .

BY A. H. DIX

Williams, 1; Oliver, 0

• • • Ole K. Olsen started it by asking, "Why the left-hand twist drill in the Dec. 9 'Bull of the Woods' cartoon?" H. L. Blood replied, "It is no L.H. twist drill; it's a spiral type reamer."

Our technical editor, Frank Oliver, said the helix angle is too acute for a reamer. But a reamer it is. Hark to the voice of authority:

> May I administer a gentle rebuke to your Technical Editor, Frank Joseph Oliver, in his implied criticism of my good friend J. R. Williams. In substantiation of the technical point involved in his criticism of the reamer's helix angle, I give you below the actual picture of a helical taper pin reamer which will prove Mr. Williams' picturization correct.

> We can identify this as a Pratt & Whitney Helical Taper Pin Reamer, List No. 458 No. 9.
>
> —*E. C. Shultz, Advertising Manager, Pratt & Whitney, Division Niles-Bement-Pond Co., West Hartford, Conn.*

The "Bull of the Woods" creator has never been known to blow a technical blue note, and we will never swerve again from the straight Williams party line. If he draws a curved drill for boring curved holes it will be gospel to us.

Mop Up

> I seize this fleeting moment to smite the neck so naively protruded. There is a quick spiral taper pin reamer . . .
>
> —*Deac*

Now, he tells us.

Weathers Note

• • • Deac, who gripes about the trend toward sticking esses on words that used to be singular (freedoms, skills, equipments, etc.), will pay no visits to New England until he can paste his A book in his scrapbook, for the New Haven Railroad has pluralized the weather. Slogan: "Dependable in all weathers."

First Prize to Jeremiah

• • • If our "whodunit first" file had been up to date we could have saved ourselves a lot of trouble in answering the question about the father of the machine cut nail. For the entire history is in the November, 1943, issue of the American Iron & Steel Institute's "Steel Facts."

Jeremiah Wilkinson, of Cumberland, R. I., was the first of several Yankees to toll the bell for an ancient handcraft. He invented his machine in 1777. The record is conspicuously silent as to outlanders' contributions. To satisfy our curiosity, will the English member of this page's loyal army of eighteen readers please knock off all other work for a week and mosey around the Kensington Museum in an attempt to account for his forebears' failure to help push the ball along? Were the hand nailmakers' unions or manufacturers' associations that strong?

> *Wire nails came much later. In* 1851 *John Hassall, of Brooklyn, N. Y., invented the first machine in this country. He founded John Hassall, Inc., whose advertisements you see in your favorite family journal.*

Before we bid farewell to nails, just one more fact—the average American dwelling contains about $14 worth. The hand wrought kind cost so much that when American settlers moved from one place to another they would burn down their cabins to salvage the nails.

Help Wanted Ad, War Style

• • • Chet Ober, one of your favorite family journal's advertising ambassadors, clipped from the Stamford, Conn. "Advocate" the most compelling help wanted ad we have seen in a long time.

It consists mainly of a large photograph showing a completely equipped workroom, bare of people. The caption begins:

> These empty benches and chairs at The Yale & Towne Mfg. Co. must be filled . . . We need women war workers . . . to produce a vital new electrical device for the American Air Forces . . .

No Moses to Lead Us

• • • What we miss these days is a business prophet with the impressive, ex cathedra manner of say a late '20s Babson. In those days the future was always an open book. It was all scientifically worked out. By adding carloadings, brokers' loans, kilowatt output, and furnaces in blast, with just a dash of lumber output in board feet, the seers knew exactly what stage of the business cycle we were in.

Armed with only a composite index figure you could steer your ship through any sea. It was all very exact and highly comforting. But the sun that set on business prognosticating late in October 1929 never rose again.

The absence of an authentic Moses has created a bull market in the home-made economic conviction business. Convictions, the sound kind anyway, are based on information, and inasmuch as your favorite family journal's sole reason for existence is the gathering and dissemination of information, we are much interested in current fashions in conviction-forming.

We observe that the passion formerly lavished on index figures has given way to a yearning for advance or early advice on changes in trade trends. This is our meat. We have no prognosticators on the payroll, but we do have a sharp-eared listener at every strategic point throughout the country. What these human seismographs pick up is teletyped to the brain center at the other end of the aisle. Every Tuesday afternoon Don James, our news chief, sits himself down at his Remington and writes a distillation of what the seismographs detect.

This distillation meets your eye each week under the title "This Industrial Week" (see page 100). It is expertly done, as proved by the fact that whenever we put our reader interest pyrometer on it the needle does a Gundar Hagg to the right.

Stoppers

When "Camouflage wool" comes back to the kitchen —*American Steel & Wire Co.*

So the U.S.S.R. came to Lewis—*Lewis Foundry & Machine, Division of Blaw-Knox Co.*

Puzzles

The hands on last week's chronometer will be in exact coincidence at no time other than at 12:00:00 o'clock. They will be closest to coincidence at 8:43:43.64394 and 3:16:16-.35606. At these instants the second hand will be in coincidence with the hour hand, and the minute hand will be zero degrees, 30 min., 02.736 sec. (of arc) away. So they miss coinciding by 1/12th of a dial-division at the points of closest-to-coincidence.

"If," says H. L. Blood, "you get an answer to this within 15 seconds it's wrong."

A metallurgist has a number of cube-shaped specimens. He wishes to identify them and hits upon the idea of grinding some sides and leaving others unground. How many cubes can be distinguished by this method?

"FAIRBANKS-MORSE SCALES—ARBITERS OF BUSINESS"

The Decision Is Final!

Since 1830—Fairbanks-Morse Scales have been rendering split-second decisions recognized as *fair* and *absolute* by buyers and sellers alike.

They are accurate, reliable, honest weighing decisions that have exerted a profound influence on the progress of industries and the welfare of nations.

The accuracy and long life built into Fairbanks-Morse Scales can give you added protection—distinct *plus values* wherever fast—accurate—efficient weighing is essential.

They are tangible *values* developed and pioneered by a company that places no ceiling on whatever it takes to make the finest scales possible to produce.

Dear Editor:

DOG EAT DOG

Sir:

I am one of the multitude of foremen caught on the fence between management and labor as represented by unions, highly respected by both for our technical knowledge and ability and utterly disregarded by both as a group of individuals with equal rights and desires. Of late, there is a nation-wide movement of foremen to organize, too, for self-protection. The large unions, this time a step ahead of business, are greeting this dissatisfied group with open arms. All groups, though, are forgetting the investors. Government is conscious of them only as a tax income group because they have not organized into a joint pressure group. All groups have their respective places in the sun and, in our democratic way of life, with a dog eat dog attitude, inherent in all of us, government is the proper arbiter of all inter-group differences in either wartime or peace.

Therefore, I say that in its editorial policy THE IRON AGE should strive always for greater cooperation between all these groups for the good of themselves and their country.

F.R.A.
Haddon Heights, N. J.

PLASTIC SEAL

Sir:

Will you please send us a clipping of the article, "Sealing Tube Ends With Plastic," in your Nov. 4 issue.

R. H. STEINBRINK,
Chief Inspector
Cooper-Bessemer Corp.,
Mt. Vernon, Ohio

WAGE INCENTIVES

Sir:

This office is faced with a problem of assembling data on wage incentives. Will you please send clippings of these articles: "Practical Wage Incentive Plan," Sullivan Machinery Co., THE IRON AGE issue of Dec. 4, 1941; "Lincoln Electric Co. Wage Incentive Plan," issue of June 25, 1942, and "Workers Trade Ideas for Money," issue of Oct. 22, 1942.

STANLEY W. A. INGRAM,
Consultant, Technical Advisory Service
Smaller War Plants Corp.,
1031 South Broadway,
Los Angeles 15

HYDRAULIC SYSTEMS

Sir:

Will you please advise me of any text book or similar printed material covering the operation, maintenance and repair of hydraulic systems on machine tools that could be used for the instruction of machine repairmen.

KNOX A. POWELL,
Research Engineer
Minneapolis-Moline Power Implement Co.,
Minneapolis

● Articles on machine applications of hydraulic systems have appeared in the technical press from time to time, but the only book we know of on the subject is, "High Pressure Oil Hydraulics," published by the North American Press, Milwaukee. This small book (160 pages), deals particularly with pumps and ram equipment, but some of the fundamental principles would apply as well to machine tools.—Ed.

MACHINE DEBURRING

Sir:

In a recent "News Front" there appeared a few lines stating that machine deburring is rapidly replacing hand deburring. Can you supply us with the name and address of a concern that can give me further information?

JAMES N. McLAUGHLIN,
Production Supt.
Robert Mitchell Co., Ltd.,
750 Belair Ave.,
Montreal

● Write to G. O. Rowland, Osborn Mfg. Co., Cleveland, Ohio.—Ed.

HYDROGEN PRESSURE

Sir:

In one of your 1943 issues you stated:

> "An experiment is recorded in which a steel bar was bored to provide a hollow cylinder that could be fitted with a pressure gage. Hydrogen was evolved from the other surface of the tube by electrolysis and after a short time the pressure rose on the inside to 4300 lb. per sq. in., the limit of the gage."

Kindly let me know where the above experiment is to be found.

RALPH TARSHIS
2215 Mermaid Ave.,
Brooklyn

● In the 2-part article, "Effect of Moisture in Blast Air," by R. J. Cowan, in The Iron Age issues of Nov. 12 and 19, 1942.—Ed.

NE STEEL CHART

Sir:

We have found your NE Steel-Standard Steel Chart very useful in the substitution of critical alloys. Will you kindly send us three more copies?

FRED J. McFARLAND,
Raw Material Supervisor
Boeing Aircraft of Canada, Ltd.,
Vancouver, B. C.

UNION DEMANDS

Sir:

Will you please send us clippings of these articles in your Dec. 9 issue, "Unions Expected to Demand 40-Hour Week (page 102) and "Steel Union's Demands Include Post-War Provisions" (page 101).

H. BRUDNEY,
Director, Industrial Relations
Conmar Products Corp.,
140 Thomas St.,
Newark, N. J.

ENEMY PATENTS

Sir:

Will you please advise how we may secure foreign patent descriptions as mentioned on page 118 of the Jan. 27 issue. You state this information is in the Nov. 4 issue on page 95 but we are unable to locate this copy.

J. W. BOWMAN,
Director of Purchases
Northwestern Steel & Wire Co.,
Sterling, Ill.

● Copies may be obtained for 10c each from the Commissioner of Patents, Washington 25, D. C. Don't send stamps. Thumbnail descriptions of the patents themselves are being published serially in The Iron Age. A 26-page booklet, reprinting all the lists published in The Iron Age up to and including the issue of Jan. 20, may be obtained by sending 24c (stamps accepted) to The Iron Age, 100 E. 42nd St., New York 17.—Ed.

POSTWAR KITCHEN

Sir:

I am astonished by Mr. Segeler's revelation, that an inquiry from England for data on modern kitchens was turned over to the Modern Kitchen Bureau of the Edison Electric Institute.

Certainly you know that gas is the accepted fuel in this country as well as in England, and I am curious to know what prompted you to turn the question over to the Electric Institute.

VICTOR STARZENSKI,
Vice President
Hudson Valley Fuel Corp.,
Troy, N. Y.

● Slighting gas, the pre-eminent kitchen fuel both here and in England, was furthest from our minds. We were thinking of electric fruit squeezers, mixers, toasters, etc.—Ed.

FLAME HARDENING

Sir:

I understand you have reprinted a 5-part series of articles on "Flame Hardening." If this is available I would greatly appreciate a copy.

J. J. LAUDIG,
Research Engineer
Delaware, Lackawanna & Western
Railroad Co.,
Scranton, Pa.

● We have no copies left. You might be able to get one from the author, A. L. Hartley, R. K. LeBlond Machine Tool Co., Cincinnati.—Ed.

ISOTHERMAL QUENCH BATHS

Do you have reprints of Harold J. Babcock's two-part article, "Isothermal Quench Baths Applied to Commercial Practice," in your Feb. 3 and 10 issues?

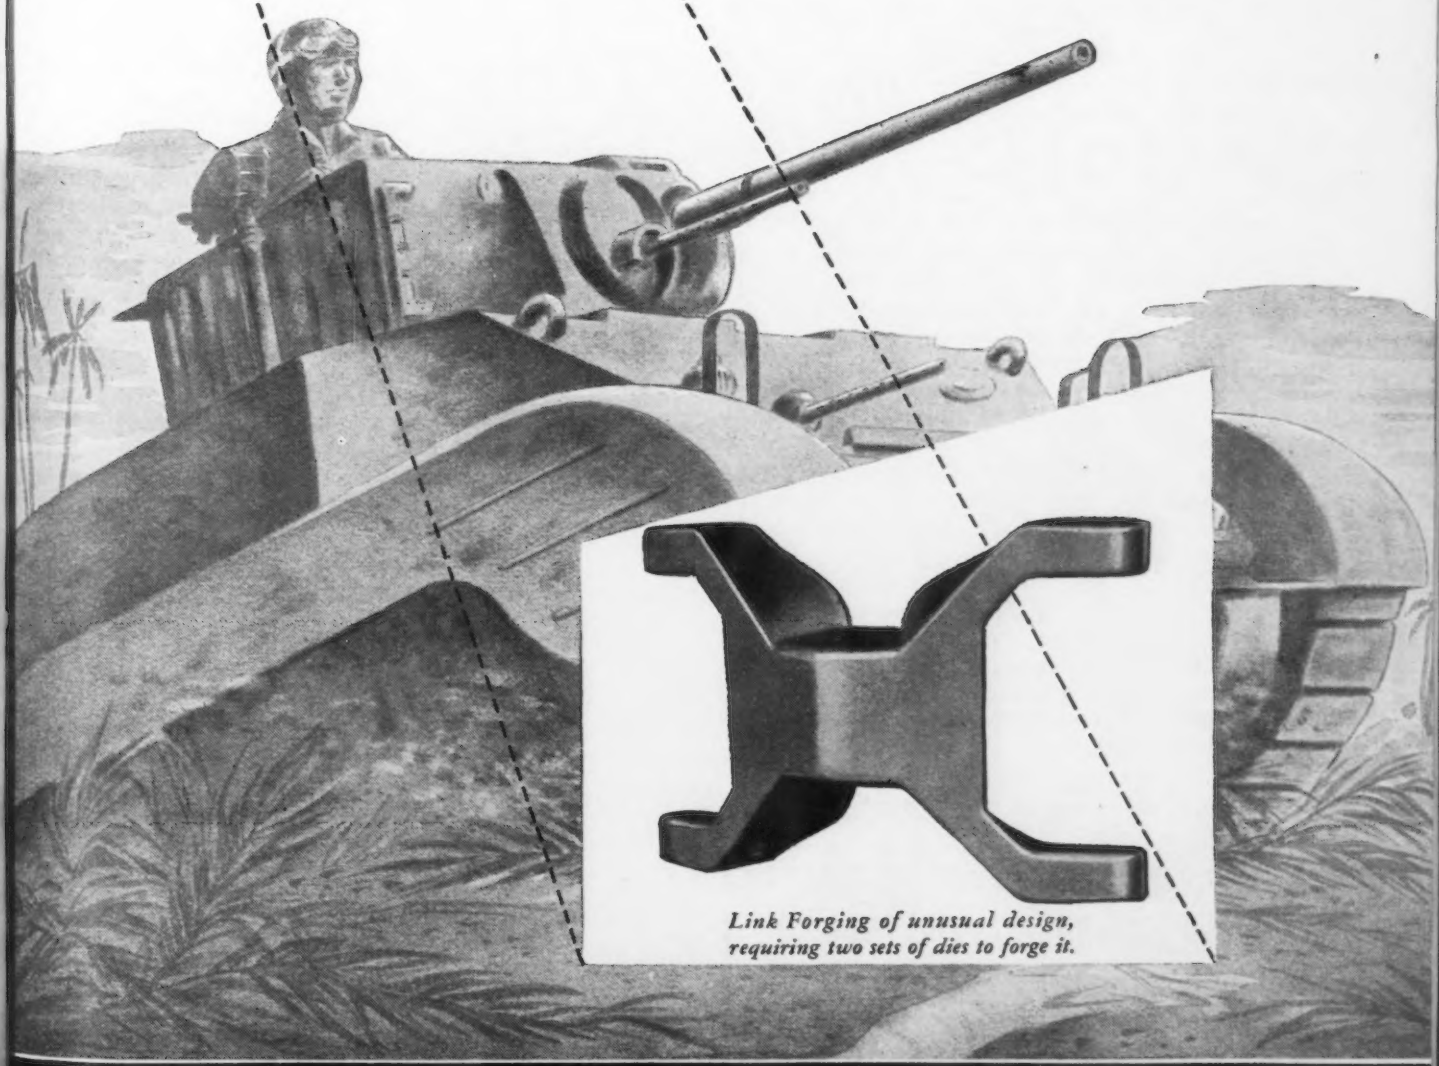
W. H. McCORMICK,
Metallurgist
Crucible Steel Co., of America,
Park Works, Pittsburgh

● Reprints have not been made, but clippings are being sent you.—Ed.

T&W FORGINGS

usually cost less at the point of assembly

Plus or minus a few minutes of time may be as vital a factor in meeting post-war competitive conditions as it is today a vital factor in the production of war equipment. Plus or minus a few minutes of time at each stage of operation in producing and finishing a forging can make an important difference in the time it takes to get the forging to the assembly line, and an even more serious difference in the cost of the forging at the point of assembly. T & W Forgings formed to close tolerances, usually require less machining and finishing—*a fact which makes them cost less at the point of assembly.* Ask a T & W forging engineer for suggestions which may help you meet post-war conditions.



Link Forging of unusual design, requiring two sets of dies to forge it.

This Industrial Week . . .

- ***Small Business Gets Big Doses of Sympathy from Officials***
- ***Steel Industry Experiencing Another Period of Heavy Ordering***
- ***DPC's Search for a Yardstick Proves Irksome to Industrialists***

ONE of the noteworthy changeovers of the war has been the apparent switch in thinking at Washington on the subject of small business. The trend toward all-out assistance began assuming significance in Congress several months ago and was emphasized during the past week by separate statements of several officials.

According to Donald M. Nelson, the first opportunity to reconvert must be accorded the nation's small enterprises. This was followed by the declaration of Jesse Jones that small businesses and returning veterans should be given precedence in the purchase of surplus materials, perhaps aided by Reconstruction Finance Corp. which within the past week also revealed that it is prepared to loan manufacturers money to cover reconversion costs.

Will all this talk about small business amount to anything? Observers at Washington feel that some good will be accomplished. On the sidelines, small businessmen were not cheering too loudly at this early stage, perhaps because several exhibitions of resolution over recent years at Washington proved to be of little worth.

The steel industry itself was interested in the small business topic this week because of WPB's removal of production directives of the very smallest non-integrated steel producers. While freeing the smaller firms of the necessity for producing specified products under strict controls, the move heightens the problems of non-integrated mills in regard to their raw material.

MEANWHILE, the steel industry is experiencing heavy buying reminiscent of former peak periods during this war. Backlogs at most companies definitely are higher than they were a month ago, led by flat rolled orders, structural steel awards, and pipe bookings. Added demand for alloy bars also appears likely to materialize soon as a result of a new ammunition project.

The placing of large tonnages by farm equipment makers is a feature of the current steel markets, while Maritime and Navy orders remain brisk and include sizable requirements for Navy pontoons for 1945.

A little relief in the hectic flat rolled steel picture is afforded by the start of operations at the new Granite City sheet mill, which increases capacity by about 25,000 tons per month. The new plate mill in Texas also is believed ready to start operations.

In Nevada last week an interesting conference on the western steel situation was held by commissions on cooperation between the western states. Differences of opinion between U. S. Steel Corp. and the Kaiser Co. came to light and Senator McCarran attacked the WPB. The decentralization argument also involved Jesse Jones at Washington when he was asked for his views on steel mills and closed aluminum plants.

JONES' testimony reflected indecision on most counts. This has been a subject of comment in industry. For instance, detecting reluctance by the Defense Plant Corp. to make prompt decisions regarding the sale of some of its properties, a number of industrialists are beginning to look askance at the agency's apparent search for a yardstick which it seems to want to apply universally. It is pointed out that a common denominator governing sales will be impossible to attain since the projects were built under different conditions, in different areas and for varying purposes. The viewpoint of the industrialists is that the agency might better establish precedents and keep its plants in useful production in this nation than to wait in vain for a policy to be laid down. Like a pilot with a load of live bombs, the DPC, about which little is known by the public, may have to make quick decisions.

In the machine tool industry, where there has been much heavy thinking since orders began to drop months ago, a ray of hope is now discerned by some executives in the modernization needs of American industry. It is pointed out that in 1939 the nation's factories owned a huge total of machines 10 years or older and that since that time many of these machines along with some of the newer ones have been rendered unfit through high speed war production. Many of the 800,000 machine tools made during the war for use in this country can be utilized under properly planned modernization programs.

Other highlights of the week include clarification by Carmen Blough of WPB's role in tax amortization, introduction of the Murray-George "Omnibus Termination Bill" in Congress, and an indication that Donald M. Nelson has decided to oppose cartels.

BEARING out previous forecasts that war contract cutbacks would be heavy this quarter, individual announcements during the past week in-

dicated plans for the closing in whole or part of numerous plants making munitions and other items. In some cases, retooling was inaugurated and in others sales of plants were under consideration. Apparently no work so far has been on the releasing of material for civilian production for the widely-heralded experiment to aid small plants in three cities.

Contract cutbacks and terminations now amount to approximately $14,000,000,000 by the War Department alone and another $2,000,000,000 has been canceled to date by the Navy.

Civilian allotments for carbon steel for second quarter have been cut 7 per cent below requests, but represent a modest gain of 55,000 tons over the first quarter.

The past week brought several important changes in government controls covering the distribution and use of metals. An amendment to CMP regulations permits a firm to use surplus materials to fill another authorized production schedule if he changes the original allotment account. Modifications were announced in the scheduling order, M-293. A new form WPB 1319 was announced to save much paper work and there were other changes aimed at simplified procedures. It was learned that automatic extension of controlled materials allotments may be enlarged to include large consumers as well as small producers.

In spite of recent claims of surplus aluminum, Philip D. Wilson, director of the WPB Aluminum and Magnesium Division, last week warned that aluminum sheet production must be stepped up if 1944 aircraft requirements are to be met.

This week's national steel ingot rate is off one point to 96.5 per cent of revised capacity from 97.5 per cent last week. Pittsburgh operations are set at 95 per cent, equivalent to a one point drop. Also down one point is Chicago's rate of 102 per cent. Other declines this week occurred in Philadelphia, down half a point to 91 per cent; Cleveland, down two and a half to 96.5; Wheeling, down three to 95; and Cincinnati down two to 94 per cent. District gains include Youngstown, up one point to 97; Buffalo, up one to 103; St. Louis, up four to 101.5; and the Eastern District, up one to 90 per cent.

As of Jan. 1, 1944, the total capacity of the nation's blast furnaces stood at 67,391,270 tons, nearly 3,000,000 tons above the level of July 1, 1943. Annual steelmaking capacity was increased by 2,771,000 tons during the last half of 1943 and was rated at 93,652,290 tons per year as of the beginning of 1944.

Capacity of open hearth steel furnaces is now rated at 82,223,610 tons per year; that of electric furnaces at 5,350,880 tons; and that of bessemer unchanged at 6,074,000 tons per year. Crucible steel furnace capacity of 3800 tons annually likewise showed no change during the period.

Carbon Steel Cost Study Nears End

Washington

• • • OPA officials expect to complete compilation of carbon steel costs by the end of the present week. They will then meet with the Steel Mill Products Advisory Committee, tell it what the figures show and discuss what action should be taken with regard to price adjustments. Action on carbon steel costs probably will be announced before OPA acts on the alloy steel price study which will parallel that made respecting carbon steel products.

A meeting was held Monday with the Alloy Steel Advisory Committee to get details necessary to begin the alloy steel survey. OPA Administrator Chester Bowles has said that the alloy survey and analysis will not be completed before March.

In response to inquiries OPA has sent out letters saying that the steel costs will not be made public unless the industry agrees to their publication. The figures are confidential and the price law prohibits OPA from making such information public without the consent of the affected industries.

Bright Ray is Believed Sighted in Modernization Needs by Machine Tool Leaders

o o o

By DONALD C. MAC DONALD
Cleveland Regional Editor

o o o

• • • **After much heavy** thinking about saturation of markets and the damaging effects of renegotiation, some machine tool executives have found their thoughts converging recently upon what they believe are basically sound plans for the future.

The current aims of the industry are to modernize the tooling of American industry and quicken the flow of essential tools to manufacturers who will be converted to essential civilian production when military planning has transcended some of its hurdles, the most important of which appears to be the coming invasion.

To point out the need for industrial modernization one observer cites a survey which listed 945,000 machines which were over 10 years old in 1939 and which probably have been used excessively since that date.

Regarding the disposition of the vast number of machine tools produced since 1940, suggestions are being developed which are designed to regulate and ease the movement of these tools into useful and strategic places and which will also foster the best planning of industry in general for solving the economic conditions, soon to be created by reduced war contracts and post-war dislocations, through increased production and employment.

A recent study of the machine tool industry's production in the 1940-43 period-of-urgency indicates that approximately 800,000 tools were built and absorbed by this country and that about 200,000 more went abroad. Those machines which were exported are considered permanently out of this nation's future planning and more than half of the domestic supply are tentatively dispositioned according to various factors.

According to some of the best advised thinking in the industry, about 500,000 machine tools of the original 800,000 built in the war emergency period will be thrown onto the market as idle and excess equipment. Not all of this equipment will come out at once because contract cutbacks and cancellations will provide a slow movement of some portion of these machines during the balance of the war period and continued activity after the war will again suppress a certain percentage from immediate availability on the market.

The services are expected to retain or absorb about 10 per cent of the total in modernizing and refitting arsenals and other strategic production facilities. At least 80,000 of the machines are estimated to be of too highly specialized a nature to find a place in the post-war civilian market. These, if of military preparedness value, are expected to be stored for up to 20 years as a preparedness measure. Trade and technical schools are seen absorbing perhaps 10,000 machines. Russia is expected to require up to 150,000 machines and China and other war torn nations some unestimated small amounts. Estimates of the remaining pool of used but modern machines after these possible outlets have been satisfied run between 480,000 and 500,000 machines left to the American market.

As more than 945,000 machines were 10 years old or older in 1939 it can be seen that any sizable modernization program by industry could readily absorb the bulk of the excess machine tools in the above estimate.

No overloaded market, rife with speculators and bargain prices, is foreseen in that the flow of these machines is expected to occur by degrees. With each progressive stage of the war it is hoped that the military will release unrequired tools for absorption by industry elsewhere. It is also expected that as victory approaches more firms will be permitted to return to civilian production and thereby be in a position to buy equipment and create employment and useful production.

By the slow releasing of military facilities and balancing return to civilian production the gradual movement of equipment could be consum-

SMOKE STUDIES: *A column of smoke (top) testifies to the work of U. S. Marine demolition units on Kwajalein Atoll. At bottom, a Marine corporal toasts a Jap building on Namur with a flame thrower.*

o o o

mated. Cartridge and shell machinery is expected to be the first available and since this takes in a wide variety this first offering to the market should not be hard to move.

The policy which the machine tool industry seems to favor with regard to the pricing of this resale equipment would be to set prices approximating half the list value to encourage quick sales. It has been pointed out that while this appears to represent a heavy book loss to the government, that loss would be quickly offset to the American people by immediate useful production and employment. These machines could under those conditions be absorbed by civilian producing industries and be put to producing material and wages . . . instead of lying idle and in effect opening the door to unemployment and government relief.

Financing of the equipment is favored as a job for the private bank where idle capital and the desire for investment in free enterprise is said now to await only the day of opportunity.

One of the most insistent demands of the industry is that no matter what other provisions are made, the consummation of machine sales must be simple, direct and without limiting "strings" or justification being required to permit purchase. The thought is that anyone who will buy these machines and return to the government that prorated share of its investment should be permitted to do so. The machines though representing book losses to the government are judged to be better sold and in production than total losses and storage problems if held at high and unattractive prices by the government.

It is also projected that machine tool builders might be given a 10 per cent discount from established government prices for the sale of tools to permit purchase for reconditioning and resale through their own organizations. Such a scheme would allow a modest advantage over other purchasers which would permit rebuilding and resale at slightly higher than

Beehive Coke Output Being Curtailed

Pittsburgh

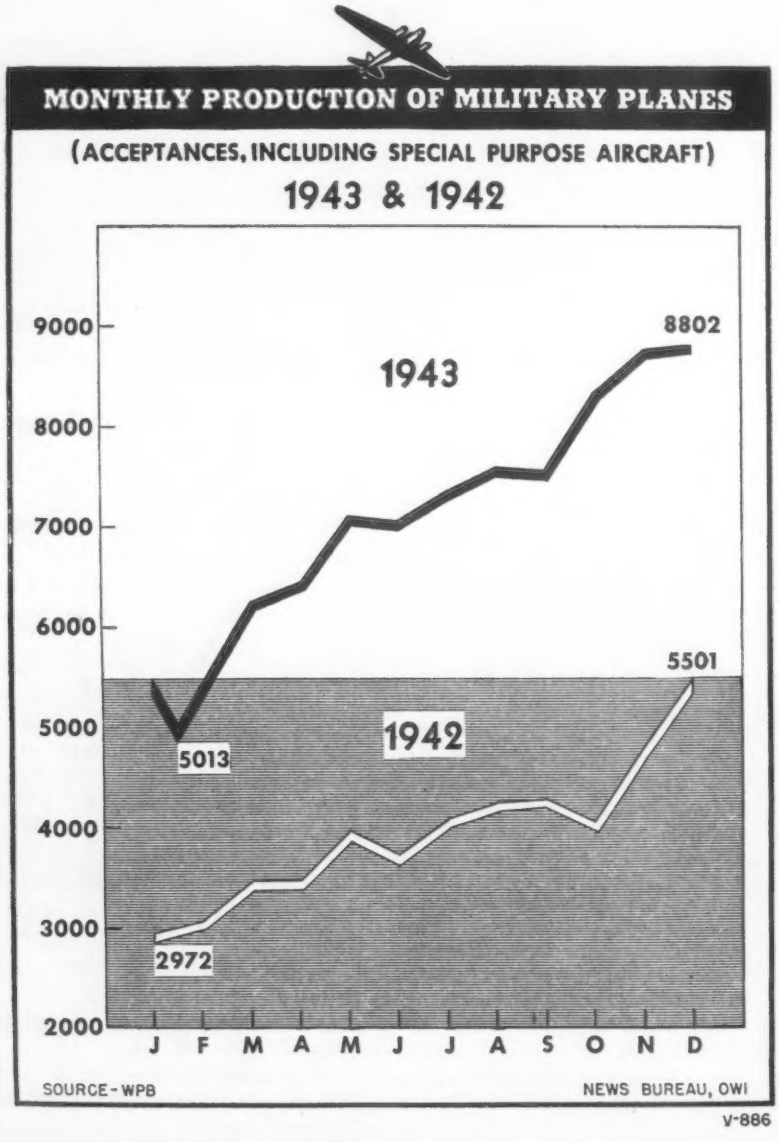
• • • **A falling off** in demand as well as increased production costs, coupled with consumer insistence on better quality, is rapidly resulting in a considerable number of beehive coke plant shutdowns in Western Pennsylvania.

Since the first of the year, it is estimated that about a thousand ovens have been taken out of operation, and hundreds of others have increased their coking time. The H. C. Frick Coke Co., it is understood, has drastically curtailed operations at four of its coke plants, and the number of oven shutdowns at those plants is believed to be in excess of 500.

Early in January, about 480 independent coke ovens had been taken out of operation, and this week about 90 more are slated to go down. High costs engendered by the recent increase in wages, as well as other items, have forced many hand drawn plants out of operation, despite the recent upward adjustments in the price ceiling. Lack of demand, however, has been the major factor in the present trend.

Some coke operators have been hanging on because of demands from the East for heating coke. This outlet, however, will disappear as soon as warmer weather materializes. The fact that many DPC blast furnaces are not operating, and the blowing out of some privately owned stacks for repairs, plus the substantial step-up in by-product coke production, permits the easiest condition in beehive furnace coke since the war began.

There are some observers who believe that within the next several months a considerable number of additional beehive ovens will go out of production, especially those to which coal has been trucked over a relatively long distance. Obviously, those plants, which have been forced to make coke with less desirable coal, will find it difficult, if not impossible, to distribute their coke.



Jesse Jones Gives Views on Decentralization and Stockpiling

By EUGENE J. HARDY
Washington Staff

• • • **Secretary of Commerce** Jesse Jones who came up to Capitol Hill Monday to discuss HR 3873, a bill to give RFC authority to dispose of government surpluses, found himself in the middle of a red-hot argument on the decentralization of America's basic industries, including steel. Mr. Jones, appearing before the House Banking and Currency Committee, talked on stockpiling, government plants and property, industrial decentralization and small business.

The discussion of decentralization of industry began mid-way through the morning session when Representative Rolph, Republican of California, asked Secretary Jones for his views on aluminum plants which had already been shut down because of an oversupply of the metal. Mr. Jones said that he thought these plants should be locked up and kept intact until the war's end and then disposition made of them.

Representative Patman, Democrat of Texas, sponsor of HR 3873, and an ardent advocate of a steel mill in every backyard, asked Mr. Jones what disposal would be made of Republic Steel Co.'s plant at South Chicago, Ill., and the Geneva Steel Co. plant in Utah, and from this point on the hearing centered upon industrial decentralization. Mr. Jones gave no direct answer to Representative Patman's question but did say that "if we could decentralize industry the country would be better off." This would indicate that Mr. Jones speaking for his half dozen bureaus, favored completing and operating the above-mentioned facilities as well as any others which would step up raw materials capacity. Mr. Patman said that steel people in Utah could save $10 to $15 a ton for West Coast users on freight rates alone.

The opposition to dislocating industry was led by Representative Jesse P. Wolcott, Republican of Michigan, who was disturbed by an earlier discussion of a point in subsection (c), Section 205 of the bill, which reads as follows:

"So far as practicable, the sale or lease of such (surplus) property should take into consideration the need for facilitating and encouraging the establishment in the various communities in the several states by members of the armed forces of the United States upon their discharge or release from active duty, as well as by others, of small business enterprises and with a view to strengthening small business enterprises."

A discussion of this section between Secretary Jones and Representative Patman led the Committee to believe that this bill would give the Government the power to move any of its facilities to any section of the country if a buyer could be found. The implication was also made that if buyers could not be found the government would operate these plants to achieve the purpose of making each section of the country self-sufficient in time of war.

At this point Mr. Wolcott said he was tired of a "managed economy" and that he was behind the bill until he saw that under the provisions it might be possible for the government to manipulate American industry as it desired. He asked whether the Federal government would be given authority to manipulate the location of industrial plants in the provisions of the bill. Mr. Patman replied that if there was no market for the plant in the area in which it stands, then someone in another area should be given the right to buy.

Mr. Wolcott was particularly displeased with the language "so far as practicable." He said he was tired of Congress enacting such vaguely worded legislation and then leaving the "practicability" up to some government bureau. He said that too much leeway was given under this type of legislation, citing OPA as an example. Mr. Patman countered this by saying inelastic legislation was too restrictive.

The Michigan representative said that power to move the steel industry from Pittsburgh to Utah would not only mean a movement of plants, but of people and would cause general disruption. He said that he thought it would be more economically sound to scrap excess factories, rather than move them all over the country. Secretary Jones had previously said that he favored moving such government-owned plants, if they were economically undesirable where they were located. Mr. Wolcott, addressing Mr. Patman, said he thought the bill was to dispose of surplus goods, eliminate speculators, etc.

At this point Representative Ford, Republican of California, in one of his dramatic renditions said that the Pacific Coast was dependent on a Pittsburgh-managed steel economy and that the "United States Steel Co." has managed the steel economy of the United States. He concluded by saying: "We've got steel plants and now we're going to keep them." This statement was greeted by a round of applause from a serviceman in the audience, to whom Mr. Wolcott replied the power to move a plant into a state would also be power to move another plant out of the state into which the first plant is being moved.

In closing this discussion Mr. Rolph commended Mr. Jones on his opinion that the Geneva Steel Co. facilities be completed.

Price Differentials Set on Rail Scrap

Washington

• • • Specific dollars and cents differentials that may be applied to the maximum price for No. 1 railroad heavy melting steel scrap by railroads, car manufacturers, and switching companies to determine their ceilings for 35 listed grades of railroad scrap were established this week by OPA in an amendment to revise price schedule No. 4.

The formula method of pricing grades other than No. 1 heavy melting, under which ceiling prices were the highest prices individual sellers charged during the base period of Sept. 1, 1941, are replaced.

The differential pricing method supplies sellers with specific additions and deductions that may be applied to the ceiling for No. 1 scrap in 29 basing point cities. The differentials set ceiling ranging from $6 a ton over the base to $6 below the base price, according to grade.

Also an increase in dealer's fee for preparing heavy breakable cast iron scrap for foundry sizes from $2.50 to $3.50 per gross ton was announced. There was also an increase of $1 per gross ton in dealer's fee for in-transit preparation.

Because the new price ceilings were not received in time to adjust the price schedule on the following page, such changes will be made in the issue of Feb. 24.

Briefly Told—

Cancellation Makes 4600 Tons of Steel Available at Detroit

• Approximately 4600 tons of shell steel has been made available at Detroit through the WPB Materials Redistribution branch as a result of a contract cancellation. The steel is in 3¾ in. rounds from 15 to 22 ft. in length. Analysis is 0.50-0.59 C; 0.69-0.98 Mn; 0.055 P; 0.06 S; 0.15-0.35 Si.

•

• Companies interested in obtaining surplus materials and equipment being offered for sale by the Army Air Forces and who are desirous of being placed on the active bidders' list, should write to the Army Air Forces, Material Command, Midcentral Procurement District, 111 West Jackson Blvd., Chicago 4, Attention of Redistribution and Salvage Section, according to an announcement by the section.

•

• *C. D. Howe, Minister of Munitions and Supply, stated that Canadian shipyards are to enter upon the construction of a number of large steel landing barges, the first of this type of craft to be built in Canada although smaller craft of this nature have been produced in hundreds. Orders for the large steel landing barges have been placed with Yarrows Ltd., Victoria, B. C.; Davie Shipbuilding & Repairing Co. Ltd., Lauzon, Que., and Canadian Vickers Ltd., Montreal.*

•

• Leo T. Crowley says his alien property office has seized control of property valued at $375 million plus 41,000 patents and patent applications.

Business enterprises taken over by the custodian totaled 318 and about 200 of them, principally trading companies, banks and insurance companies, are being liquidated. Approximately 100 are being continued as going concerns and will be sold to private interests through competitive bids.

•

• *Canadian control boards are lifting restrictions on the use of iron, steel, metals and other materials to enable larger production of civilian goods. Wartime Prices and Trade Board has taken action to make available certain metals for the manufacture of builders' finishing hardware, cabinet locks and padlocks. Releases of nickel, silver, ingot brass, secondary aluminum and secondary zinc from the restrictions will permit the manufacture of some items previously prohibited.*

•

• The Missouri Supreme Court has held that the 2 per cent sales tax does not apply to interstate retail sales in three test cases, one by the American Bridge Co., the other two by the Binkley Coal Co. The ruling, which declared invalid the attempts of State Auditor Forrest Smith to levy the tax on interstate sales, applied directly to about $500,000 in sales taxes impounded in court at Jefferson City, Mo.

•

• Stainless steel will remain the principal structural material in railroad passenger cars constructed by Edward G. Budd Mfg. Co. in the postwar period despite increased availability of aluminum, company officials say. Aluminum will be utilized for interior trim, car seat components, and other non-structural accessories because of its light weight, but basic structural members, including the "skin," will still be of stainless steel construction.

•

• *As a result of increased demand for electric fence controllers, the industry will have in the 12 months ending June 30, 1944, produced a substantially greater quantity of these devices than in any previous year, according to WPB. These devices, which permit slight electric impulses to be transmitted through fence wire at determinal intervals, aid stockmen to confine cattle to enclosed areas.*

•

• The American Hot Dip Galvanizers' Association will hold its annual meeting at the Blackstone Hotel, Chicago, on Feb. 24 and 25. Attendance will be by invitation. Representatives of the Zinc Division, WPB, and the Conservation Division, WPB, will be among the speakers. E. V. Gent, Zinc Institute, F. W. R. Pride, of the Navy Price Adjustment Board, and A. T. Baldwin, of the Hanson-Van Winkle-Munning Co., are also slated to talk. Stuart J. Swensson, American Bank Building, Pittsburgh, is secretary of the Association.

• *Iron ore production in the United States in December totaled 3,656,268 net tons, while stocks at the end of December were 34 per cent greater than at the end of November, according to the Bureau of Mines.*

•

• The Gray-Mills Co., manufacturers of portable coolant systems for metalworking industries, has moved from 215 W. Ontario Street, Chicago, to a new plant at 1948-52 Ridge Avenue, Evanston, Ill. The new plant, a two-story structure containing 50,000 sq. ft. of floor space, more than doubles space formerly used for manufacturing, warehousing and by the engineering and office personnel.

•

• *The Lockheed Aircraft Corp. last week disclosed the invention of a new machine designed to set from 33,600 to 75,000 rivets an hour.*

•

• A manual of preparation for war contract termination was issued Feb. 12 by the National Association of Manufacturers, New York, for the guidance of its members. Meanwhile, in Washington, the U. S. Army (Readjustment Division of the Army Service Forces) is reported to be rushing to complete a manual on the problems of contract termination.

•

• *The American Brake Shoe Co. has issued the third of its good-will books. This one is entitled, "Your Son and Ten Fighting Generals." It is written by Donald Wilhelm. The theme is that "the fate of your boy, mine and millions of others, is directly in the hands of ten men—Gen. Marshall and the nine other generals in command of our war theatres and armies."*

•

• Through inventories set up in the WPB regional offices, 12,728 items of used construction equipment were supplied for construction jobs in 1943. These items are valued at $64,000,000 and represent a saving of approximately 126,000 tons of raw materials, since they were used in place of new equipment, 90 per cent of which is said to be needed overseas.

•

• *In December, 1943, when he resigned as chairman of the board of the Pittsburgh Steel Co., Henry A. Roemer, according to a SEC report of recent issue, disposed of all of his stock holdings in that company by the sale of 20,222 common shares. He increased by 4700 his former total of 4683 shares of common stock of Sharon Steel Corp., it was disclosed, to a total of 9383 shares, and his ownership of Sharon Steel preferred to a total of 1,065 shares.*

Labor Plays Key Role in Output Of Foundries Affecting Merchant Iron

New York

• • • **The continued high** production of merchant pig iron throughout the eastern and midwestern parts of the nation seems to hinge primarily on the ability of foundries to produce up to their order books.

Labor in the foundries is the present hampering factor to casting production and is becoming continually more serious. Gossip in the trade has it at present that draft boards in the western Pennsylvania-eastern Ohio areas are trying to get molders, pourers, and other skilled foundry help on a preferred list so that the drain on manpower in this industry will subside. Newcomers into the field are few, mainly because of the dirty, backbreaking work at not too high a pay rate. Orders are and have been well ahead of iron foundry output.

Following the cessation of allocation of pig iron, orders through the first quarter of 1944 took a sudden spurt upward. However, one of the difficulties of going from a free-commercial to a government regulated and back to a free-commercial method of doing business became immediately apparent following the cessation of allocation of iron. While iron was allocated, consumers ordered on a monthly basis and, if the allocation was approved, received specified tonnages each month. However, the normal method of doing business in merchant iron was to order on a quarterly basis, specifying monthly shipments. Consequently, during the first quarter, iron producers continually had to keep in touch with consumers to determine what individual monthly shipments were desired. With the limited types of merchant blast furnace products available, this may be an indication of what can be expected when there is a wholesale changeover on other lines of production.

Merchant furnaces probably will start opening order books for second quarter bookings within the next two weeks, but furnaces are generally sold out through the first quarter.

o o o

Founders Advised to Adjust Certain Operating Policies

Chicago

• • • **Provided** certain operating policies are overhauled, a brilliant future lies ahead of the foundry industry through technological advances, John H. Van Deventer, president and editor of THE IRON AGE, told the Chicago Chapter of American Foundrymen's Association last week.

Development of alloy irons and of heat treatment indicate that disadvantages of gray iron, because of lesser strength and shock resistance than competing materials, are being overcome. Certain progress in centrifugal casting, development of the use of permanent molds, particularly for non-ferrous centrifugal castings, and other precision casting processes rapidly developed during the war were credited with greatly advancing the industry.

Foundries were urged to follow the lead of the steel industry and shape merchandising and production in accordance with customer needs, particularly with metallurgically tailored castings. This step, Mr. Van Deventer said, would enable foundries to break the shackles of limited sales territories caused by freight rate considerations. An expanded market and technical research program will be necessary to push forward this specialization, he declared.

Refinement of cost accounting systems was said to be a basic necessity in order to put many foundries on their feet financially, and thus enable them to serve their customers efficiently.

"Cooperative research utilizing the wonderful laboratory facilities and personnel of our great universities is essentially practical for your industry," Mr. Van Deventer said.

As a corollary, he urged the foundries to actively recruit new engineering and technological talent, lack of which he classified as a current "vitamin deficiency" for the industry.

Malleable Casting Output at New High

• • • **For the second time during 1943, malleable iron casting production passed the 75,000 net ton mark in December, when 75,188 tons were produced. This made the year's output 849,764 net tons a new annual production record for malleable iron castings. Issued by the U. S. Department of Commerce, statistics on malleable iron castings for 1943 and for the last four months of 1942 were compiled from returns of 103 manufacturers with 113 plants.**

	MALLEABLE IRON CASTING PRODUCTION, NET TONS				
	December, 1943	November, 1943	1943	1942	1941
PRODUCTION, TOTAL	75,188	72,077	849,764	768,496	843,038
For sale to outside trades	57,744	54,640	654,524	607,610	630,800
For use by own company, or that of an affiliate, subsidiary, or parent company	17,444	17,437	195,240	160,886	212,238

Monthly index of production *	187.1	179.4	176.2	159.4	174.8

*Based on average monthly production (40,181 tons) for the five year period 1935-1939.

Hanna Shuts Down Furnace

Buffalo

• • • **Attributing the** situation to a decline in general foundry demand for merchant iron, Hanna Furnace Corp., Buffalo, shut down a 500-ton blast furnace Feb. 10. Three furnaces remain in production.

USWA Inaugurates Its Own "Mustering Out" Pay System

Pittsburgh

• • • **Cognizant of the** actual and potential weight of opinion which the armed forces hold with respect to events along the home front, the United Steel Workers of America-CIO has proposed that if steel labor is granted a wage increase the workers shall contribute $20 per person and the steel companies a like amount, for a joint fund which will be paid out to steel workers in the armed forces when they are mustered out.

The resolution enacted upon by the union's national wage and policy conference, held in Pittsburgh Feb. 11th, authorizes the union to submit to the WLB, as part of the case which it now has before the board, in the form of wage requests, etc., the following proposal:

1—In case of a wage increase, steel workers to contribute out of this $20 per worker.

2—Steel companies to be directed by WLB to match employee contributions.

3—Contributions to be pooled into a single joint fund which shall be paid out to steel workers in the armed services when they are honorably discharged, or to dependents of those killed in service. The pro-ration to be on the basis which will allow a certain amount to each soldier, depending on his length of service both in this country and overseas.

4—The program to be under the supervision of trustees to be named by steel companies and the union.

With the union claiming about 700,000 members, and if a wage increase were granted, and if all these employees contributed $20 and if the steel companies matched this contribution, the pool of money for distribution to men in the armed services would approximate $28,000,000, or an average of about $140 for each steel worker in the services. No comment from steel sources on this program was available here, and it is now in the lap of the WLB.

Labor Shortage Eases

• • • A decrease in absenteeism with an easing in the critical labor situation and a generally better production outlook is reported from New England manufacturing centers other than the Boston area. One reason is that thousands of women workers who were chronic absentees have dropped out of industry, having found that keeping abreast of both home and war work is impracticable.

Allister R. Tullock of the Employers Association of Western Massachusetts says industrial plants in the Springfield area have reached a peak of employment, although there are some that still need help, particularly common labor.

o o o

Boston Placed on 48-Hour Week

Boston

• • • **With virtually** all essential industries operating on a 48-hr. weekly basis, the Boston area was officially placed on that basis by the War Manpower Commission and War Production Board. Business admits any benefit will not result immediately; that it will take time to squeeze labor out of small into big plants; and perhaps the ultimate result of the action will hurt business in general in the long run.

A voluntary suspension of hiring by all non-essential and not locally needed business in the Boston area will probably be asked. It is hinted that if this suggestion is made and not followed, Washington will slap the 48-hr. week on all industry and business.

The largest essential Boston war industries are firing rather than hiring help. Their help wanted advertising has been cut or abandoned, and those few essential industries advertising for help are either comparatively small or want women and girl workers only. Investigation shows that 80 per cent of help wanted newspaper advertising is by non-essential firms calling for a class of help hardly suitable for war work.

Boston essential war industry women workers comprised 30 per cent of all employees, but in the past six months have dropped to about 26 per cent. This fact, coupled with the estimated 15,000 men to be inducted between Jan. 1, last, and next June 30, is intimated to have been considered by the WMC before making its Boston area 48-hr. week decision.

VILLAGE SMITHY GOES TO WAR: *Process of fabricating parts of phantom or magic decks in the shop and installing them atop merchant cargo vessels and tankers has resulted in Greenwich Village blacksmith shop expansion, with 10 plants and storeyards now in use. Idea enables safe transport of planes, whole railroads, invasion barges in sections and PT boats. School children watch 68-year-old Joseph Yellen at his work.*

Pittsburgh Establishes "Manpower Budget Plan" to Combat Labor Shortages

Pittsburgh

• • • **On March 1** a male employee job rationing plan said to be composed of the good points of plans now in effect throughout the country, will become effective in the Pittsburgh area. This plan is to forestall the imposition of a mandatory 48-hr. week and the placement of Pittsburgh in the Group 1 Critical Labor status.

According to the WMC here, hiring of women will remain unrestricted except that those in essential activities cannot shift jobs without first obtaining a statement of availability.

The rationing program, to be known as the Pittsburgh Manpower Budget Plan, was adopted by a unanimous vote of the Labor-Management Committee, and imposes drastic control over employment activities not considered essential or locally needed. Employers in the Pittsburgh area will be divided into three classifications:

Group 1—Those with direct Army, Navy or Maritime contracts will be permitted to hire men for both replacement and expansion needs.

Group 2—All other employers whose activities are considered essential or locally needed will be allowed to hire men for replacement only.

Group 3—Non-essential employers who will be permitted to hire only women, veterans, boys under 18, part time workers available for no more than 30 hours of work in any seven day period, and 1-A draft registrants awaiting induction. Other than that, employers in this group, which includes department stores, restaurants, taverns, etc., will be permitted to hire only through the U. S. Employment Service.

Groups 1 and 2 employers will be able to do private hiring in accordance with the regular rules covering "releases" under the employment stabilization plan. The WMC area director here, Patrick T. Fagan, has by letter warned Pittsburgh area employers that numerous instances of violations in hiring employees, without fullfilling the proper terms under which statements of availability are granted, have come to his attention.

A committee representing agencies such as the WMC, WPB, the Army, etc., has been named, and will rate employers on a priority basis for the purpose of filling vacancies as well as establishing employment ceilings. It is expected that half of the industry in the Pittsburgh area will come under either Group 1 or Group 2. Steel companies, it is believed, for the most part will come under Group 2, unless a portion of the plant or a plant is working specifically on direct contracts from the Army, Navy, or Maritime. Shipbuilders here will be Group 1.

Labor observers here have noticed that non-essential activity appears to have had little difficulty in obtaining new employees, while certain jobs in essential industries have gone begging. While the Pittsburgh area does not appear to have a "numerical" labor shortage, there is a severe shortage of men for certain jobs in essential industries or a shortage of employees willing to take these jobs.

With non-essential activities being forced to clear their employment needs through the USES, except when women, young boys, or veterans are hired, it is believed that a better control over available labor will result.

The Pittsburgh area for which the plan will become effective applies to Allegheny and Beaver Counties, New Kensington, Vandergrift and Monessen districts of Westmoreland County, the Charleroi sector of Washington County, and the town of Belle Vernon in Fayette County.

o o o

Frazer Buys Warren Plant

Cleveland

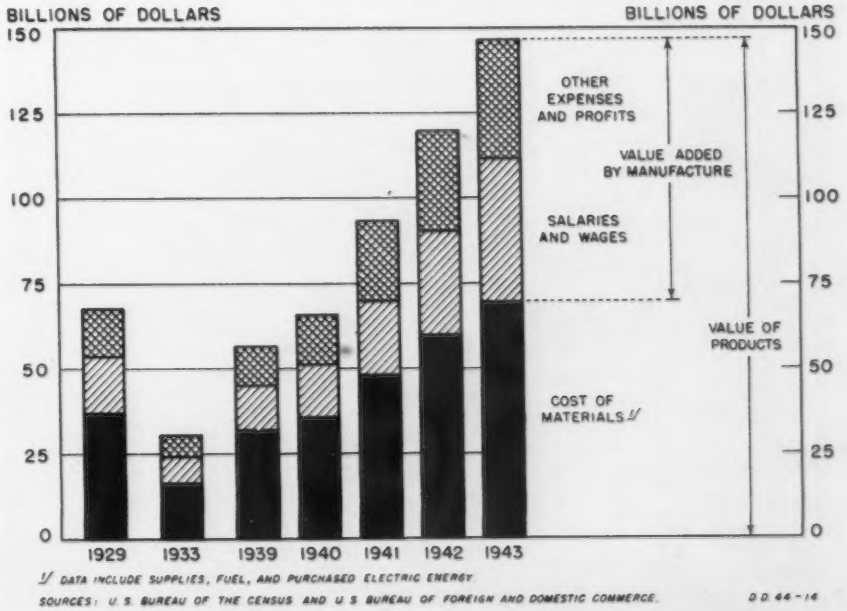
• • • **Joseph W. Frazer,** former president of the Willys-Overland Corp. and executive of the Chrysler Corp., announced to THE IRON AGE on Feb. 15 the completion of the transaction transferring certain assets of the Warren City Tank & Boiler Co., of Warren, Ohio, on Feb. 13, to his newly organized Warren City Mfg. Co. The plant will continue to produce for the Navy as it has in the past and will employ 1500.

Officers of the new company are: Frazer, president; W. A. MacDonald, vice-president and field manager; Raymond J. Fitness, vice-president in charge of manufacturing; Marvin J. Ales, vice-president and treasurer; Erwin Ilg, assistant secretary.

The assets purchased in the transaction include accounts receivable, inventory and certain fixtures. About $10,000,000 is reported to be on the books of the company, according to Frazer. The plant will continue to make landing barges, boilers, diesel engine crankcases, reduction gear cases for ships, and other products for the Navy Bureau of Ships.

Rear Admiral C. L. Brand, U. S. N., chief of the shipbuilding division of the Bureau of Ships, said, "We are confident that under Mr. Frazer's management the Warren City plant will continue to improve its production record."

VALUE OF PRODUCTS OF MANUFACTURING INDUSTRIES



Manufacturer Responsible for Delivery under New Scheduling Method

Washington

• • • **Scheduling procedures** designed to bring about greater utilization of available productive facilities, have been adopted by WPB. During the past year, scheduling controls have been implemented by WPB under rigid rules, requiring manufacturers to file detailed order sequence reports with the various WPB Industry Divisions. As a result of this experience, it is now possible to center controls in the hands of the manufacturers themselves.

Major purpose of the shift in scheduling controls is to center responsibility for meeting delivery requirements of specific components and parts in the hands of manufacturers as far as possible. Items affected are those common to more than one (in some instances, many) war production programs. The new scheduling procedures are spelled out in General Scheduling Order M-293, as amended Feb. 10, 1944. This order (1) modifies procedures in connection with Class X products, (2) includes specific provisions with respect to undesignated products, and (3) eliminates the Class Z product designation and rules which have governed scheduling of them.

Manufacturers of Class X products must continue to file delivery schedules with WPB unless specifically exempted from doing so. In all practicable cases, manufacturers will be excused. Only cases where delivery schedules are consistently out of line with actual delivery needs or where considerable adjustment of schedules is necessary due to changing requirements will be viewed by WPB as requiring continued WPB supervision. In either case, the Class X product manufacturer's schedule will be frozen.

This will give most manufacturers of Class X products the authority to freeze their own delivery schedules as of a specific date each month in line with general WPB rules. This date will vary from manufacturer to manufacturer, and will be indicated in the letters sent from WPB excusing them from filing reports of their delivery schedules. Delivery schedules of those manufacturers who will be required to continue filing will be frozen as of the date the schedules are mailed to the WPB.

Frozen delivery schedules are those which may not be interfered with unless on specific authorization of the WPB. This means that the delivery sequence may not be upset and that production necessary to meet that sequence may not be interrupted to meet deliveries for other products.

Class Y product scheduling procedure has not been modified although the number of such items will be reduced. Persons desiring to purchase Class Y products are still required to obtain a specific authorization from WPB to purchase them as well as authorization for manufacturers to accept their orders. Delivery schedules for Class Y products become frozen schedules as of the time orders for them are accepted by the manufacturer.

Undesignated products are those on which delivery schedules must be filed by specific manufacturers at the direction of WPB. This procedure has been in use for some time.

Individual manufacturers of undesignated products will be instructed by WPB that they must file delivery schedules. However, other manufacturers of these products may file the appropriate forms which will now be specified in order M-293, although the schedules will not be frozen until WPB so directs.

WPB has reserved to the War Department, Navy Department, Maritime Commission, Office of War Utilities, and the Petroleum Administration for War and the Canadian Division for similar programs the right to require statements of delivery requirements in connection with the products which are affected insofar as the principal war production programs are concerned.

"WASP WAGON"—*Packing four .50 cal. machine guns mounted on the top, this half-track is the Army's newest mobile weapon, according to the Cleveland Ordnance District. Capt. T. O. Girdler, son of Republic Steel Corp.'s board chairman, mans the unit.*

Railroad Gages Standardized

Washington

• • • **To provide for** the standardization and simplification of railroad gages which are specially designed and manufactured for use on locomotives and railway rolling stock, WPB issued Schedule 8 to Order L-272. This action represents a further step in the program of standardization of industrial type measuring instruments that has been conducted over a period of several months by the issuance of various schedules under the existing order.

Order M-21-g Clarified

Washington

• • • **To clarify** an anomalous situation in connection with the materials control provisions covering the manufacture of conveying machinery and mechanical power transmission equipment which arose through the revocation of Order M-21-g, WPB issued an amendment to L-193. The amendment permits producers of such equipment to use alloy steel or iron in chains and sprockets of conveyors and elevators.

CMP Revision Permits Use of Surplus Stocks in Other Schedules

Washington

• • • **WPB has clarified rules** governing the use of controlled materials after they are received by a manufacturer. The clarification was made by an amendment to CMP Regulation No. 1, which deals with basic CMP allotment procedure.

The amended regulation permits a manufacturer to use surplus material to fill another authorized production schedule than the one for which the material was originally acquired, if he changes the original allotment account. Formerly, a manufacturer could only use such material to fill another authorized production schedule if the other schedule was identified by the same claimant agency letter symbol.

The amended regulation states that a consumer of controlled materials may keep such materials and Class A products received in a common inventory. In withdrawing from this inventory, he does not have to charge these products or materials against his allotment account.

Manufacturers operating under several production schedules do not have to maintain separate records for each schedule, if their usual records indicate that the production on each schedule is substantially in proportion to the amount of the allotments received for each schedule and that their aggregate production of any product does not exceed the aggregate of the production schedules authorized.

Consumers of controlled materials must charge their allotment accounts with materials acquired under Priorities Regulation 13, unless that regulation indicates that such a charge is unnecessary. In certain instances, WPB regional offices are permitted to allow the allotment purchase of controlled materials, under provisions of Priorities Regulation 13.

The modified CMP Regulation No. 1 requires that consumers check on allotments the first of each month, and if they have been allotted more controlled materials than needed, returns of the excess must be made by the tenth of the same month. At the end of each calendar quarter, a consumer must determine whether he has used his entire allotment by placing authorized controlled material orders or making allotments to secondary consumers, and, if he has any excess, regardless of how small it is, he must return it by the tenth day after the close of the quarter. Minor changes are made in the symbols designating claimant agencies. In addition, the list designating controlled materials has been spelled out in greater detail, indicating more specifically what materials are in the different categories.

Bearing Users Acceptances Restricted until Sept. 30

• • • **WPB ordered** that users of anti-friction bearings may not accept deliveries in excess of specified amounts during any one month of the 2nd and 3rd quarters of 1944 without specific approval. This action was taken in a move to relate the actual needs for such bearings to the supply, and to assure that statements of delivery requirements are realistic.

Direction No. 1 to table 12 to order M-293 provides that without specific WPB authorization no persons shall accept from either a manufacturer or a distributor, during any one month between April 1 and September 30, 1944, any anti-friction bearings in excess of: 1—Fifteen hundred bearings of any one size where they are being purchased for incorporation in an end-product or for reshipment with the end-product as concurrent spare bearings. 2—Five hundred bearings of any one size where they are being purchased for reshipment to the Army, Navy, Maritime Commission, or the War Shipping Administration subsequent to delivery of the end-product. For example, this would include bearings bought for the purpose of filling contracts for "second year replenishment" bearings and for similar supplemental spare bearing requirements ordered by the procuring service.

Bearings of one size used during a month in amounts less than those specified need not be reported. These restrictions on acceptance of bearings apply on a plant basis, and if one producer has more than one plant, the limits apply to deliveries to each plant.

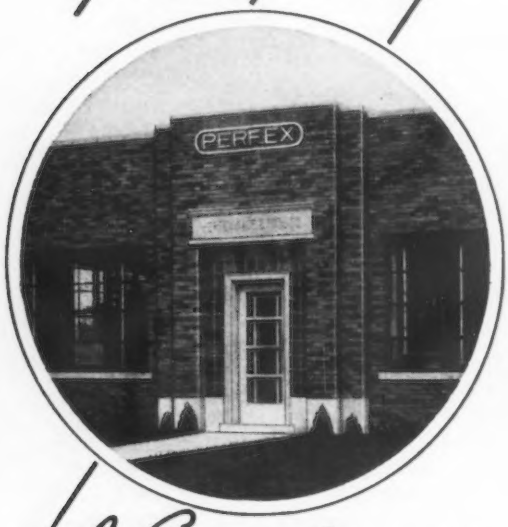
Approval to purchase anti-friction bearings may be obtained by filing WPB Form 3333. This form should be filed before March 1, indicating bearing requirements for the two succeeding calendar quarters.

In filing Form 3333, users shall (1) state delivery requirements, for those bearings used in sufficient amounts to require reporting, from April through September, 1944, inclusive, and (2) finished product schedules for April through December, 1944, inclusive.

Some users were requested in a letter dated Jan. 7, 1944, to indicate delivery requirements from March through August, 1944. They will continue to make applications to receive anti-friction bearing deliveries as were instructed in the letter. However, persons who submitted requirements for anti-friction bearings on the original WPB Form 3333 of Oct. 22, 1943, according to WPB's telegram of Oct. 28, 1943, will be required to follow the new procedure.

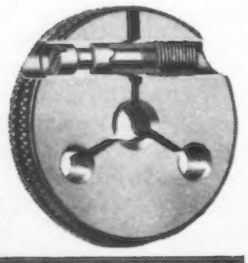
NOT FOR SCRAP DRIVE: *This badly damaged Lancaster is being reconditioned at a British aircraft factory. Repairs are made quickly so that the bombing of German cities continues on an uninterrupted schedule.*

The Home of Accuracy



THE HOME of PERFEX Gages is the home of accuracy, because in this modernly designed and equipped plant accuracy has become a creed. A creed that only skilled men with years of making precision gages can adhere to.

It is by this adherence to accuracy that PERFEX has gained an enviable reputation among manufacturers who demand the best in precision built gages



Perfex manufactures plain plugs, plain rings, thread plugs and ring thread gages. For delivery dates and prices wire or write us today.

WPB Administers Tax Amortization

Washington

• • • **Carmen Blough,** head of the WPB Facility Amortization Division, said that there has been a great deal of misunderstanding of the Executive order of Dec. 17 transferring the administration of tax amortization laws to WPB.

Many industries have interpreted the order as an invitation to once again apply for certificates of necessity at a comparable rate which they did when the government first adopted the policy of encouraging the private financing of defense plants.

Mr. Blough said that the contrary is true, and that all applications for certificates are being reviewed in the light of the requirements that (1) facilities to be constructed or acquired are clearly necessary for the war effort and (2) that it is to the advantage of the government that such additional facilities be privately financed.

Consequently, under current policy, certificates are being granted in a minority of cases, inasmuch as the government war construction program is largely completed and many facilities are in existence which are available for most war needs, it was pointed out.

The advantage tax amortization gives, Mr. Blough said, nearly amounts to a government grant of the facility since the five year privilege on the average equals 91 per cent of the value of most plants built under certificates of necessity. Certificates of necessity to value of $5,500,000,000 have been issued according to the latest War Department tabulations.

Republic Issues Steel Manual For Latin American Countries

• • • **A 98-page book,** "The Story of Republic Steel," is being distributed to buyers and users of steel in all Latin American countries. It is available in English, Spanish and Portuguese editions. In addition to telling the story of how steel is made, it offers much technical information on many different types of steel, steel products and steel applications for the guidance of purchasers and fabricators outside the United States.

One chapter deals with the forms, finishes and sizes of well-known specialty products in steel. Definitions of iron and steel terms are collected for Latin Americans in another part of the book.

PRODUCTION UP COSTS DOWN

with Titan Hot Pressed Parts

Intricate shapes, thin sections, dimensional accuracy. No sandpits, blowholes or sand particles to impair machining or cause failure under stress or strain. Easy machinability with minimum scrap keeps cost of finished parts down. Titan's faultless machining delivers finished parts all ready for your assembly, or you can do your own machining if you wish. Advanced metallurgy, engineering skill, craftsmanship in manufacturer, personalized service, promptness—all are available from Titan. Experts in non-ferrous metals for over a quarter of a century.

Titan will deliver them finished if you wish

Priority Changes

L-42—Sched. VIII eliminates simplification and standardization requirements in the manufacture of radiator supply valves, low pressure thermostatic radiator traps, combination float and thermostatic traps and boiler return traps. (2-8-44)

L-106—Order restricting use of copper for certain automobile parts has been revoked. Other copper orders (L-158 and M-9-c) remain in force. (2-12-44)

L-193—Amended order permits conveying machinery and mechanical power transmission equipment producers to use alloy steel or iron in chains and sprockets. (2-11-44)

L-248 amendment permits use of iron and steel frames in luggage for civilian use, as well as the use of iron and steel slide fasteners. Also packing trucks are added to luggage permitted made for civilian use.

L-269—Amended order relieves mining equipment manufacturers from filing monthly reports on schedules for 40 items of equipment. Required to submit report at any time, should such report be deemed necessary. (2-7-44)

L-292—Sched. VI and VII set percentages covering the gross tonnages of controlled materials manufacturers may use in production of meat canning, processing and packing machinery and equipment, and quota percentages covering the production of flour, grain, and feed milling and processing machinery equipment. (2-11-44)

L-303—Amdt. 1 rules that preference ratings of AA-3 or less on civilian purchase orders for steel insect screen cloth be disregarded, to provide equitable distribution of this product for civilian use. Such orders are now to be treated as unrated orders. (2-11-44)

L-318—Standards for manufacture of spot welding electrodes revoked. (2-7-44)

M-6-c—Report forms for nickel scrap and secondary nickel have been revoked. (2-9-44)

M-9—Amended order removes flake type bronze powder from definition of copper and copper-base alloy powders for which it has heretofore been necessary to obtain authorization to receive deliveries. (2-11-44)

M-9-c—Amended order provides that insect screening not purchased by Metals Reserve Co. or Copper Recovery Corp., except when rejected as not meeting specifications, will be subject to prohibition of delivery cutting or installation of the material. (2-12-44)

M-21—Amended order excepts cast iron soil pipe and fittings from prohibition on delivery of iron products except on rating of A-10 or better. (2-7-44)

M-293—Dir. 1 to Table 12 provides that users of anti-friction bearings may not accept deliveries in excess of specified amounts during any one month of the second and third calendar quarters of 1944 without specific approval. (2-9-44)

M-369—Amended order gives producers of tungsten, molybdenum, and their alloys opportunity to unify production schedule. (2-8-44)

P-55-c—Order provides simplified procedure eliminating filing of material lists for privately financed housing construction and permits use of additional materials to conserve lumber and fuel. Order effective March 1. (2-12-44)

Dir. 7 to PR 3 governs replacement of defective material or material lost, stolen, destroyed or damaged in transit when rated orders were placed for it. (2-8-44)

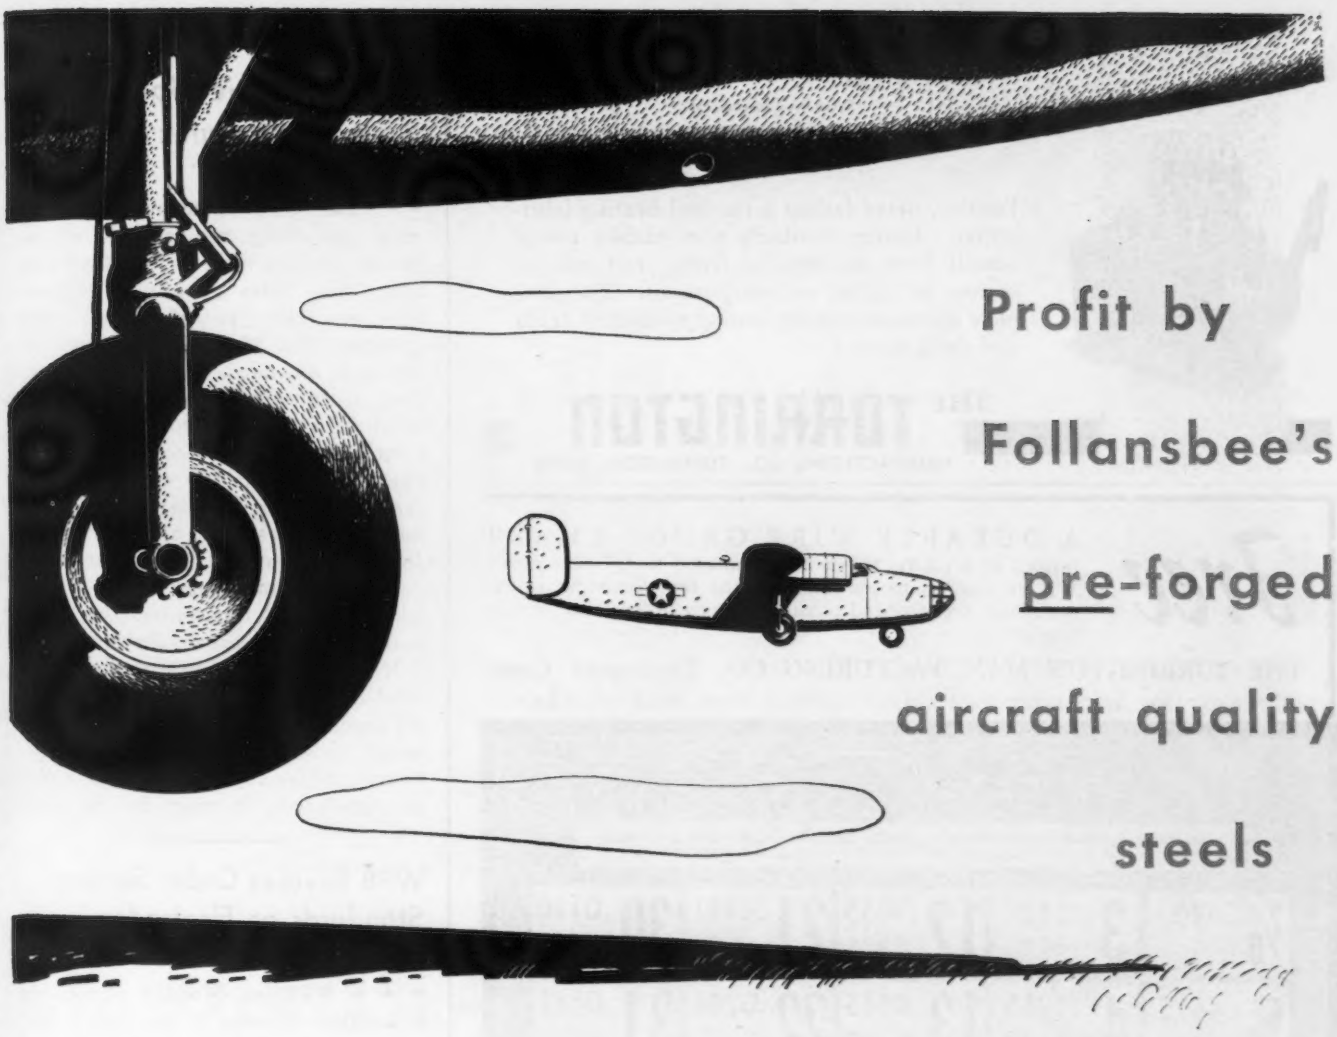
Dir. 1 to PR 11B provides procedure under which manufacturers of one product, part of the output of which are Class B products and the rest of which are unclassified products, may file a single CMP-4B application to cover the entire production of the item. (2-11-44)

CMP Developments

● Dir. 2 to Reg. 6 indicates that rules previously governing housing construction no longer apply inasmuch as Limited Preference Order P-55-c now governs. (Release No. WPB-4973)

●

● Sched. III to Reg. 1, amended to include the time for placement of authorized controlled material orders for copper and aluminum. (Release No. WPB-4930)



Profit by Follansbee's pre-forged aircraft quality steels

An important aircraft equipment manufacturer says, "Our tests show your steel to be the highest quality for aircraft service . . . we are approving your basic open hearth steel, aircraft quality, as an alternate for standard electric furnace steel of aircraft quality."

Follansbee alloy steels are winning such recognition through the exclusive PRE-Forging process—the pressing of ingots into blooms or billets, resulting in a more homogeneous structure than rolling can impart. Small basic open hearth furnaces under close, skillful control is another important factor.

For the tough jobs of today and tomorrow which call for high quality alloy steels, you can profit by specifying Follansbee PRE-Forged steel.

Stainless Rejection Rules Modified

Washington

• • • **The WPB announced** amended rules governing replacement of rejected stainless steel so that they conform with rules governing replacement of other types of steel. Under Direction No. 16 to CMP Regulation No. 1, as amended, Feb. 1, this means that with certain exceptions when stainless steel is rejected by a customer because of non-conformity with specifications or for other reasons, the producer must make the replacement in preference to all other orders for similar material. However, WPB or the customer may give specific instructions to the contrary, without seeking an additional allotment.

If any portion of rejected stainless steel can be used by the producer to fill another authorized controlled material order or for permissible delivery under any other WPB order or regulation, it may be so used.

WPB Revokes Order Setting Standards on Electrodes

Washington

• • • **WPB on Monday** announced revocation of order L-318, which had set standards for the manufacture of all spot welding electrodes. Upon investigation, WPB said, it was found that the standards prescribed under the order were not readily adaptable to the types of resistance welding equipment used in most aircraft construction. Manufacturers of electrodes are now free to produce any types required by their purchasers but will continue to function under the applicable CMP regulations covering their industry.

Cast Iron Soil Pipe Freed Of WPB Delivery Restrictions

Washington

• • • **By amending** general preference order M-21, WPB announced that cast iron soil pipe and its fittings had been freed from all restrictions formerly imposed by the order. Under the original order, the delivery of iron products is prohibited except on ratings of A-10 or better. The amendment excepts cast iron soil pipe and its fittings from this prohibition. Cast iron soil pipe remains subject to L-79, which controls the distribution of plumbing, cooking and heating equipment.

Why PERMITE PARTS IS A BETTER NAME --

HERE at Permite we think of ourselves as making PARTS —not just "castings."

To Permite customers this means reduced machining, because of the high degree of accuracy to which Permite Aluminum and Magnesium Castings are produced.

It means castings of superior physical and dimensional quality, insured by advanced foundry technique, careful specification adherence and critical supervision and inspection. Standardization of technique and thorough laboratory control, supported by X-ray inspection and spectographic analysis to insure physical qualities, are further factors contributing to the uniformly high quality of the finished parts.

To users of Permite Castings this all means Cast PARTS that are easy to finish and use, with minimum machining and maximum production.

Today

war requirements take most of our production. But when Victory is won, Permite advanced technique in making cast parts of superior quality will be fully available for those better products of a better postwar world.

Sen. George Urges New Reconversion Plan

Washington

• • • **To deal with** all postwar economic problems including contract cancellation, plant reconversion, and disposal of surplus property, the George (Senate) Postwar Committee on Tuesday recommended that legislation be enacted to divorce all agencies of the government, except the Office of War Mobilization, from authority over reconversion through creation of an Office of Demobilization.

The recommendations are seen as an attempt to withdraw from the War and Navy Departments any authority they have asserted over when civilian production should start. Also, it is seen as a direct effort to make all postwar planning the province of Congress and not of the President and his advisers. The report says that in the Office of Demobilization there should be created a fulltime board appointed by the director and composed of the ablest men whose services can be obtained

Russian Sailor: Nina Lickochova, 4th Mate on the Russian icebreaker that docked at Seattle for repairs, was the only woman officer aboard. She's proficient with rifle and some of the large guns.

CHICAGO MOUNTED WHEELS—The first small wheels ever mounted on stationary shanks, they have maintained their supremacy through the years. Over 300 sizes, styles and grains—one to suit every job. They're tough, long lived, dependable.

CHICAGO GRINDING WHEELS—To break production bottlenecks due to the crying need for small wheels, we gave up making all larger sizes for the duration—with full WPB approval—and now specialize on sizes 3" in diameter and under.

America's Unbeatables

Yes, all the wheels in our line are small, but powerful and *swift tools of war* doing their stuff day in and day out — making it possible to speed through everything that requires precision internal or external grinding, polishing and burring — bombsights, planes, tanks, guns, intricate instruments, etc.

PROMPT DELIVERY—Come to America's Headquarters for Small Wheels, custom built to your order. No waiting for shipments now, and after the war a reliable source of supply. Our central location is another asset—cuts shipping time to most plants.

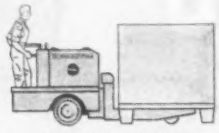
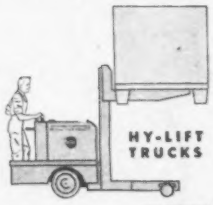
NEW Baker Truck Catalog

GIVES THE ANSWERS TO YOUR MATERIAL HANDLING PROBLEMS

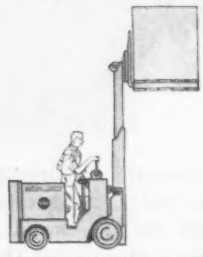
Here's real help for any plant or warehouse faced with transportation problems. The Baker Electric Truck Catalog No. 52 is a handbook of information on material handling, designed to facilitate selection of the proper equipment for any set of requirements. In addition to describing the 47 standard Baker Electric Trucks, it covers many special models designed for unusual handling operations.



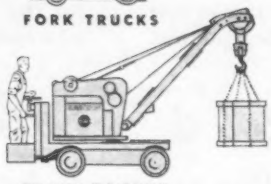
LOW-LIFT TRUCKS



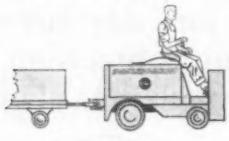
HY-LIFT TRUCKS



FORK TRUCKS



CRANE TRUCKS



TRACTORS

PLATFORM TRUCKS

Many actual case histories show Baker Trucks speeding production, saving time and money and conserving man-power in a wide variety of installations. You are almost sure to find problems comparable to those in your plant, and you can profit from the experience of others in solving them.

• • •

Plant and production managers, traffic managers, superintendents, purchasing agents and any others concerned with material handling will find this book a valuable source of information. Write for your copy today.

BAKER INDUSTRIAL TRUCK DIVISION
of the Baker Raulang Company
2175 WEST 25th STREET • • • CLEVELAND, OHIO
In Canada—Railway and Power Engineering Corporation, Ltd.

Baker INDUSTRIAL TRUCKS

upon whom the director can call constantly for advice and assistance.

The report says that the Office of Demobilization should not be an operating agency but that policies and regulations should be carried out by agencies already established.

"In outlining its duties and powers it should be made plain that upon it rests the responsibility for having formulated complete plans for industrial reconversion to peace and for the coordination of all such plans, and that its power to issue orders to other agencies of the government with reference to industrial reconversion plans and policies is absolute, subject only to control of the Office of War Mobilization until hostilities cease," says the report.

The committee remarked that the economic life of this nation must not be permitted to become dependent upon Washington directives as it has been for war and also that the paramount consideration in the handling of all demobilization problems should be the preservation and strengthening of the American system of free competitive enterprise. All war plants and war surpluses should be handled by the demobilization agency in such a manner to promote such enterprise, said the report.

Nelson Reports Munitions Output in December Steady

• • • In his latest monthly report on munitions production, issued Jan. 25, Donald M. Nelson, chairman of the WPB, said output of munitions in December was at the same level as in November. The maintenance of the November production level was accounted for primarily by the fact that airplanes were up 5 per cent by weight (a total of 8802 planes).

Munitions production for all of 1943 was up more than 80 per cent above the 1942 total.

By major categories, December munitions production showed these percentage changes over November:

Aircraft, up 5 per cent.
Ships (value of construction work done on Navy, Army and Maritime vessels, including repairs and maintenance, down 2 per cent (preliminary estimate).
Guns and fire-control equipment, down 2 per cent.
Ammunition, down 7 per cent.
Combat and motor vehicles, down 1 per cent.
Communication, electronic equipment, up 4 per cent.

For December, the WPB over-all index of munitions production (based on November, 1941, at 100) was up 1 point, to 662 (preliminary).

SELF-LUBRICATING BRONZE BEARINGS at 37 POINTS*...

AND PRECISION, PRELOADED BALL BEARING HEADSTOCK

*Arrows indicate location and number of self-lubricating bearings in Logan Quick Change Gear Lathe. All Logan Lathes are similarly protected.

The day you install a Logan Lathe you end your worries about the constant oiling of vital parts. Take, for example, the Logan Quick Change Gear Lathe shown above. At 37 points where plain, oil-thirsty bearings are ordinarily furnished, this lathe gives you *self-lubricating bronze bearings*. Here is a feature of Logan advanced design which automatically eliminates a prime cause of breakdowns. Furthermore, the spindle on this and all Logan Lathes turns on precision, preloaded ball bearings that never need lubrication. This Logan combination of self-lubricating bronze bearings with precision, preloaded ball bearing spindle mounting forms another important reason why Logan Lathes are setting remarkable records for sustained accuracy . . . high speed, low cost production . . . longer machine life. Write today for the new catalog that gives you complete information on the advanced design features of all models of Logan Lathes.

Here's How — and Why The Spencer Turbo-Compressor

A familiar sight—but do you know how it works and why it is the preference of leading gas and oil-fired equipment manufacturers? Here are a few of the answers:

1. *Constant pressure automatic* with varying loads.
2. *Power* used in proportion to amount of air delivered.
3. High efficiency at all loads.
4. *Quiet*, with no vibration. Long life and no special foundations required.
5. *Simple* as an electric fan, yet built like a bridge.
6. Low peripheral speeds—large ball bearings, wide clearances. They last a lifetime.

The inside story of Spencer Turbo-Compressors is given in our bulletins and the Turbo - Compressor Data - Book, sent on request.

Critical Metals Use Urged in Aircraft

Washington

• • • **Recent favorable** changes in the supply-requirements position of copper, zinc, aluminum, magnesium, ferro-alloys, and alloy steel necessitate re-examination of aircraft conservation policies, according to the Operating Committee on Aircraft Materials Conservation, Aircraft Production Board. These changes resulted from cutbacks in the programs of the services, better control over distribution and use, past conservation measures, and other factors, and will result in wider use of these metals in aircraft construction.

Copper as a metal is in a fairly satisfactory supply condition, and APB recommended that all previous uses for which substitutes to some previously less critical material was made be reviewed with the idea of reverting to copper.

Copper base alloy sheet and strip has been most substantially relieved by cutbacks in the small arms ammunitions program. The presently available strip capacity, however, is not pound for pound in accordance with the reduction in ammunitions requirements. Military requirements for copper base alloy rod are somewhat increased. Capacity, however, exists in brass mills to handle some additional volume.

Copper base alloy tubing capacity exists for sizes under 4-in. except for alloys that are extruded. Brass mill copper products capacity is available with the exception of copper tubing over 4-in. and small size thin wall tubing. Capacity is available for copper wire and cable with the exception of cords and cable involving fine wire and stranding. Casting capacity is available, but there is a limited supply of scrap of the proper grade to produce higher copper content castings of 80 per cent or higher copper. Yellow brass castings are in relatively easy supply.

Supply and requirements of zinc have been in close balance, but recent cutbacks in small arms ammunition will create surpluses. Reconversion to and new uses for zinc for sound military purposes are encouraged. Its use in place of cadmium must be increased.

The improvement in the availability of aluminum obviates the need for further substitution of other materials, and new uses of some aluminum products for military use are encouraged. The use of secondary instead

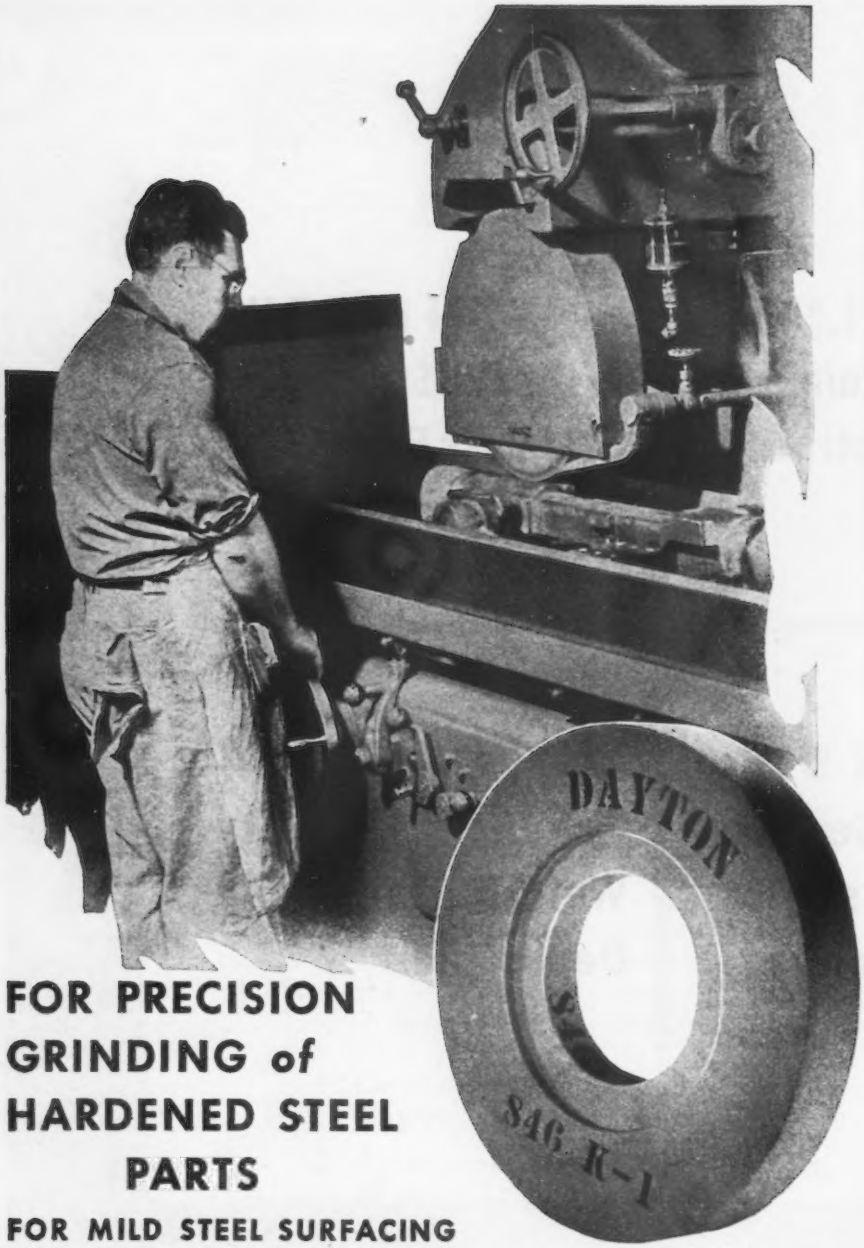
"QUALITY WELD METAL EASILY DEPOSITED"



FOR PRECISION GRINDING of HARDENED STEEL PARTS

FOR MILD STEEL SURFACING

Almost daily this 846-K-1 Dayton wheel makes new friends. Not every wheel can make and support that statement.

Some find the 846-K-1 Dayton particularly effective when surfacing mild steel—maximum removal of stock with little wear on the wheel.

Others find it equally suitable for precision grinding operations—excellent finish—high production.

Still others use it, not to surface some one material only, but to process a variety of materials—high production and long wear the invariable result.

It may be that you are puzzled over some surface grinding problem. It may be that a Dayton 846-K-1 would solve that problem. Why not find out? Outline that problem by letter, wire, or phone. A Dayton 846-K-1, or some other Dayton wheel perhaps, may solve it for you.

Dayton Wheels in all types and sizes for all grinding requirements.

SIMONDS WORDEN WHITE COMPANY, 711 NEGLEY PLACE, DAYTON, OHIO

DAYTON GRINDING WHEELS

of primary aluminum in castings and powders where consistent with required performance must be continued. New uses for permanent mold casting products are discouraged. Consideration for new uses will be given to the following: Aluminum sheet, strip, plate, foil, rod, bar, wire, cable, rolled and extruded tubing and shapes, rivets, and sand and die castings.

New uses of magnesium for forgings are discouraged, but the following forms are currently available: Extruded shapes, rods, bars, and tubing; sheet, strip and plate; and castings, particularly permanent mold and die castings.

All common ferro-alloys are in ample supply. Columbium is very limited. Alloy steel is in ample supply excepting where facilities for sheet, plates, and seamless tubing are involved. Tool steel supply exceeds current demands.

Beryllium-copper supplies are adequate to meet essential aircraft requirements, and it is expected that it will be possible to furnish this material to all consumers who require its use and who are authorized to receive it under WPB and CMP regulations. While aircraft use restrictions may be eased, the material should be procured in forms that will generate the least scrap in processing.

WEAPON INVENTOR? *Dr. Vladimir K. Zworykin, associated with the Radio Corp. of America research department at Camden and Princeton, N. J., is believed to be the "Zworykin" credited by Swedish scientists on Jan. 4 as the inventor of the device that permits RAF bombers to bomb Germany accurately through the clouds.*

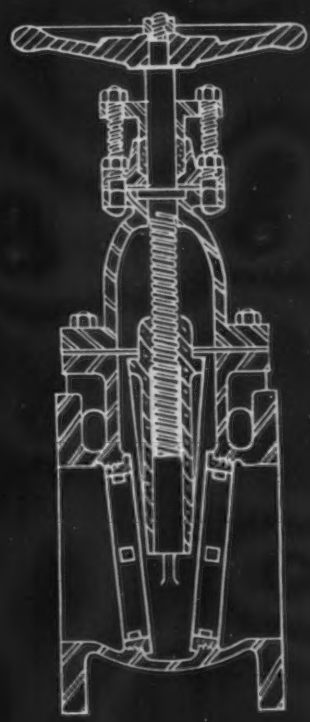
Need any Help *Combating* HEAT AND CORROSION?

Ask RUSTLESS



Temperatures as high as 1000° F, pressures as great as 1500 lbs. per square inch, corrosive conditions capable of quickly destroying most materials — these are the exacting conditions under which Rustless Stainless Steels are used in the vital production of high octane gasoline by the catalytic cracking process.

Gate valves, for example, with Rustless Stainless Steel wedges, seats, stems and other important parts operate under such conditions. Thus, Rustless Stainless Steels are constantly proving their unusual properties and uniform high quality.

Are these conditions unusually severe? Not at all. They are typical of many industries where heat and corrosion are necessary process factors.

If your product must combat heat or corrosion, call on Rustless to furnish technical experience and uniform high quality Stainless Steels. Contact our nearest local office.

When You Want To Know About Stainless

Ask RUSTLESS

Now available for additional wartime applications. STAINLESS STEELS provide means of improving the performance of our fighting equipment.

RUSTLESS will be glad to help you select the proper grade.

Ex-Foundrymen Called

Cleveland

• • • **An urgent call for retired foundry workers too old for physical labor but who can instruct others in foundry work, has been issued by the Cleveland War Manpower Commission office. Older workers experienced as core makers, bench, floor or machine molders, are needed as instructors in a Michigan foundry, while foundries in Ohio, Michigan, and Kentucky are in urgent need of foundry labor. Applicants for instructor jobs or for foundry labor jobs should apply at the nearest U.S.E.S. office.**

Furnace Builders Begin to Catch Up on Order Backlogs

• • • **Makers of heat** treating furnaces are catching up on their backlog, which are now equivalent to about four months' output, according to recent WPB date. Current monthly shipments are only 50 per cent of the peak level of late 1942 and early 1943, the WPB says. New orders, which totaled close to $23,000,000 in early 1942, are reported to be down to four or five million dollars' worth of business per month. The downward trend has ended and stabilization can be expected, says WPB.

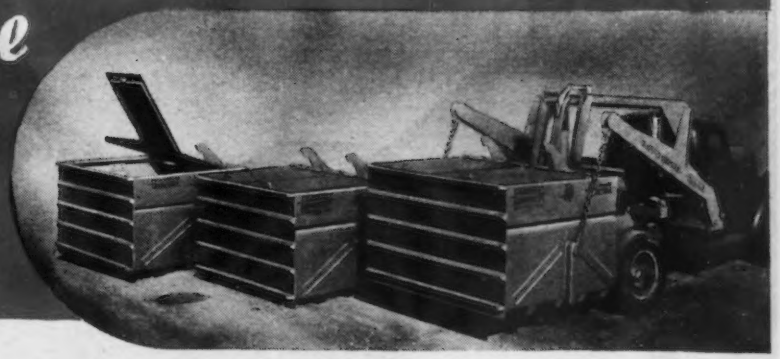
They spot them throughout the plant



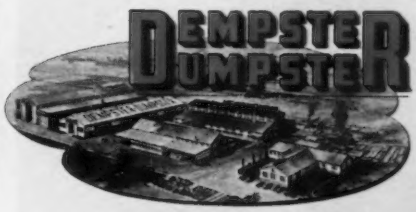
Another Dempster Development For Industrial Materials Handling

★ Another typical example of how the Dempster-Dumpster is saving time, manpower, trucks, tires, and gas in leading industrial plants of almost every classification.

In this case, twenty standard Dempster-Dumpster drop-bottom bodies of 6 cu. yd. capacity each, equipped with special twin, self-balancing, spring hinged tops, are spotted throughout one of America's most vital war factories. A few are placed in convenient spots for receiving waste and rubbish. Others are placed at strategic points for recovering metal shavings. As each body is filled, forked truck conveys loaded body to convenient point where truck, equipped with the Dempster-Dumpster Hoisting unit, hoists load to carrying position, and dumps it at delivery point, all under full control from driver's seat. When empty body is returned, another loaded one, perhaps with a different type of material, is there for hauling and dumping . . . an uninterrupted cycle of materials handling using twenty bodies but with only one truck.

In dozens of other plants, various types of bodies are in use handling materials of almost every description from dust to liquid . . . light to heavy up to 7½ tons pay load . . . finished and unfinished products . . . hot materials up to 1500 degrees F . . . and in every operation with one truck serving from 6 to 50 bodies.

The chances are that the advantages of the Dempster-Dumpster can and should be adapted to your plant. Let our engineers cooperate with you. Write for our complete operating manual No. 242 now.



Illustrations on this page tell the operating story of the Dempster-Dumpster.

Top right shows a loaded body ready for hoisting. Shown also in this photo is the special twin, self-balancing, spring hinged tops on this particular body.

Center Photo shows loaded body in carrying position.

Bottom Photo illustrates instant, or controlled, dumping method of the Dempster-Dumpster bottom-dumping type of body.

Types of bodies available are unlimited. Your requirements determine the design. Cooperation of our engineers with those of the customer has corrected hundreds of materials handling problems and at tremendous savings.

Dempster Brothers, Inc., 824 Springdale, Knoxville 17, Tennessee

Forge and Foundry Problems Studied

• • • **An improvement in** safety and health conditions, as well as increases in unskilled wage brackets, will be necessary before foundry and forge industry production can meet demands, the special foundry and forge shop Labor Advisory Committee has reported to the Office of Labor Production. The committee consists of 14 representatives of AFL and CIO unions in the critical foundry and forge shop industry.

The committee recently discussed with representatives of government agencies health and safety conditions prevailing in foundries and forge shops. The committee requested the Division of Labor Standards to intensify inspection procedures to obtain more thoroughgoing compliance with requirements of the Walsh-Healy Act and the various state safety codes for foundries and forge shops. The Walsh-Healy Act requires concerns undertaking Government work to provide safe working conditions for their employees.

The committee also outlined the manpower difficulties that foundries face, due in part to the inherently unattractive nature of foundry operations. New workers refuse to enter the industry at present wage scales, and therefore WLB should reconsider present area wage brackets established for the foundry industry.

The committee requested that in areas where WLB undertakes to fix wage scales, representatives of the unions be provided with the background data on which WLB proposes to act. This procedure would permit the unions to provide additional data if, in their opinion, information of the WLB seems inadequate. The committee further requested WLB to establish a special panel to hear foundry and forge shop cases. This action was based upon a conviction that only a special panel can adequately understand the unusual problems that prevail in the industry.

The committee announced it had received a report from WMC stating that employment in foundries—where manpower shortages are critical—has risen two per cent. The gain in employment is ascribed to the activities of the 15 Area Foundry and Forge Shop Production Committees, which have been operating throughout the country under joint WPB and WMC sponsorship.

Where **shorter** responses mean **longer** life . . .

W·A·B *controls are serving*

Clearing the way in amphibious landings—breaking trail for battleships, carriers, cruisers, and destroyers—riding herd on convoys and doing anti-submarine work—minesweepers have a job second only to submarines in the hazards encountered. Precise and immediate response to the orders of the bridge may often mean the safety of the vessel, and the success of a mission. W·A·B Controls are now serving on a number of minesweepers.

* * * *

The marine field is only one of many where W·A·B Controls are helping or can help to solve difficult control problems. The job the controls are doing here gives an excellent picture of their possibilities, and may suggest places where they can serve for *you*.

W·A·B Control Systems for ships concentrate command of all engine maneuvering in small, compact stations, located on the bridge . . . in the engine room . . . or both. The entire cycle of engine maneuvering . . . speed control, clutching, braking and reversing . . . is governed by the movement of a small handle. Load balancing and synchronization of multiple-engine drives is simplified, simple interlocks prevent damage to equipment through operating errors.

If your post-war planning for your plant or your product requires a safe, simple, completely dependable control, it will pay you to investigate W·A·B Controls.

GUSHER
COOLANT PUMPS

Gusher Coolant Pumps are used by leading machine tool manufacturers. They are simple in design. They have few moving parts. They require minimum maintenance. Not injured by chips or grit. Capacity is from trickle to 200 g.p.m. Many exclusive advantages. There's a type and size to meet your requirements. Write for new complete catalogue.

●

Model 1-P3
"V"-Belt

The essential features are the same as motor-driven Gusher models, the only difference being the substitution of an automatically oiled gear-driven mechanism for the motor.

THE RUTHMAN MACHINERY CO.

1821 READING ROAD CINCINNATI 2, OHIO

LARGEST EXCLUSIVE BUILDERS OF COOLANT PUMPS

Briefly Told—

• Helping reduce the weight of Flying Fortresses, a new type of engine mount which requires less rubber was announced by the Goodyear Tire & Rubber Co. Another major advantage in the new type mount is the fact that it reduces vibration. The mounts permit the engines to reach their vibration peak much earlier than other types. Often the engines can reach their vibration peaks with the new engine mounts before flying operation ranges are reached. This permits more accurate aiming of bombs and guns, longer life for engines, and less nerve-strain on pilots and crew members. The new engine mounts decrease the weight of each Flying Fortress by about 15 lb.

●

• Conductive rubber gun heating pads are installed on aircraft machine guns and aerial cannon. These pads keep the plane's armament at proper firing temperatures at all times, and make possible pre-heating of gun breeches while the plane is grounded or maintaining required temperatures for instantaneous use at high altitudes. This heater, developed by U. S. Rubber Co., prevents the jamming of guns due to high viscosity of oils and greases and the contracting of steel under certain atmospheric conditions.

●

• U. S. Rubber Co., through an investment in capital stock, has become associated with Compania Croydon del Pacifico, S. A., leading rubber manufacturer of Colombia, S. A. The Colombian company, located at Cali, Colombia, uses the Pacific Coast seaport of Benaventura, and will continue to manufacture its own line of products under its own name. In addition the Croydon company will eventually produce and distribute in Colombia certain U. S. Rubber lines. Present products of the company include canvas rubber soled shoes, molded rubber products, a line of industrial rubber goods and camelback for tire retreading.

●

• Surpassing pre-ration figures 426 tons of tin cans were collected by the Buffalo War Council's salvage division Jan. 23d. The lot was sent to Vulcan Detinning Co., Pittsburgh.

●

• Entry of the screw machine industry into the field of plastics after the war and greater expansion in that period were forecast by Orrin B. Werntz, executive secretary of the National Screw Machine Products Association. At the annual meeting of the association he said that plastics can be machined in bar form on screw machines and the industry would widen its activities after the war to include such lines of products.

●

• During 1943, American Locomotive Co. built more diesel railroad locomotives than any other company in the world. Included were large numbers of switch engines for American railroads, locomotives for military use overseas, and giant freight engines to

WEAR-TESTED MATERIALS STEP UP TODAY'S PRODUCTION

American war industries quickly found they could obtain new speed from the consistent accuracy of Woodworth precision gages, ground thread taps, form tools and other perishable production tools.

Wear-tested metals give Woodworth accuracy its extra-long life. Every piece of metal used in Woodworth gages is tested for wear by the severest modern methods.

Old in experience and resourcefulness, Woodworth has charted new ways to speed war production and to cut inspection costs.

After the war, we shall continue to build to that same accuracy, passing on to Woodworth customers all the benefits of Woodworth production methods and their resultant efficiency, which the new peacetime economy will demand.

Our Engineering and Development Departments are available for consultation on special operating and production problems involving gaging and production tools.

DUMB DORA MAY BURN DOWN YOUR PLANT!

Unless you protect oily floors with *SPEEDI-DRI*

There's one (or more) in every Plant. Rules or no rules, some Dumb Doras *will* sneak smokes and drop matches or butts on oil-soaked waste, rags and other inflammable absorbents. You can foil these "unconscious saboteurs" by spreading SPEEDI-DRI, the famous oil- and grease-absorbent on *all* oily floors. It works fast. It's economical. It retards fire, even when oil soaked (just ask your insurance company about that!). What's more, it sets up an immediate non-skid surface preventing many a falling and slipping accident —a major cause of industrial casualties. SPEEDI-DRI will brighten your plant, improve morale, speed production, and save vital manpower by freeing porter labor for more important jobs. Write for literature and FREE SAMPLE.

●

• The Surplus Program Section of the WP
Redistribution Division, in cooperation wi
the Metals Reserve Co., published a catalog
of 30,690 new surplus steel valves of vario
sizes and types for the use of war contracto
or others. It indicates the types of valve
catalogue specifications, manufacturers' name
and state location. The list includes bo
multi-purpose and specific use valves. Re
gional WPB offices and claimant agencie
will have copies of the list.

●

• It has been widely assumed that 100 octan
gasoline developed in large quantities for wa
planes will be the super fuel of postwar auto
mobiles. Actually, the octane number of gas
line generally available for automobiles afte
the war is not likely to average more than
three numbers higher than the prewar prod
uct. This is primarily because the economic
of producing aviation gasoline for war and
motor gasolines for peace-time operation ar
vastly different. Competition makes it neces
sary to employ techniques that will produce
as much gasoline of as good a quality as auto
mobile engines can use, and no better, from
the least amount of crude and at as low a cost
as possible. Many of the practices employed
to produce 100 octane are not economical
enough for producing motor gasoline.

●

• The Chicago, Milwaukee, St. Paul & Pacific
Railroad plans to build and improve equip
ment for which it has asked the interstate
commerce commission to approve a $7,260,000
trust issue. In addition to erecting some 150
freight cars and gondolas, the road will buy
10 steam locomotives and six large diesels.

●

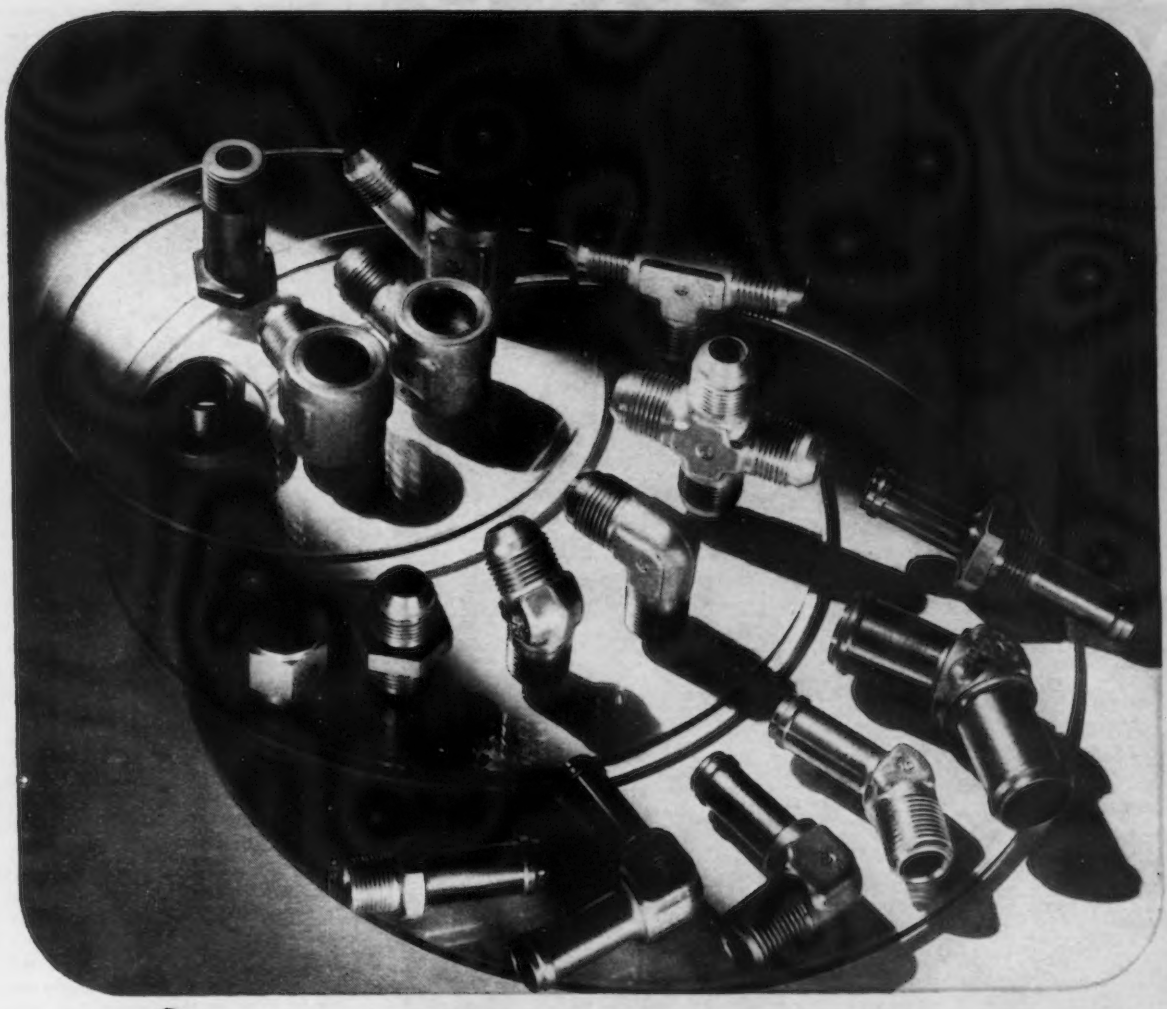
• Pan American Airways has opened an
all-freight service from Miami to certain
Caribbean points. Two principal routes
are being operated—between Miami and
San Juan, Puerto Rico, and between
Miami and Barranquilla, Colombia. An-
tilla, on the north coast of Cuba, and
Port-au-Prince, Haiti, will be served on
the 1200-mile route between Miami and
San Juan. Kingston, Jamaica, will be a
stop on the 1100-mile trans-Caribbean
route to Barranquilla. These points will
be served by a four-engine flying freighter
which will carry 8800 lb. of cargo at a
cruising speed of 150 miles per hour.

●

• Invasion boats of synthetic rubber are
being produced in quantity at the Wood-
socket plant of United States Rubber Co.
These inflatable boats are equipped with
quick release towing bridles so they can
be towed behind fast boats and released
to beach themselves by their own momen-
tum. Each will carry 10 men with full
invasion equipment. Equipment includes
12 paddles, outboard motors, repair kits,
a signal flag, bullet hole plugs, an extra
inflatable floor for added buoyancy and a
life line all around the boat.

●

• *A WPB 50-page catalogue of 30,690 new surplus steel valves of various sizes and types has been published. It indicates the type of valves, catalogue specifications, manufacturers'*



Ammunition for today and tomorrow

"Fittings" the trade calls them. But the term tells only half the story—and the least exciting half, at that. For these carefully-made but inconsequential-looking gimmicks are vital to every mobile fighting unit whether it wages battle on land . . . on sea . . . or in the sky. They are, in fact—ammunition!

These assorted fittings have been produced by the millions-per-week for war purposes in the four plants of The Weatherhead Company. And with Victory and Peace, they will become the ammunition with which we shall be prepared to help you build the better world for which we are all fighting.

Look Ahead with (W)

HOLYOKE, MASS., U.S.A.

names, and state location. It will be available for inspection by steel valve users in WPB's Regional or District Offices. Claimant Agencies will also have copies of the catalogue available. Persons needing steel valves may learn their location through the Surplus Program Section of WPB, 155 East 44th Street, New York City.

●

• A new all-cargo air service, Aerovias Venezolanes, S. A. (Avensa), to operate within Venezuela, has been organized. It will serve interior points. Technical guidance for the line will be contributed by Pan American World Airways. Pan American will have a minority stock interest. The line will carry cargo on a charter basis as far south as Santa Elena, near the diamond fields. The company will operate Ford tri-motor planes, a type which has been used in cargo and passenger operations in Cuba, Colombia and Central America.

●

• Police departments of three Cleveland plants of Republic Steel Corp. received Auxiliary Military Police Guidon Awards from the War Department. The presentation was the first in the Cleveland district, Continuous Security of the Fifth Service Command which covers northern Ohio and Indiana. The citation states: "This award is a tribute to their patriotism and efforts extended in providing internal and external protection of their plants against sabotage, espionage and natural hazards, and to supplement the Army in wartime emergency situations." The award was made by Major George J. Hales, district chief, to Capt. Raymond Meredith of the Cleveland District, Capt. William G. Holt of the Bolt & Nut Division, and Capt. Emmett M. Crum of the Cleveland plant of Truscon Steel Co.

●

• The Massey-Harris Co., Racine, Wis., has a new contract for rebuilding gun carriages which will be done in the former Nash plant, taken over about two years ago when the firm received its contract for building M-5 tanks. The company also is carrying on an increased farm machinery program.

●

• Master Metal Products, Inc., Buffalo, has completed its government orders for bomb kits, tool chests and refuse cans for the armed forces. According to president Edward J. Tate, the plant made more than 500,000 bomb kits for the Navy, 4000 step-on refuse cans for the Medical Corps, and tool chests for Army tanks and government arsenals. Production now is confined to tool chests for war industries and the firm is awaiting a signal to resume producing civilian refuse cans.

●

• Longer lives for propeller shafts on minesweepers, tugs, and similar seacraft are possible as the result of a new adaptation for synthetic rubber announced by Goodyear Tire & Rubber Co. Protecting the propeller shafts from corrosive action of sea water, the synthetic rubber propeller shaft coverings can increase the life of shafts by as much as 1000 per cent, according to Goodyear. The synthetic rubber is applied to a propeller shaft in a sheet about 3/16-in. thick after the shaft has been shot-blasted and has received a preliminary coat of cement. Then the shaft and its rubber covering, are cured under intense heat to insure firm adhesion of the coating to the metal.

THERMONIC

THE MOST EFFICIENT AND ECONOMICAL SYSTEM FOR INDUCTION HEATING

HITLER & CO.

SHIVER

WHEN

THIS "ORGAN"

PLAYS

The "organ" reproduced to the right, and so vividly dramatized by Noblitt-Sparks, is a Thermonic production set-up. It "plays off" an "octave" of highly specialized brazes every 65 seconds . . . 440 per hr!

The tall, pipe-like parts shown at the right are burster wells (aerial bomb exploders) in the stage of going through an important brazing step, while the large central illustration visualizes the actual operation involved. The requirement here called for brazing a small screw machine part onto the end of a steel tube . . . the condition being that the inside threading of the pieces be kept free from the flow of the brazing alloy!

That this brazing operation was successfully and speedily accomplished by Thermonic is in no uncertain terms indicated by the Noblitt-Sparks copy headline! It packs a knock-out punch!

The versatility of Thermonic Induction Heating equipment is doing much to speed up vital war requirements. . . . It's boosting production by reducing, from minutes to seconds, operations calling for Brazing, Hardening, Forging, Melting and Annealing. . . . It cuts power and maintenance costs to fractions. . . . And unskilled labor quickly becomes expert in handling its many functions. For complete information about our equipment's proven advantages, we invite your inquiries. The counsel of Thermonic's engineering staff is at your service.

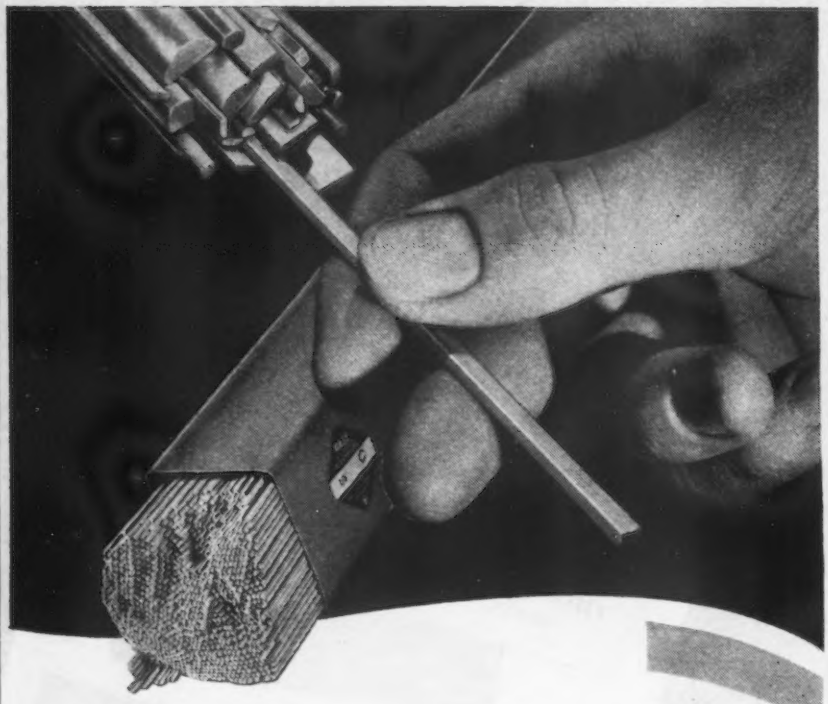
PAGE for WIRE



With mills practically at capacity producing wire for war and for essential industry, users of wire find that there are many things that they can do to conserve essential materials.

SHAPED WIRE: Use standard shapes. That can be done easily. **PAGE** has a wide variety, including ovals, hexagon, octagon, square, channel, keystone, flat, half-round, etc.—in diameters to ⅜"—with end section areas to .250 square inch.

WELDING ELECTRODES: Be certain that electrodes are correct in analysis for the job. Lean toward larger sizes for economy. See that no excess metal is deposited in the weld and that your men use electrodes right down to the holder.

GENERAL WIRE: The situation in such products as Spring Wire, Bond Wire, Telephone Wire, etc., is not subject to early improvement. It continues to be important to check waste.

If **PAGE** experience can help you work out any of these details, we will be glad to cooperate.

New Loan Policy for Small Firms Set

• • • **A new loan policy** effective Feb. 1, was announced by Maury Maverick, chairman of the Smaller War Plants Corp. It increases the amount that banks are permitted to carry under a deferred participation from $100,000 to $250,000 where the bank takes a direct participation in the loan of 10 per cent or more.

Interest up to 6 per cent per annum is allowed on that part of the loan which the bank carries at its own risk and on the balance, which is carried under a deferred participation, interest of 4 per cent is charged with the bank paying to SWPC a graduated fee of from one-half of 1 per cent to 1 per cent per annum, depending on the percentage of the bank's participation.

Steel Construction Bookings In 1943 Total 563,584 Tons

New York

• • • **Because the present** volume of fabricated structural steel for construction purposes is so small and conditions are so unusual, the American Institute of Steel Construction discontinued estimating total bookings and shipments and now records only a summarization of reports by the participating members from month to month. These companies represent some 79.8 per cent of the total average bookings of the industry during the years 1923 to 1925.

	Reported to the Institute, Net Tons, 1943	Estimated for Entire Industry, Net Tons, 1942
BOOKINGS

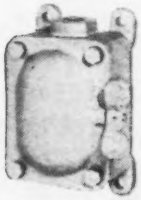
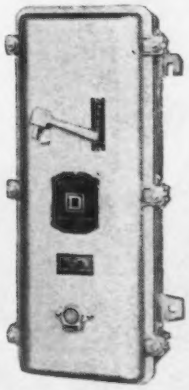
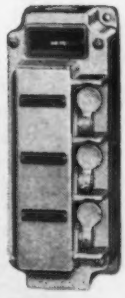
Class 2510 manual starter for motors up to 5 H. P. at 220 volts or 7½ H. P. at 440 volts.



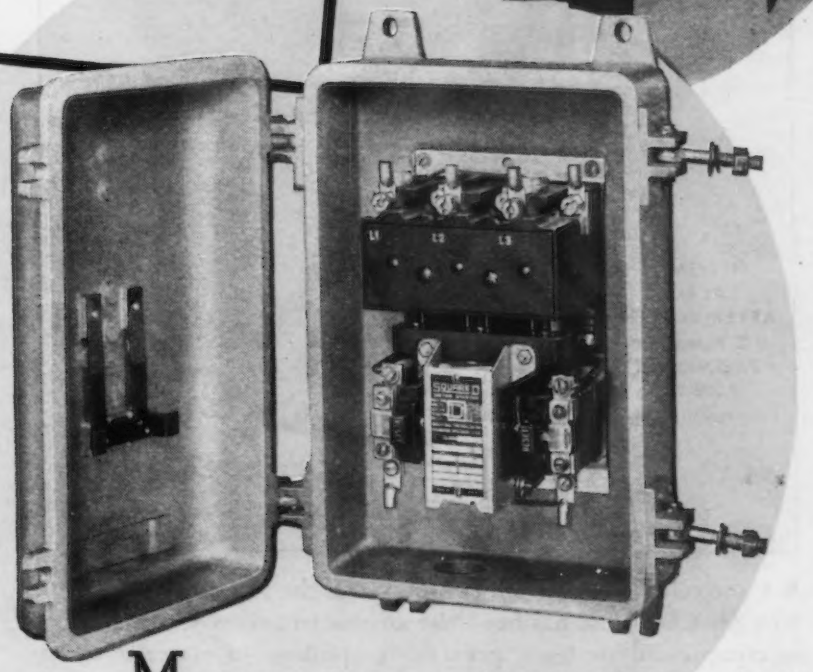
Class 9001, Type BR11 standard duty "Start-Stop" pushbutton station.



Class 8538 combination starter with circuit breaker and magnetic starter in one enclosure.



Class 9001, Type GD-31 three unit heavy duty pushbutton station.



MAGNESIUM dust is readily ignited by an electric spark or arc. Safe operation demands motor control with special dust-excluding enclosures in all locations where it is present.

Square D offers a complete line of control suitable for use in the presence of magnesium, aluminum, or other combustible metal dust. Devices listed for Class II, Group G hazardous grain dust locations, also meet Class II, Group E metal dust requirements.

Manual and magnetic starters, combination starters, reversing starters, push buttons and other accessories are available in a complete range of sizes.

A Square D Field Engineer will be glad to help you select equipment with exactly the right special purpose enclosure for practically any application—from Square D's standard catalog.

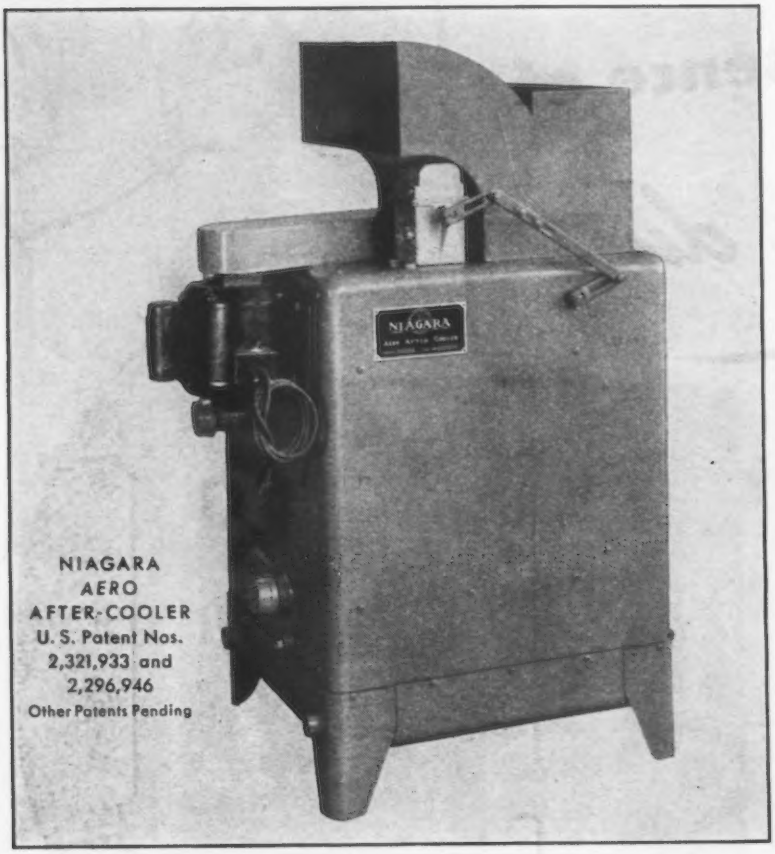
Keeping Water and Oil Out of COMPRESSED AIR



NIAGARA
AERO
AFTER-COOLER
U. S. Patent Nos.
2,321,933 and
2,296,946
Other Patents Pending

● Controlled temperature cooling with the NIAGARA *AERO* AFTER-COOLER has been the answer to excess water and oil in compressed air lines, preventing spoilage of material when compressed air is used in process and preventing damage to pneumatic tools. No refrigeration is required.

The NIAGARA *AERO* AFTER-COOLER both condenses the moisture before it gets into the lines and also provides jacket water of the proper temperature to prevent condensation in the compressor, washing out the lubricating oil.

It helps produce compressed air containing only ½ to ¾ as much moisture as air cooled by conventional equipment. At the same time it saves 95% of the cost of cooling water, pays for itself in a short time. Write for complete information.

Porcelain Enamel Group Maps Postwar Technical Advances

Washington

• • • **Di-electric heating** and induction heating for drying and fusing porcelain enamels are two suggested changes in porcelain enamel processing. These methods of heating may have revolutionary effects upon the application of porcelain finishes. Although such work has not been done previously, the importance in other fields indicate that such methods may be possible. The use of multiple or repeat tanks in cleaning operations and electrolytic cleaning has been suggested.

Atmospheric control of furnaces is progressing with great rapidity, especially when the protective nature of the porcelain enamel coating is important. Electrolytic precipitation of porcelain enamels in spraying, according to many engineers, will result in large reduction in materials used. It will also make application much more complete and uniform, and tend to reduce the loss resulting from irregular or thick coatings.

The importance of research work in

HOOVER

BALL AND BEARING COMPANY, ANN ARBOR, MICHIGAN

A GAY BLADE *that leads a* DOUBLE LIFE

IT WORKS THIS WAY:

Place in machine in usual way, first edge (A) down. As blade submerges in slot, edge (B), set narrower than edge A, clears work freely, undamaged. When A is dulled, invert blade. Edge B then cuts as fast and free as first edge.

Sounds fantastic, doesn't it? But Blu-Mol "Double-Life," a Millers Falls exclusive, is a *high speed* machine blade that actually leads a double life. When one edge is worn out from long toil, just turn it over and go right on sawing. The special set differential eliminates drag and wear on the trailing edge. One Blu-Mol "Double-Life" blade costs 33⅓% less than two molybdenum high speed blades and 47½% less than two tungsten high speed blades. The saving is worth-while.

"Double-Life" blades, while more efficient and economical, are also aiding the drive toward Victory by saving in alloy steel consumption, shipping, storing and handling. Put in your requisition now.

MILLERS FALLS TOOLS SINCE 1868

MILLERS FALLS COMPANY
GREENFIELD, MASSACHUSETTS

the porcelain enamel industry has led the Porcelain Enamel Institute to establish a committee on process development to study new manufacturing methods and report on their adaptability to this industry. This committee consists of: Chairman, L. E. Nordholt, vice-president, Tennessee Enamel Mfg. Co., Nashville, Tenn.; H. D. Carter, research engineer, The Harshaw Chemical Co., Cleveland; R. M. King, associate professor, Department of Ceramic Engineering, Ohio State University, Columbus, Ohio; Edward Mackasek, development engineer, Porcelain Enamel Institute, Washington, D. C.; A. I. Andrews, head of the department of Ceramic Engineering, University of Illinois, Urbana, Ill.; J. W. Hoehl, vice-president, Wolverine Porcelain Enameling Co., Detroit; G. W. Dykstra, engineer, Great Lakes Steel Corp., Detroit; R. E. Tayor, general superintendent, The Enamel Products Co., Cleveland; F. R. Porter, engineer, Inland Steel Co., Indiana Harbor, Ind.

The first meeting of this committee, held on Jan. 18, at Cincinnati, laid out a specific program of inquiry and assigned one new process to each member for further study.

Labor Group Proposes Study Of Machine Tool Conversion

Washington

• • • **The Machine Tools** Labor Advisory Committee in a report to WPB recommended advance planning designed to insure smooth adjustment of the machine tool industry to the changing needs of war production. Committee members expressed particular interest in carrying out a study of problems relating to the disposition of surplus machine tools, conversion to other war work by the machine tool industry and advance planning for eventual conversion to civilian production.

The advisory committee recommended that a preliminary study be undertaken by the Office of Labor Production and the Office of Manpower Requirements before specific recommendations are submitted to WPB. The government presiding officer of the Machine Tools Labor Advisory Committee is David Lasser, assistant director, Plant Productivity Division of the Office of Labor Production.

The advisory committee consists of representatives of important labor unions in the machine tool industry.

Wickman PROFILE GRINDER

TYPICAL EXAMPLES OF WORK GROUND AND INSPECTED ON THIS MACHINE WITHOUT USE OF RADIUS DRESSER OR FORMED WHEEL

Cemented-Carbide Tipped Form Tool
Width of Carbide Tip . . . . . 1¾"
Stock Removed . . . . . approx. .040"
Grinding time including set-up and complete inspection of contour before removal from machine . . . . . 3½ hrs.

Circular Form Tool with Preformed Cemented-Carbide Tips
Stock Removed . . . . . .015"
Grinding time including set-up and complete inspection before removal from machine approx. 2 hrs.

The Wickman Profile Grinder is a machine which makes possible substantial savings in machining time. It produces extremely accurate work, tolerances even closer than ± .0005" being secured with reasonable care in operation.

Of most importance, these production advantages can be effected in your plant with relatively unskilled operators assigned to the machines. Any person of average intelligence can be trained in a very short time to become thoroughly efficient in the Wickman method of profile grinding.

The layout and brain-work are done in the drafting room. The operator has nothing to measure. She sees it done. She knows at all times where every point on the contour is, during its development, in relation to every other point on the tool without removing it from the machine for partial inspection. Write for completely descriptive literature.

Metal Receptacles Shown in Fifteenth Enemy Patent List

• • • **In the fifteenth list of seized** enemy patents available on the obtainment of license from the Alien Property Custodian, various types of metallic receptacles and closures are described. These patents deal with such items as higher pressure vessels, drums, storage tanks and other similar products. Rules and procedures for obtaining licenses to and the manner through which complete patent descriptions may be obtained are shown in the Nov. 4 issue of THE IRON AGE, page 95.

In the items shown in this list, the class number appears at the head of the list, and each separate item shows the sub-class number, patent number, patent description, inventor and his nationality, and the date on which the patent was issued.

Class 220—Metallic receptacles

(1) 2,156,400. Spherical container for storing fluids such as gas and liquids. W. Peckstein, Germany. 5-2-39.

(3) 1,645,944. Shell-shaped body suitable for the allowance of high-pressure stresses. H. Debor, Germany. 10-18-27.

(3) 1,753,871. High-pressure gas-developing cartridge or bottle for portable fire extinguishers as well as for the preparation of sparkling beverages in bottles. G. Schworetzky, Germany. 4-8-30.

(3) 2,029,606. High-pressure joint for pressure vessels. K. Bredtschneider, Germany. 2-4-36.

(3) 2,253,093. High-pressure vessel. L. Raichle and K. Riedinger, Germany. 8-19-41.

(3) 2,312,420. High-pressure container. E. Kopf and R. Wasmuht, Germany. 3-2-43.

(9) 2,043,183. Double-walled vessel for transport and storage of beverages more particularly beer, in which the inner vessel for holding the beverage is removable. K. Mauser, Germany. 6-2-36.

(10) 1,800,082. Jacketed metal drum. J. Knigge, Germany. 4-7-31.

(10) 1,888,899. Metal drum manufactured from stainless steel and intended for liquids which easily acquire a bad taste. P. Wolf, Germany. 11-22-32.

(10) 1,904,755. Jacketed metal drum. P. Wolf, Germany. 4-18-33.

(15) 1,956,512. Metal cask having double walls, more particularly casks of this kind for the transport of beer and similar liquids, the taste of which is very subject to contamination. A. Muller, Germany. 4-24-34.

(20) 1,644,821. Container of the type in which are provided two chambers or compartments each adapted to contain an ingredient or ingredients of a product, thus enclosing the whole of such product while keeping the ingredients separated until ready for use. J. Eckhart, Germany. 10-11-27.

(22) 1,669,333. Partition means for fluid containers, particularly for dyeing machines and the like. W. Gerber, Germany. 5-8-28.

(22) 1,758,335. Device for subdividing liquid containers. J. Schlumpf, Germany. 5-13-30.

(23) 1,731,847. Bronze and tincture container with an intermediate partition, separating the bronze and tincture from one another which can be displaced by pushing or is removable. C. Eckart, Jr., Germany. 10-15-29.

(24) 1,665,827. Packing device for pressure vessels. R. Tillmann, Germany. 4-10-28.

(24.50) 2,101,030. Expansion-plug for barrels and other tanks, fire-tube and water-tube boilers. W. Kunze, Germany. 12-7-37.

(25) 1,656,559. Means for closing manholes in the high-pressure drums of steam boilers working at very high pressures, say 30 to 100 atmospheres and more. O. Hartmann, Germany. 1-17-28.

(26) 1,693,468. Sealing piston for reservoirs for the storage of gas, steam, or easily-evaporating liquids. F. Schurmann, Germany. 11-27-28.

(26) 1,722,863. Sealing piston for reservoirs

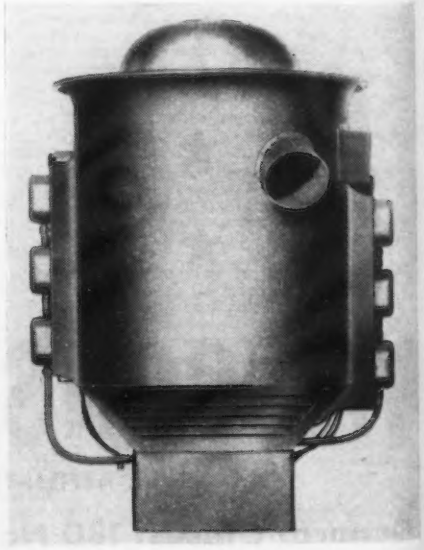
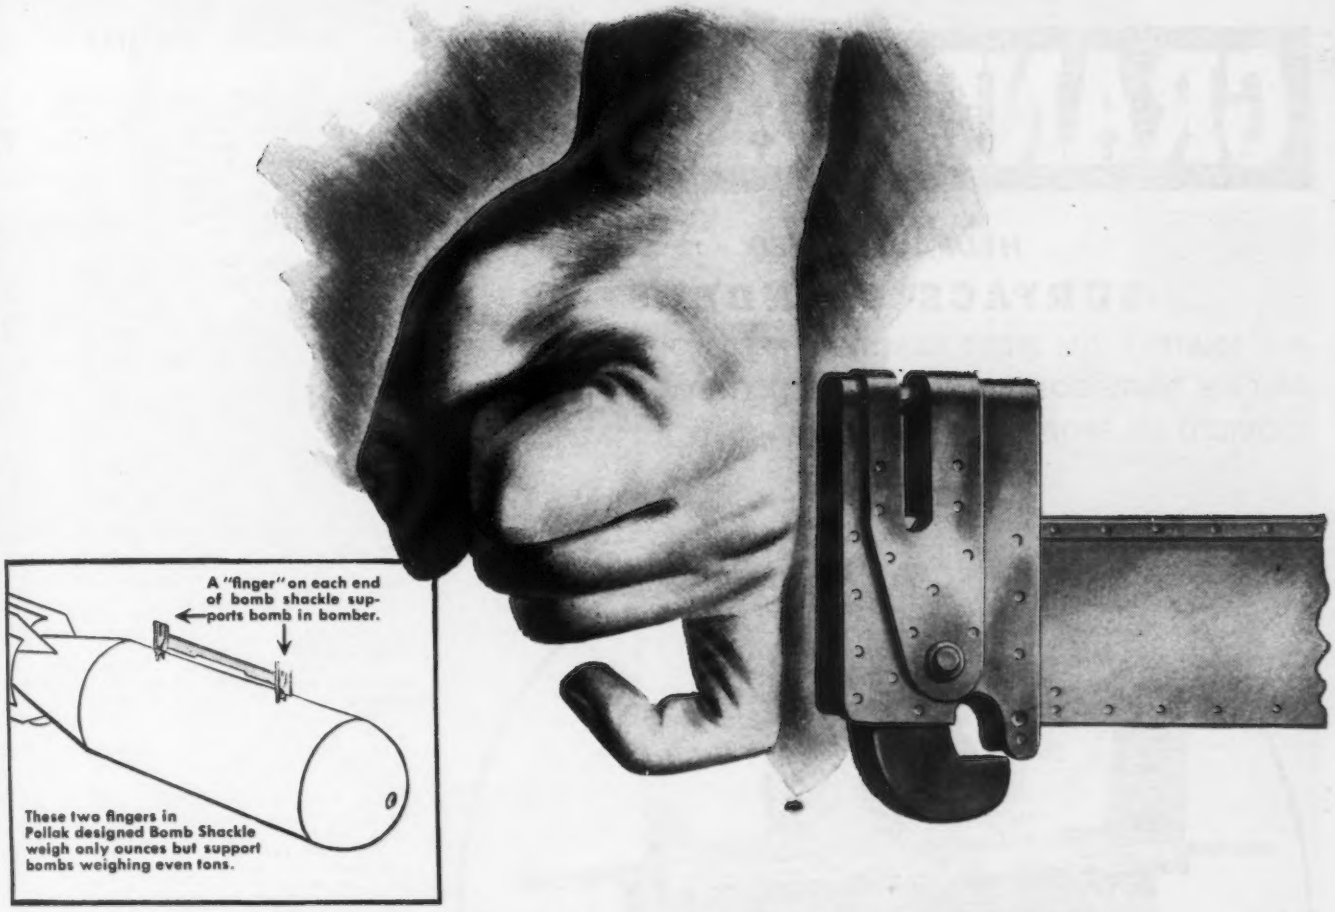
HELICOPTER ENGINE: *This 6-cylinder, opposed, aircooled Franklin engine, built by Aircooled Motors Corp., Syracuse, N. Y., is in service in several experimental helicopter ships. The engine operates in vertical position directly below main rotor shaft.*





EVER SEE THE LITTLE FINGER THAT HOLDS A BOMB?

THERE ARE TWO OF THEM. One on each end of the bomb shackle that supports the bomb in the bomber. These fingers, weighing only a few ounces, carry the weight of bombs weighing many hundreds of pounds. In split second timing with the bomb sight, in all kinds of weather and temperatures, they must release the bomb automatically—precisely—instantly.

Pollak was given contracts by the Army and the Navy to manufacture these all-important bomb shackles, bomb racks, smoke screen generators, fuzes and other precision devices. In record time we organized a large, modern equipped plant to produce and deliver this war materiel. How well we are doing this job is indicated by the Navy having awarded the Pollak Manufacturing Company the Army-Navy "E" and four stars.

This award indicates Pollak's ability and capacity to produce precision products in large quantities and deliver them on time.

Some day, when peace is won and our own war work is finished, this proven ability of Pollak to engineer, develop and manufacture products that are designed and made right—produced in volume and delivered on time—may be of great value to your business.

Now, while you are planning for peacetime products, we suggest that you plan with us. We will be glad to meet with you at your convenience.

POLLAK PRECISION PRODUCTS

Five Army-Navy "E" awards—the Flag and Four Stars—each of which symbolizes six months of Exacting Service to our Armed Forces, have been awarded to Pollak.

Home *is where they park their* Huts!

Official Signal Corps Photo

Ed Miller often cussed the cold of winter in his native state and dreamed of living some day in a warmer climate. But that was before the war. Now Ed's Private Miller, "wintering" with the U. S. Army at a frigid outpost in the far, far North. And home is where he parks his hut!

There are countless Ed Millers somewhere "up there" tonight—and not doing so badly, thank you. For those portable barracks Uncle Sam provides for his men in arms are comfortable beyond belief—well heated, well ventilated and well lighted.

Many, many more of these prefabricated steel dwellings may be needed as our offensive spreads to new lands in this vast global war. So, at the Cincinnati Sheet Metal and Roofing Company (one of several producers of corrugated steel panels for such barracks) every effort is aimed at speeding up production. An example of this was the company's installation of a DeVilbiss automatic spray system which saves time in preparing the steel panels for duty at the front. It applies *over 120 gallons* of olive-drab, lusterless enamel per hour!

Today, DeVilbiss Spray Systems are busy everywhere, coating, painting and finishing things quicker that they may join the fight sooner. *Tomorrow,* when *your* plant is freed for the competitive manufacture of the better peacetime products the whole world expects, DeVilbiss Spray Equipment will help you produce them faster—and at lower cost.

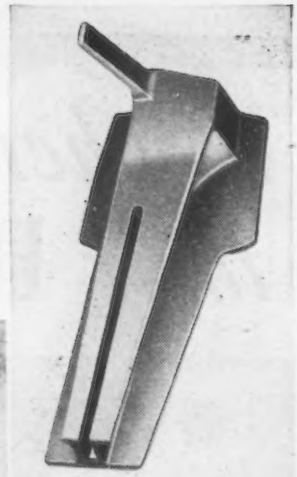
Precision made by FENN for Brewster



OFFICIAL U. S. NAVY PHOTOGRAPH

IN the legendary Corsair, built by Brewster for the Navy, only the finest materials and workmanship find a place. Among these is the bulkhead fitting shown above — a solid aluminum forging, machined to closest tolerances. When F3A Corsair goes into action, everything that engineering skill can contribute has been done to meet the exacting government specifications. From the Fenn Plants a steady flow of precision built parts and assemblies go to manufacturers of planes and other vital war products.

FENN FOR SPECIAL MACHINERY

Years of experience in the design and building of Special Machinery has given the Fenn organization a skill and know-how that may prove helpful to you in the days which lie ahead. We have the plants and facilities for handling almost any size and kind of special machinery job and we welcome inquiries from those who are looking for a dependable source.

PLANNING NOW FOR 1945 PRODUCTION

When the time comes for reconversion to peace time production, Fenn engineers, toolmakers and machinists will be ready to serve you. It is not too early to think of planning now.

Stronger, More Accurate Parts

Produced at Low Cost on...

AJAX *High Speed* Forging Presses

Forgings of aluminum, brass, magnesium and steel for aircraft parts, shell parts, valves and many types of hydraulic fittings can be produced at high production speeds on AJAX Forging Presses. Production by this forging process shapes the grain flow so that the finished forging has a denser, stronger structure for maximum reliability.

The air clutch on the main shaft provides instantaneous application of tremendous pressure in response to the treadle. This not only makes possible higher operating speeds but results in better filled die impressions without excessive flash. Even small parts of intricate design can be forged to close tolerances, economically on AJAX FORGING PRESSES.

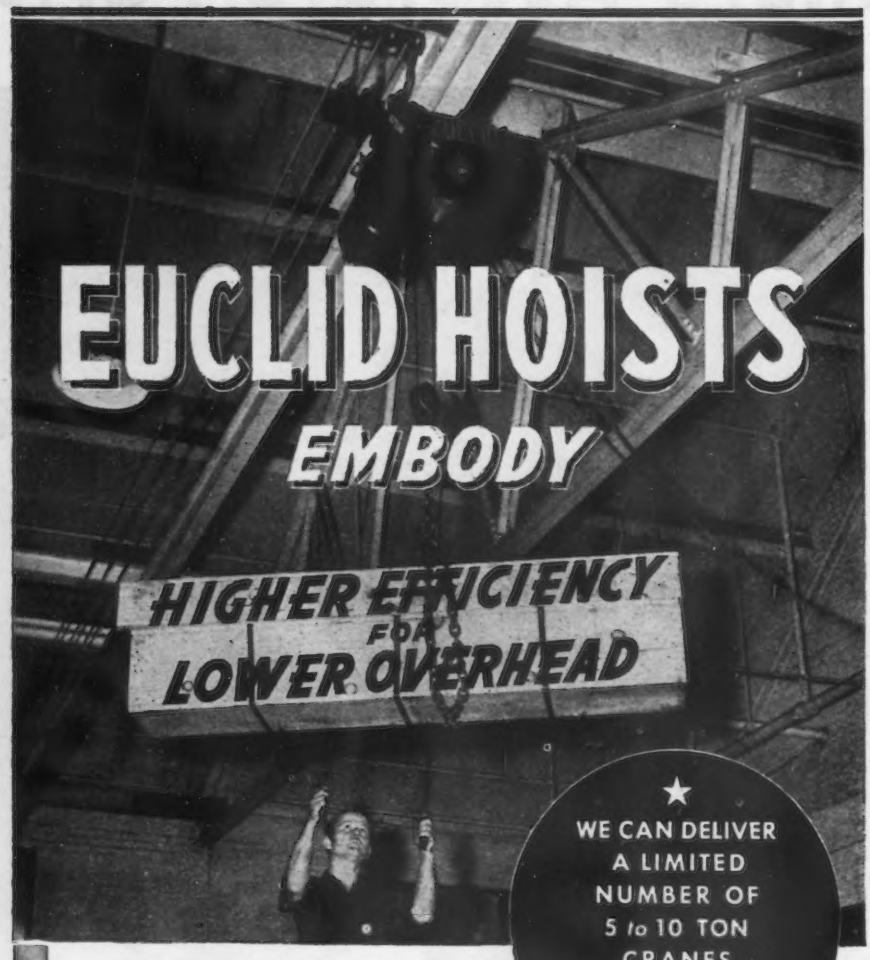
THE AJAX MANUFACTURING COMPANY
EUCLID BRANCH P. O. CLEVELAND, OHIO
621 MARQUETTE BUILDING • CHICAGO, ILLINOIS



The name "Euclid" on a crane or hoist identifies equipment with a consistent reputation for delivering more than the expected quota of work—*more efficiently—at lower overhead!*

The main frame of EUCLID HOISTS is made of rolled steel plates arc welded into a unit that is not only lighter but many times stronger than a cast frame. Alloy steels, heat-treating, anti-friction bearings and double brakes assure a prolonged life of usefulness.

Motors and controllers are the fully enclosed type and wiring is all enclosed in conduit.

Other exclusive EUCLID features assure continuous dependable performance and low maintenance cost.

Brazilian Plant Rolls 45-lb. Rails for New Railroad

• • • **According to Brazilian** reports, 45-lb. rails are now being produced in Brazil for Brazilian railways. The rails are made at the plant of the Compania Siderurgica Belgo-Mineira, at Monlevade. This is one of the older steel plants in Brazil and is not connected with the new National Steel Co. of Brazil. The new plant at Volta Redonda, now under construction, will be the source of heavier rails in excess of 65-lb.

Production of light rails at Monlevada was encouraged as a means of obtaining rails for the 310 mile railroad line being built to connect the railways of the southern and northeastern section of Brazil.

Brazilian steel capacity at present only provides about 35 per cent of Brazil's needs, but this capacity will be nearly trebled when the Volta Redonda plant, 80 miles inland from Rio de Janeiro, begins operations late in 1944 or early 1945. Compania Siderurgica Belgo-Mineira was founded in 1921, beginning operations at Sabara and later at Monlevade. In 1939, with a steel ingot capacity of 85,000 tons per year, this company represented 60 per cent of Brazil's total ingot capacity of 114,000. Steel ingot capacity in 1941 in Brazil was 155,000 tons per year, to which will be added an initial output of 275,000 tons per year when the Volta Redonda plant is put into production.

"PUT IT ON THE BLANCHARD"

Grinding Main Housing Poles for Magnetos on a No. 18 Blanchard Surface Grinder

Ability to remove metal quickly and cheaply makes it possible for Blanchard Grinding to carry through from roughing to finishing in one operation.

These Housing Poles for magnetos have .140" stock to remove from steel laminations. Ten pieces are held on a Blanchard designed fixture on the No. 18 Grinder and 30 pieces are finished per hour.

The weight and rigidity of the Blanchard are essential for economical machining of parts such as these.

WOMEN
(Yes, You!)
WANTED

. . . for easily-learned, well-paid jobs operating simple, safe Delta Machine Tools

— in war plants the country over

If you've been hesitating about war-plant work because you lack a blacksmith's biceps and a technical training, let us assure you that neither is needed. In war plants all over the country, there are Delta Machine Tools waiting for women just like you, offering pleasant jobs well within your capacity—good-pay jobs that give you the thrill of pride and financial independence.

You can do it!

Thousands of women everywhere are setting production records on Delta Tools, after brief instruction on the job. There's nothing complicated or hard about it.

The thousands of Delta Tools now used in war industry are built on exactly the same principles as those favored for twenty years in schools and hobby shops. Delta engineers have merely given them the extra strength, the super-accuracy, the automatic features needed for continuous operation.

Delta machines *had* to be safe — they were originally developed for use by school children and amateurs. They *had* to be simple, easy to understand. They *had* to be convenient, easy to operate without fatigue. And they ARE — today more than ever.

The time is NOW!

When you operate one of these Delta machines, you take your place behind our fighting men and speed them along the road to victory. And remember, every hour of delay in turning out the weapons of war must be paid for in American lives.

Take this ad to the nearest office of the U. S. Employment Service. Tell them *that's* the kind of war job *you* want — *now.*

Bison Earns Title Of No. 1 LCT Builder

North Tonawanda, N. Y.

• • • **Although winter** has closed navigation on the Great Lakes and the New York Barge Canal, production of LCT boats continues heavier than ever at Bison Shipbuilding Co. here. Instead of being shipped by waterway, the 157-ton vessels are dismantled, each packed on 11 freight cars, and sent to an East Coast for reassembly.

According to Lieut. Fred J. Bartell, assistant supervisor of shipbuilding for the Navy in the Buffalo district, Bison is the largest producer of LCT's in the country. Frank E. Ernst, company treasurer, says the Navy's order for the craft has been tripled and are now five times greater than those of any other firm. In 1943 Bison turned out five times more of this type of landing craft than any other company. Ten vessels are under construction at the Bison yard at all times. Facilities of two other companies, Ernst Iron Works, Inc., and August Feine & Sons Co., Buffalo, help build the boats.

The Gould coupler plant of Symington-Gould Corp. in Depew, Buffalo suburb, is turning out a heavy tonnage of steel for invasion craft, armored tanks, locomotives, and other heavy railroad equipment for the armed forces. One of the largest foundries in New York, this greatly-expanded coupler plant is operating under the pressure of military needs for invasion equipment, while much-needed railroad castings are being produced only in limited quantities under WPB allocations

Buick Tools to Build P & W Twin Row Wasp Engine

Flint, Mich.

• • • **Buick is tooling** to manufacture a cargo plane engine of the Pratt & Whitney twin row Wasp type. A 14-cylinder radial engine, developing 1200 hp., it is comparable in most parts with the Pratt & Whitney engine, being mass produced by Buick and others for the Liberator bomber program. A similar cargo plane power plant is built by Chevrolet.

The new production will be carried on in the Flint and Melrose Park, Ill., plants in which the bomber engines are manufactured, with many of the parts and sub-assemblies produced on the same machines and assembly lines.

SALEM CAN BUILD YOU ANY TYPE OR ANY SIZE OF

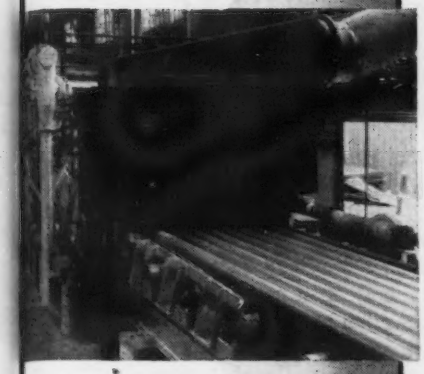
INDUSTRIAL FURNACES

● Salem designs heat treating furnaces to provide maximum operating efficiency for your specific manufacturing operations.

We can design and build any size or any type of heat treating furnace, gas, oil, or electric-fired, for either ferrous or non-ferrous material.

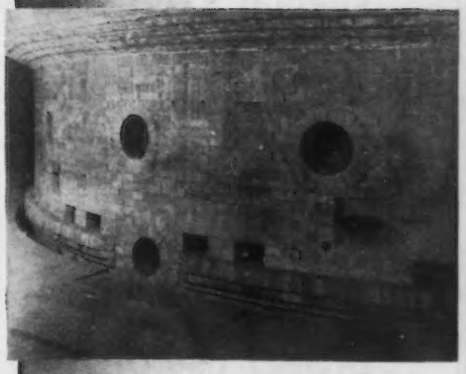
On this page we show current examples of Salem equipment, illustrating our scope, versatility, and experience.

When you need heat treating equipment, check the firm which will build the kind of installation you want . . . SALEM ENGINEERING COMPANY.



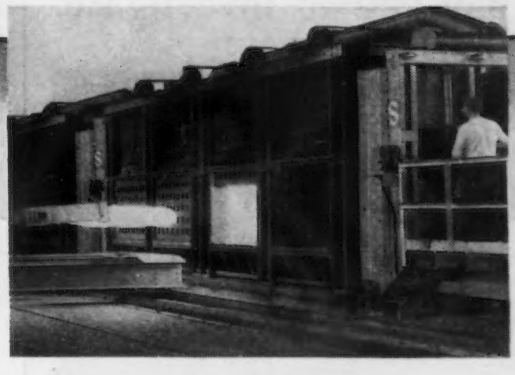
ular Furnace for Tubular Products

horizontal cylindrical furnace affords ex- nt heating uniformity between 800° F. and ° F. Designed to handle steel pipe, 2 to 14 es diameter.



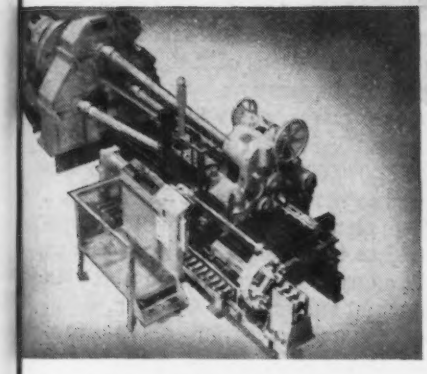
World's Largest Rotary Furnace

Billet Heating Furnace has a capacity of 80,000 pounds per hour at 2250° F. when heating 10" billets on a five hour cycle. Hearth area of 2100 sq. ft. is equipped with a variable speed mechanism which gives range of 2 to 8 hours per revolution.



Batch Type Furnace

Produces over 30 tons of alloy steel per hour at 2250° F. Handles either ingots, billets, or slabs. Equipped with Salem Needle Metallic Recuperator which preheats either gas or oil for greater combustion efficiency.

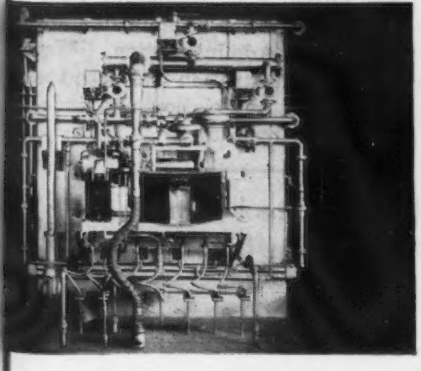


Salem's Witter Mill

is mill elongates and rolls shells to finished ing dimensions which eliminates much of the machining operation, saves material and man rs, provides low operating cost, plus min- m maintenance. Small floor space required.

Aluminum Annealing Furnace

Each furnace is built to individual customer specifications. In this furnace, a unique method of convection heating is applied for processing aluminum plates and sheets.



osphere Annealing With Direct Firing

with gas for an operating temperature of 1450° h capacity of 40,000 pounds of bar stock per . The heating and cooling cycle is 20 hours,

Circular Soaking Pits

They heat cold or hot carbon or alloy steel ingots 25% faster. Heat is obtained from a multiplicity of oil or gas burners.

Continuous Pusher Type Furnace

Has double chamber—one for hardening small fo ings or stampings and one for drawing. Both be used for normalizing.

Lake Carriers Study Manpower Problems

• • • A plan to recruit personnel and stabilize manpower on Great Lakes vessels to meet manning problems which might affect the coming 1944 shipping season was announced by ODT

The proposed program, if accepted, would provide for the recruitment of both skilled and unskilled seamen from groups not liable for immediate military service; cooperative control by the Recruitment and Manning Organization and the Coast Guard of all exits and entries of men in the industry; occupational deferment of officers and skilled men in selected age groups through RMO request; and the opening, where needed, of additional RMO offices to carry out the program.

Anticipation of increased tonnage movement by the Great Lakes carriers during the 1944 season makes an early solution of the manpower problem imperative. According to ODT estimates, some 90,000,000 tons of ore, 285,000,000 bushels of grain and 52,000,000 tons of coal are expected to move via Great Lakes lanes.

The plan as proposed will be presented to the Great Lakes industry as well as to the agencies involved in the actual operation of the plan. Final adoption and execution of the program is expected in the near future.

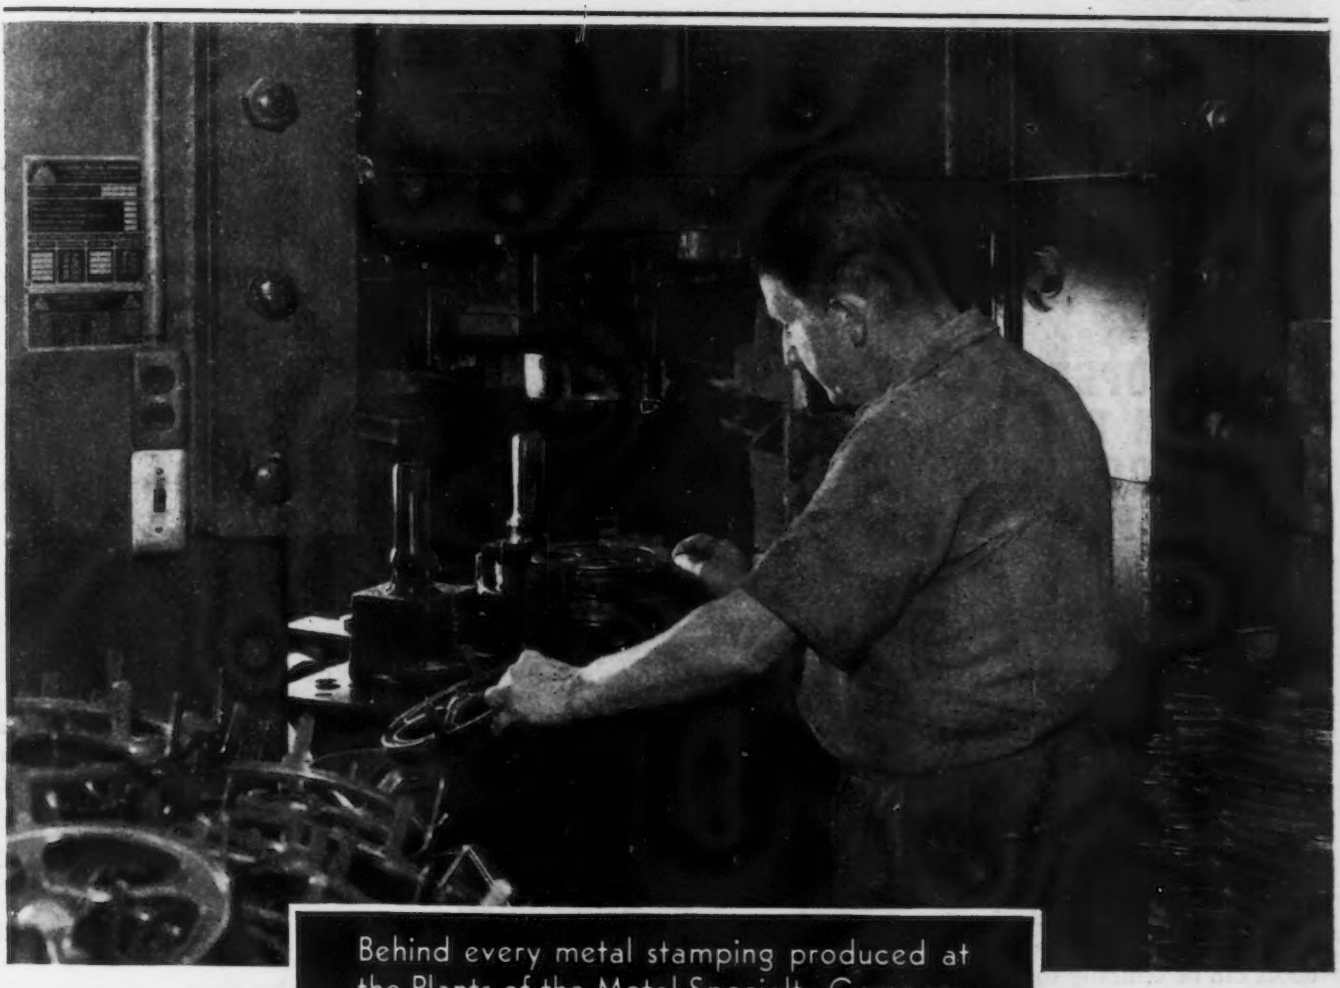
The meeting held to discuss the manpower problems was called by the ODT and included representatives from the War and Navy Departments, Selective Service System, War Production Board, War Manpower Commission, War Food Administration, Solid Fuels Administration, War Shipping Administration and both the Lake Carriers Association and independent Lake operators.

Pittsburgh Steel Earns $1,734,222 in 1944

Pittsburgh

• • • **Pittsburgh Steel** Co. reported preliminary earnings for the year ending Dec. 31, 1943, of $1,734,222, after all charges including provision for state and federal income taxes, and excess profits taxes of $3,140,000. For 1942 the company reported net earnings of $2,488,074. The company has signed an agreement with the Pittsburgh Ordnance Branch of the War Department to refund 1942 earnings of $515,000, to the government, which, after tax adjustments, will reduce net profit for 1942 by $97,850.

PRECISION STAMPING



Behind every metal stamping produced at the Plants of the Metal Specialty Company is a background of years of experience. This experience combined with an Engineering and Designing Staff of the highest calibre assures you not only the finest in Metal Stamping, but an efficient and authoritative Service for your specific problems. Metal Specialty serves Industry in Stamping, Coining, Forming, Drawing, Annealing and all types of Welding. Specialists in Hydraulic Cold Drawing and Embossing on all metals, including Stainless Steel and Aluminum. Deep Drawing and Embossing up to 850 tons capacity. Shells drawn up to 20" depth.

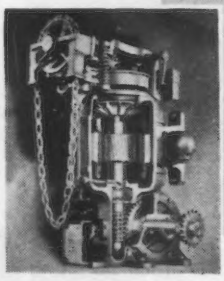
PRESS A BUTTON and DOORS OPEN for greater doorway economy!

MOTOR OPERATED KINNEAR ROLLING DOORS DO THESE THINGS FOR YOU!

They save time and labor—touching a button sends the door instantly on its way up or down. They save heating and air conditioning costs — ease of operation eliminates the tendency to leave the doors open. They operate more smoothly — with automatic operation there's no jerking or slamming, no rebound at top or bottom. They permit the use of remote control switches — doors may be operated from several convenient points, and any number of doors can be centrally controlled.

And the oftener the doors are used, the more these savings mean to you!



The Kinnear interlocking-slat construction has proved its efficiency and durability over a pediod of half a century. The sturdily-constructed curtain rolls smoothly into a neat coil overhead, out of the way of damage. When closed it presents a formidable steel barrier to theft or intrusion. Materials and merchandise may be stored within a few inches of the door at any point, saving floor and wall space. Kinnear Rolling Doors are made to order for any size or type of opening. For the answer to your doorway problem write for full details on Kinnear Rolling Doors. The Kinnear Mfg. Co., 1760-80 Fields Ave., Columbus 16, Ohio.

SAVING WAYS IN DOORWAYS **KINNEAR** ROLLING DOORS

Strike Vote Closes Chicago Foundries

Chicago

• • • **As a result** of the first strike vote taken in the midwest under the provisions of the Smith-Connally anti-strike law, 26 Chicago foundries, most of them gray iron but a few non-ferrous, were closed this morning by strike of Local 233, Molders and Foundry Workers Union AFL. Between 2000 and 2500 men are involved. At ten other foundries, represented by the Chicago Foundrymen's Association, no strike vote has been taken but it seems possible that workers may fail to report to work if the duration of the strike is long.

The inception of the difficulty occurred last November when the Regional War Labor Board denied a union pay raise request, a decision subsequently confirmed by the National War Labor Board at Washington. This was followed by an NLRB sponsored election, which resulted in a strike vote for Dec. 27. The strike was avoided at that time, however, when the foundrymen's association joined the workers in an application filed Dec. 30 for a six-cent per hour increase. This application was denied.

Kaiser May Operate Ohio Plant

Cleveland

• • • **The Henry J. Kaiser** empire is again thought to be spreading eastward, judging from a report that he will soon take over the largest of nine production lines of the Scioto Ordnance plant at Marion, Ohio, for the production of incendiary bombs under the operation of his Permanente Metal Corp.

About 400 employees may be required, about 60 of which may come from the Permanente organization in California. Operation of the portion of the plant to be held by Kaiser will be for the Chemical Warfare Service, it is understood.

Bell Retools for New Models

• • • **New machinery** installed and retooling completed, Bell Aircraft Corp.'s Niagara Frontier Division plants will begin immediately the production of two new models. About 2000 additional employees will be required. Production on P-39 Airacobras will halt when current contracts are completed and all facilities devoted to the new production, details of which remain in the confidential stage.

Perfected through testing

J. W. Frazer Reported Buying Warren City Tank & Boiler Plant

Cleveland

• • • **Reports of negotiations** for the sale of the Warren City Tank & Boiler Co., property at Warren, Ohio, to Joseph W. Frazer, former president of Willys-Overland Co., were confirmed. These negotiations involve only the holdings of the Taylor-Winfield Corp., parent concern, which constitute only the value of the old Warren City plant prior to an extensive Navy expansion program at the plant. While the deal had not been concluded, it appeared to be progressing since Mr. Frazer recently formed an Ohio corporation believed to be known as the Warren City Mfg. Corp., to operate the facilities.

The plant is now making landing barges, but previously produced diesel engine bases. Mr. Frazer's eventual plans after Navy contracts are satisfied, while reported as centering around farm machinery and similar equipment, have not yet been officially disclosed.

Warren City Tank & Boiler Co. was once an independent, later a holding of Taylor-Winfield Corp., and more recently almost entirely Navy property. Further complications to present negotiations might occur because of the condemnation proceedings which were filed against certain company properties by the Navy last fall.

ANOTHER ORIGINAL AJAX DEVELOPMENT!

THE ISOTHERMAL HEAT-TREAT PROCESS

Battery of Ajax-Hultgren electric salt bath furnaces for Isothermal Treatment of SAE 4140 alloy steel parts: Hardening Bath 1550° F., Quench Bath 700° F., Draw Bath 1000° F.

1. ELIMINATES QUENCH CRACKS
2. REDUCES DISTORTION
3. AVOIDS SCALE AND DECARB
4. INCREASES TOUGHNESS WITH SAME HARDNESS

Isothermal quenching in this process gives results superior to the conventional quench-and-temper method of treating carbon-alloy steels. Stresses that produce quench cracks and distortion are eliminated. For the same final hardness the physical properties, such as ductility and tensile strength, are improved (as much as 25,000 psi in some cases).

This three-step salt bath process consists of austenizing in the first unit, followed by immersion in the isothermal quench for transformation, and then immediate transfer to the final draw bath—all three steps occurring in a rapid and uniform cycle.

With this Ajax 3-step process, the "S" curves (Time-Temperature-Transformation) are now translatable directly into practice by any heat treater. This is important because until now no production equipment was available for doing what Time-Temperature-Transformation data shows clearly can be done.

Investigate the wide range of usefulness opened up by freedom from limitations of the conventional quench-and-temper method. Send for the simplest practical exposition ever offered on this subject: "Isothermal Quench Bath: Theory and Practice." It will be sent free on request.

NOTE: We are prepared to treat specimen products by this new process for direct comparison.

ADVANTAGES of Positive Displacement

Roots-Connersville Rotary Positive Blowers and Gas Pumps have lowest power consumption per cubic foot of air delivered at moderate pressures. Noted for exceptionally long life and ability to carry emergency loads in excess of rated capacities.
Twin impellers alternately suck in, momentarily entrap, and then expel definitely measured amounts of air or gas, resulting in the delivery of four equal pre-determined volumes each revolution of the drive shaft. Impellers need no seal or lubrication. Capacity varies with speed. Pressure automatically builds up to overcome resistance on discharge side. "R-C" Units are extensively used for cupola blast; coal preparation; smelting and treatment of ores; chemical processes; boosting air and gas pressures to ovens, forges, and heat treating furnaces; pneumatic conveying of bulk materials; agitation and aeration of liquids, etc. Write for Bulletin.

Ford Motor Co., Dearborn, Mich., to provide additional machinery and equipment at a plant in Detroit, at a cost in excess of $50,000, making a total commitment of more than $2,350,000.

•

General Chemical Co., New York, construction and equipment of facilities at Front Royal, Va., at a cost in excess of $1,500,000.

•

Pittsburgh Forging Co., Pittsburgh, to provide additional equipment at a plant in Coraopolis, Pa., at a cost in excess of $100,000, making a total commitment of more than $300,000.

•

Lederle Laboratories, Inc., New York, to provide additional equipment at a plant in Pearl River, N. Y., at a cost in excess of $65,000, making a total commitment of more than $300,000.

•

The Budd Wheel Co., Detroit, to provide equipment and machinery at a plant in Detroit, at a cost in excess of $60,000.

• • • **The War Department** announced:

Atlanta Ordnance Depot, Georgia, authorization in amount of $500,000 for reconstruction of base shop and warehouse. Work will be supervised by the Savannah, Georgia, District Office of the Corps of Engineers.

•

Benicia Arsenal, Cal., to build additional facilities for storage, repair, and micellaneous operational uses. Initial authorization is in amount of $600,000. Work will be supervised by the San Francisco, Cal., District Office of the Corps of Engineers.

•

830th Army Air Forces Specialized Depot, Memphis, Tenn., to build three additional warehouses with minimum essential utilities. Initial authorization is in the amount of $500,-Ala., District Office of the Corps of Army En-Ala., District ffice of the Corps of Army Engineers.

•

Dow Magnesium Corp., Midland, Mich., to provide additional equipment at a plant in Velasco, Tex., at a cost in excess of $180,000, making a total commitment of more than $61,800,000.

•

The Ohio Steel Foundry Co., Lima, Ohio, to provide additional facilities at a plant in Lima at a cost in excess of $90,000, making a total commitment of more than $3,800,000.

•

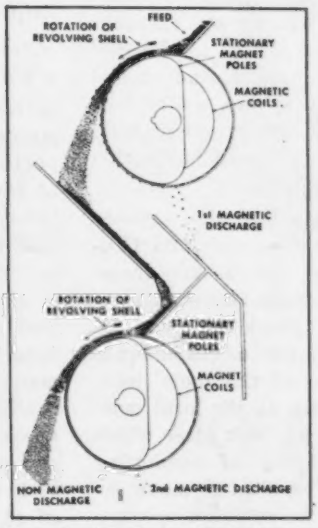
The Firestone Tire & Rubber Co., Akron, Ohio, to provide additional facilities at a plant in Atlanta, at a cost in excess of $130,000, making a total commitment of more than $740,000.

Dings

MAGNETIC DRUMS

. . . Specially Developed to Meet Requirements of the Metal Working Industries!

Principle of Operation
Cylindrical shell revolves around stationary magnet coil. Magnetic particles are held to shell surface until they pass out of magnetic field. Non-magnetic passes over drum in normal trajectory.



The illustration above, left, shows a Dings Double Drum Separator purifying aluminum turnings at the East Chicago, Indiana, plant of U. S. Reduction Company. Diagrammatic sketch of operation shown at right.

DINGS Magnetic Drums and Drum Type Separators for such jobs as removing iron from foundry sand or non-ferrous scrap are completely automatic, simple, and fit in ideally where space is limited. Capacities of standard size drums range from 300 to over 6000 cu. ft. per hour on scrap and sand. Single magnetic drums may be installed at the bottom of chutes, or single and double drum separators enclosed in housings and equipped with hoppers are available. For handling hot sand, drum coils can be wound with glass covered wire to withstand high temperatures. For badly entangled particles, agitating drums are built to combine magnetic attraction and mechanical agitation for maximum separation. Complete data, diagrams, tables, etc., are contained in Dings Catalog No. 660 available on request.

At the left is a Dings Type XM Drum Separator separating ferrous and non-ferrous machine shop scrap. A compact, powerful unit for borings and turnings.

ALNICO TEST MAGNET
Now available — horseshoe type magnet. Very powerful. Size 2½" high x 3" wide. Pole bases ¾" x ¾". Prices on request.

MACHINE TOOLS

. . . News and Market Activities

Machine Tool Executives Sight Bright Ray in Modernization Needs

(*Continued from Page* 104)

original "sale" prices. This, likewise, would give the ultimate purchaser a centralized point from which to buy specific machines at less than list costs of new machines yet with a factory guarantee and service policy. For the machine tool builder who will deal exclusively in the machines of their own manufacture it presents an opportunity to protect their reputations and supply employment for their own sales and service staffs despite an otherwise poor market.

Questions relating to what activities the machine tool builders will participate in during this period of redisposition of excess equipment have brought the following conclusions:

Builders are expected to find a fair volume in specialized machines for postwar purposes. New attachments and re-tooling of existing equipment will supply some work as will the maintenance of repair part stocks. Rebuilding programs which have been a source of income even during the current period are expected to be continued. Redesigning is also expected to produce a number of extremely low cost machines which will appeal to a part of the market not heretofore seriously considered.

Subcontracting appears to be a very fertile field for the machine tool builder who has engaged in such contract work extensively during the current period. This work is expected to be drawn from producers of civilian products which will be in flood demand after the war and who do not wish to expand their own facilities for the brief period of the rush demand.

The immediate desires of the industry appear to be that a government board, constituted especially to control the redistribution of excess materials, be appointed at an early date and that its policy be put into effect almost at once. This desire for action is brought on by the immediate need to begin the orderly process of redistribution being caused by cutbacks and cancellations. It is also hoped that this board will set a staunch and simple price and selling policy and clarify the part each government agency will play in the redistribution of machine tool equipment.

It has been suggested that present branch government agency and Ordnance offices and contractors themselves be used as sales outlets all operating under a single policy. All sales so far as possible might be made within the region of the tools' location until such time as the local market had absorbed its limit after which a national cataloging of remaining equipment might be used to move the remainder.

Through such a course the troubles of dumping on the market are thought to be reasonably well avoided. Speculation buying is also thought to be of little danger in that a bloated market would offer a minimum of profit possibility to any speculative buyer for years to come. Set prices for original purchase from the government would halt bargain buying for speculation and the return of a free market which might permit profitable selling of held blocks of equipment is believed too distant to tempt much speculative money.

•

Monarch Declares 75c. Dividend

• • • **The board of** directors of the Monarch Machine Tool Company, Sidney, Ohio, at their meeting on Feb. 8 declared a dividend of 75c. per share, payable March 1 to stockholders of record at the close of business Feb. 19.

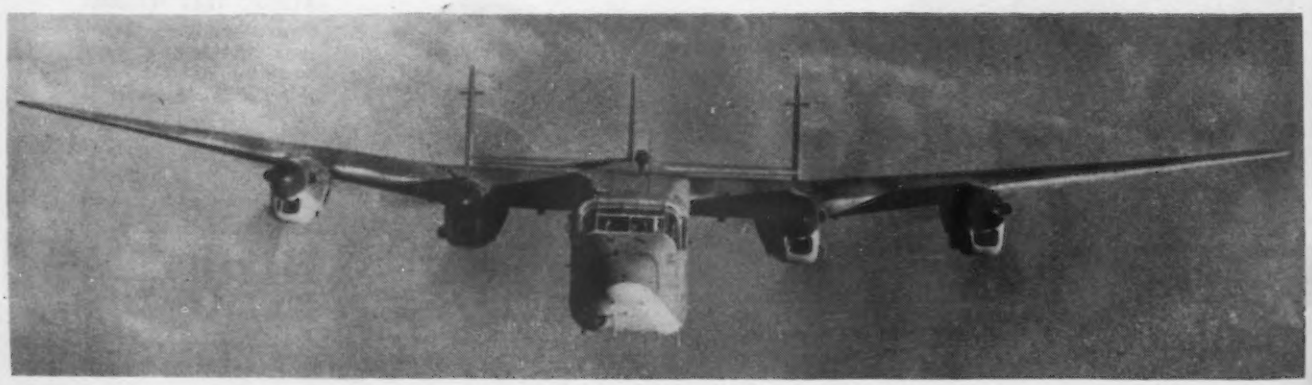
•

Inquiries for Postwar Projects

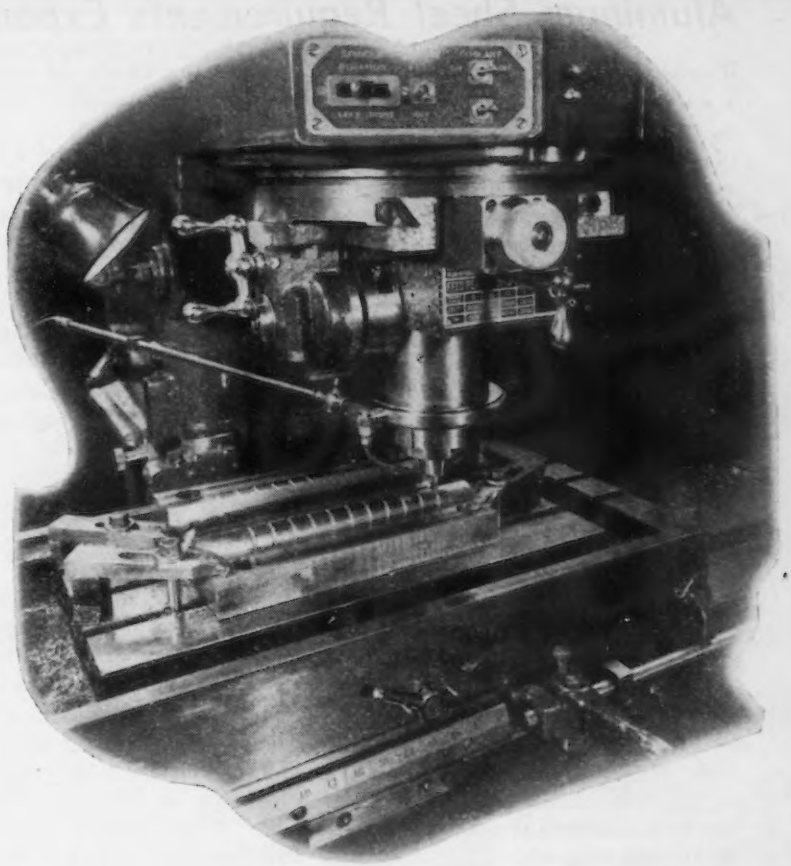
Cincinnati

• • • **Manufacturers generally** indicate that there has been quite a substantial quantity of inquiries, a large portion of which are for postwar work or for reconversion to civilian operations, but because of Washington's stiff attitude on priorities, attention is not being given to these inquiries in any great degree at this time. Attention, of course, has also been brought to bear upon the foreign demand which manufacturers indicate probably will not be within Lend-Lease provisions, but none of this has yet materialized or developed into such a situation that it has definite effect upon the market. Production, by and large, is tapering, since backlogs are being rapidly cleaned up. Conversion to other types of manufacture and jobbing work is going ahead at good pace, but is still far from sufficient to employ all the facilities of local shops.

HEAD-ON VIEW *of the Avro-York in Air: Transport version of the Lancaster bomber is a high wing, four-engined monoplane with a wing span of 102 ft. and overall length of 78 ft. Powered by four Rolls Royce Merlin liquid-cooled engines.*

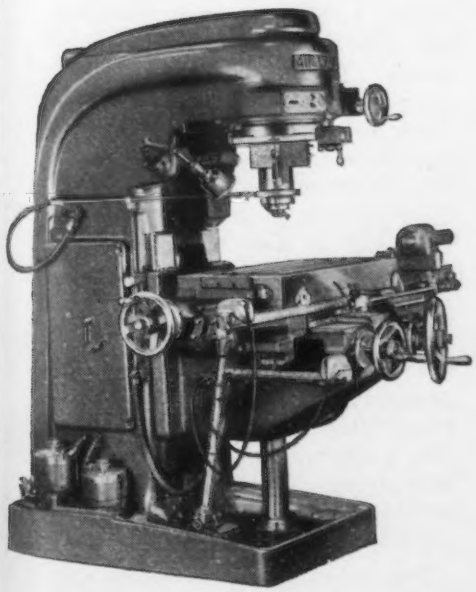


ROTARY HEAD MILLER . . . PLUS CHERRYING ATTACHMENT . . . SIMPLIFIES THIS "*TRICKY*" MILLING OPERATION



The Milwaukee Rotary Head Miller equipped with a cherrying attachment made "short work" of the "*tricky*" milling required on this injection mold. It took just two hours to complete the job — far less time than by any other method known.

The cherrying attachment is an auxiliary rotary head, mounted at 90° to the head of the miller. It is used to mill circles and angles in a vertical plane. When used with rotary head motion, spherical and conical cavities can be accurately and rapidly milled — in almost all cases difficult operations become a comparatively simple task.



KEARNEY & TRECKER'S ROTARY HEAD MILLER

The Most Versatile Machine Ever Designed for Mold and Die Work

DIRECT . . . mills mold cavities in a single set-up without the aid of templets or models.

ACCURATE . . . chances for error are eliminated because there is no change in set-up. Exact control of all combinations of cutting movements —possible only with this machine— transmits mathematical precision to the work.

FAST . . . initial job preparation and set-up time is reduced to the minimum. Accurate performance of the machine saves operator's time and rapid production of intricate molds and dies is the result.

Write for Bulletin No. 1002C for complete information on the Milwaukee Rotary-Head Miller and the accurate and rapid production of all types of molds and dies.

. . . News and Market Activities

Aluminum Sheet Requirements Expand

Washington

• • • **Philip D. Wilson,** director of the WPB Aluminum and Magnesium Division last Thursday issued a statement warning aluminum sheet producers that production must be stepped up immediately if 1944 requirements of the aircraft program are to be met.

Mr. Wilson cited the 60 per cent increase in airframe weight in 1944 over 1943, and decried rumors that there is an oversupply of aluminum sheet. He said:

"Just because there has been a reduction in aluminum pig production, a misunderstanding has arisen concerning our need for sheet. This is unfortunate, since there is no surplus in sheet. It is essential, therefore, that steps be taken not only to meet current increases in sheet requirements but also to prepare for greatly expanded requirements of this product expected later in the year."

Mr. Wilson also appealed to workers in sheet plants to stick to their jobs at this time so as not to endanger the aircraft program.

Rhodesian Copper Cut Studied

• • • **Sir Charles Hambro** and William L. Batt, British and United States members of the Combined Raw Materials Board, last week jointly issued the following statement in respect to Rhodesian copper:

"A recent announcement by the British Government of its intention to reduce copper production in northern Rhodesia has aroused considerable attention. Some reduction is desirable due to the fact that copper is competing with vitally needed coal and metallurgical chrome for the limited rail facilities in that area. The question of the magnitude of the cut in copper production is still under discussion by the CRMB and the British authorities.

"It is the view of the CRMB that although the copper position has improved in recent months, the uncertainties of future production and military requirements are such that the United Nations should proceed cautiously with any program to reduce output or relax consumption.

"When the determination of the extent of the Rhodesian reduction has been made, a statement will be forthcoming."

Bronze Powder Redefined

• • • **Flake type bronze** powder has been removed from the definition of copper and copper-base alloy powders for which it has heretofore been necessary to secure authorization to receive deliveries, WPB announced Feb. 11.

This action was taken by amending Copper Order M-9, which governs the acceptance of delivery of specified types of copper and copper-base alloy materials and copper-clad and copper-base alloy-clad steel scrap.

Reynolds to Get Haitian Bauxite

• • • **The Reynolds Mining Corp.** has been granted a 60-year concession by the Haitian Government to mine bauxite and other aluminum ores in the island republic. Renegotiations on behalf of the Reynolds company were conducted by Walter L. Rice, president of the mining company, with President Elie Lescot of Haiti over a period of several months. There followed months of prospecting for aluminum ore deposit by Reynolds geologists accompanied by geologists headed by Dr. Warren J. Mead from the Massachusetts Institute of Technology. Until the discoveries were made, there had been no indication that Haiti was a bauxite source.

The Haitian ore has entirely different physical properties from American and Guinea bauxite now used for aluminum production. Because of its unique properties—it contains an extremely low content of silica—the Reynolds geologists obtained President Lescot's permission to name it "Lescotite" as a tribute to the cooperation the Haitian authorities gave in making the concession a reality.

A party of geologists, headed by Dr. Walter L. Whitehead, was sent by Reynolds to the island republic last July to conduct field explorations. They worked under the general direction of Dr. O. C. Schmedeman, chief geologist of the Reynolds Mining Corp. The Haitian Government assigned Ing. Max Magones, of the Haitian Department of Travaux Publics, to accompany the exploration party. Captain Edouard Roy, head of the Haitian Air Force, piloted the party over a large section of the republic.

It was on one of these flights that Dr. Schmedeman detected signs of what appeared to be a large deposit of aluminum bearing ore in one of the mountain plateaus. The following day the geologists went to the area on horseback. They took samples and found them to be of good quality. Next, test holes were drilled and hundreds of samples were taken for analysis. Through the cooperation of Haitian officials this analytical work was performed in the laboratories of Haiti's School of Medicine.

Because of the unusual nature of the ore, research and experimental work has been necessary for its utilization in the production of aluminum. This work has been carried on in Reynolds Metals Co. laboratories at Listerhill.

Transportation facilities in Haiti are not of the best. However, the fact that some of the deposits are only three miles from the sea, and fortunately, the same distance from a potential deep water port, has made the transportation problem fairly simple. The ore can be brought to shipside by means of an aerial bucket chain, a method which will reduce materially the transportation cost, a most important factor in bauxite mining and aluminum production. Haitian labor will be used for most of the work on the mining project.

No Reports for Nickel Scrap

• • • **Generators of nickel** scrap and secondary nickel have been relieved of the necessity of filing report forms. This action was taken on Feb. 10 by WPB to reduce paper work, and was effected by the revocation of Supplementary Order M-6-c.

The revocation of this order does not in any way relax the control on or segregation of nickel bearing ferrous scrap which is still covered by Supplementary Order M-24-c or the use of nickel, including scrap and secondary nickel, which is still covered by Conservation Order M-6-b.

SCRAP

. . . News and Market Activities

Easing of Scrap Supplies Weaken Price Structure

New York

• • • **With the general** easing of scrap supplies throughout the country, there are growing evidences that the OPA scrap price ceilings will no longer act as minimum as well as maximum standards on prices. Low phos and alloy turnings and borings have been selling at under ceiling prices in various consuming markets for some months. As the alloy scrap stocks began to pile up at mills and scrap yards and the demand sloughed off, consumers refused to pay the premiums and dealers were more than willing to forego top prices so as to work off their growing stocks.

Rail Scrap Price Differentials Set by O.P.A. Details on Page 105.

However, past West Coast under ceiling sales of melting grades are supplemented by evidences this week from the Detroit area that some blast furnace grades are selling at as much as 50c. per ton under the ceiling. This may be the finger pointing to a general breakdown of scrap prices, with prices falling off in various localities on specific types of scrap, depending upon the local conditions. However, an across the board drop in prices, that is, a downward revision, in all grades, throughout the country is very unlikely. There will continue to be shortages in specific types of scrap, such as broken cast grades, through to the end of the war. As long as the steel production rate holds up to its present high figure, there is little likelihood of any sweeping slash in scrap prices.

Yard help is the biggest problem of the scrap dealers, and there is little hope that the shortage of manpower will be eased in this industry. However, this week the heavy snows in the east further hampered yard operations and incoming scrap just piled up for the already harassed yard operators to handle. While a year ago, predictions were made that scrap shortages might hinder steel production, shortages never reached such an acute stage. Now, however, scarcity of manpower in scrap yards may accomplish what scrap shortages couldn't.

The situation regarding scrap shipments from the West Coast has been clarified to the extent that new allocations from that area to midwestern and eastern mills will amount to about 70,000 tons as reported in THE IRON AGE last week. Of this, apparently 40 or 50 thousand tons have been allocated to three Chicago mills. Other shipments will go to Sheffield at Kansas City and St. Louis, Republic at Canton, and other mills. This material will be shipped via government land grant railroads on government bills of lading, mills being unwilling to take it on any other terms.

Price Increase Proposed

• • • The Scrap Iron and Steel Industry Advisory Committee to OPA is reported to have proposed a $1 increase for the breaking of cast scrap, which would raise the price from $2.50 to $3.50 per ton.

•

CHICAGO — Bad weather already has been reflected in decreased incoming scrap shipments here. Revisions of scrap ratios on alloy melts has not improved alloy market, mills having adequate stocks without having to make purchases.

•

DETROIT — Machine shop turnings, particularly alloys, continue weak in this market, selling as much as $1 per ton below ceilings. Some blast furnace grades also are selling 50c. below the tops. Cast grades, broken up, continue tight although unbroken heavy cast is in fair supply.

•

PHILADELPHIA — Although bad weather has stopped shipments, mills here are well supplied. Because of delayed furnace repairs, one mill has stopped most scrap shipments. Inventories have been increasing slowly. A boatload of some 60 15 to 30-ton Army tanks were sold Feb. 12 at $10.50 a gross ton.

•

PITTSBURGH—Adverse weather conditions are expected to effect scrap shipments here by the end of this week, although no serious results will materialize. Heavy melting grades appear to be in good balance, with several sources here actively buying. Carbon steel turnings are easier than a week ago, and shipments are coming from New England and Detroit areas. Turnings from Detroit are being sold here at the spring board price.

•

CLEVELAND — The market here did an abrupt about face last week with some brisk local buying of open hearth grades, resulting in somewhat of a tight situation. This is the first local buying of any consequences for some time, but follows the trend of buying in other parts of the country. Alloys continue in excess and in poor demand, although three-alloy scrap is reported to be moving once again, as a result of the recent government order increasing alloy scrap charges in both open hearth and electric furnaces. Prices are mainly being sustained with exceptions in the cases of turnings and alloys.

•

CINCINNATI—Machine shop turnings are definitely weak in the current market, as mill consumers are reported to have cut down requirements. There appears to be enough material to keep the market balanced between supply and demand, although heavy steel grades and cast iron grades are still hard to get. Alloys continue to be a surplus item.

•

BOSTON — Yards report production scrap supplies declining, with indications of a further drop. Other kinds of scrap are scarce, more particularly breakable cast for which there is a big demand. With the scrap supply and labor outlooks so uncertain, one of the largest yards operating two presses has sold one. Two other yards with presses have not operated them so far this month. Brokers report February shipments to date well under those of January. The January showing was the poorest on record in many cases.

•

BUFFALO—Dealers report very little scrap coming out but mills are well supplied. The district's largest consumer has passed the critical stage after operating on scanty reserves. Yard men expect the mild winter will result in an early navigation season with much scrap coming in by lake freighter and canal barge. Premiums continue to be waived on alloys, but no hint of below-ceiling sales on regular grades has appeared.

•

BIRMINGHAM — A downward trend continues here in the demand for scrap. Mill inventories are plentiful despite small movement of material to dealers' yards.

•

ST. LOUIS—A snow fall halted collection and handling of scrap in this area. The sale of borings and turnings shipped to Chicago and eastern markets at $1.50 to $2 below ceiling prices is reported. Railroad offerings have been light.

IRON AND STEEL (OTHER THAN RAILROAD) SCRAP

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles; No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing point (cents per gross ton) are: Chicago, 84c.; Pittsburgh, Brackenridge, 55c.; Detroit, 53c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, Pittsburg, 42c.; Seattle, 38c.; Buffalo, Claymont, Harrisburg, 36c.; Atlanta, Birmingham, 32c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Phoenixville, Bethlehem, Kokomo, Duluth and St. Louis, 28c.; Alabama City, Ala., 26c.; Minnequa, Colo., 22c.; Middletown, 14c.; Conshohocken, Sparrows Point, 11c.

*Basic open hearth and foundry grades, and auto springs and crankshafts, deduct 80c. per ton.

BASING POINT includes switching districts of city named.

Basing point	Switching districts:
Pittsburgh	Bessemer, Homestead, Duquesne, Munhall, McKeesport
Cincinnati	Newport
St. Louis	Granite City, E. St. Louis, Madison, Ill.
Chicago	Gary
Claymont	Chester, Pa.
San Francisco	So. San Francisco, Niles, Oakland

MAXIMUM SHIPPING POINT PRICE: Where shipment is wholly or partially by rail or vessel, or combination of rail and vessel, the scrap is at shipping point when placed f.o.b. railroad or f.a.s. vessel. For motor vehicle shipments scrap is at shipping point when loaded. Then maximum shipping point price shall be: (a) For shipping point located within a basing point, prices shown in above table for scrap at basing point in which shipping point is located, minus applicable switching charge deduction shown in paragraph above labeled "Switching Charges." (b) For shipping points outside basing point, price listed in above table hereof for scrap at most favorable basing point, minus lowest charge for transportation from shipping point to such basing point by rail or water carrier or combination. Where vessel movement is involved, in lieu of established dock charge or any cost customarily incurred at the dock, 75c. per ton must be included as part of deduction in computing shipping point price; 50c. at Memphis; $1 at Great Lakes ports; and $1.25 at New England ports. If no established transportation rate exists for a portion of movement from shipping to basing point, actual charge or cost customarily incurred by shipper in such portion of movement shall be included as part of deduction in computing shipping point price. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding prepared scrap. In no case, however, shall electric furnace, acid open hearth and foundry grades be used as the corresponding prepared scrap. A preparation-in-transit charge for unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced less $2; 75 to 85% Fe less $4; under 75% Fe less $8 per ton. Mill scale less $8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1% oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5% oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c. mill scale, $8 less than No. 1 heavy melting.

RAILROAD SCRAP

CAST IRON SCRAP

	Group A	Group B	Group C
No. 1 cupola cast	$18.00	$19.00	$20.00
Clean auto cast	18.00	19.00	20.00
U stripped motor blocks	15.50	16.50	17.50
Stove Plate	17.00	18.00	19.00
*Heavy Breakable Cast	15.50	16.50	17.50
Charging Box Size Cast	17.00	18.00	19.00
Misc. Malleable	20.00	21.00	22.00

Group A includes Montana, Idaho, Wyoming, Nevada, Utah, Arizona and New Mexico. Group B—North Dakota, South Dakota, Nebraska, Colorado, Kansas, Oklahoma, Texas and Florida. Group C—States not named in A and B; switching district of Kansas City, Kan., Mo.

Effective Dec. 14, 1943, dealers no longer absorb freight from point of origin to yard for preparation to No. 1 Cupola Cast.

* Preparation charge allowable, see order.

Tool Steel Scrap Prices (MPR 379)

SEGREGATED	Solids Per Lb. Cont. W	Turnings Per Lb. Cont. W
Type 1. 12% min. W, 1% max. Mo	$1.80	$1.60
Type 2. 5 to 12% W, 1% max. Mo	1.60	1.40
Type 3. 1 to 5% W, 1.5% max. Mo	1.25	1.25
*Type 4. 7% min. Mo, 2% max. W	0.125	0.105
*Type 5. 3.5 to 6% Mo, 4.5 to 6% W	0.135	0.115

UNSEGREGATED SOLIDS	UNSEGREGATED TURNINGS
$1.50 per lb. contained W if 5% or more.	$1.30 per lb. contained W if 5% or more.
$1.15 per lb. contained W if 1 to 5%.	$1.00 per lb. contained W if 1 to 5%.
$0.80 per lb. contained Mo if 1.5% or more.	$0.70 per lb. contained Mo if 1.5% or more.

If both W and Mo are within ranges, payment may be for both W and Mo content.

*Per lb. of scrap material.

If segregated, a premium of $1.50 per lb. of contained Co allowed if Co content is 3% or over. No scrap considered segregated if Co content ranges between 0.5 and 3%.

If Cu or Ni content over 0.25%, price shall be reduced by 50%.

If 500 lb. or less is sold, either segregated or unsegregated, price shall be reduced 2c. per lb. of scrap material.

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto, Ohio; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.; Sheffield Steel Corp. $2.55 St. Louis.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo, Colo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—Sheffield Steel Corp. $2.75 St. Louis; W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery in U. S. except Texas and Oklahoma may use Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. when shipped outside Alabama, Mississippi, Louisiana, Georgia, Florida, Tennessee, Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base granted on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base granted on Kokomo, Ind., product; Superior Sheet Steel Co. granted Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras showr are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1999 lb.; strip, extras on all quantities; bars, 1500 to 39,999 lb.; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. (10) 400 to 3999 lb. (11) 300 to 4999 lb. (12) 300 to 10,000 lb. (13) 400 to 14,999 lb. (14) 400 to 39,999 lb. (15) 1000 to 39,999 lb. (16) 1500 to 39,999 lb. (17) 2000 to 39,999 lb. (18) 3500 to 39,999 lb.

(*a*) Philadelphia: Galvanized sheets, 25 or more bundles.

Extra for size, quality, etc., apply on above quotations.

CAST IRON WATER PIPE

Per Net Ton

6-in. and larger, del'd Chicago.... $54.80
6-in. and larger, del'd New York... 52.20
6-in. and larger, Birmingham 46.00
6-in. and larger f.o.b. cars, San Francisco or Los Angeles 69.40
6-in. and larger f.o.b. cars, Seattle. 71.20

Class "A" and gas pipe, $3 extra; 4-in. pipe is $3 a ton above 6-in. Prices shown are for lots of less than 200 tons. For 200 tons or over, 6-in. and larger is $45 at Birmingham and $53.80 delivered Chicago, $59.40 at San Francisco and Los Angeles, and $70.20 at Seattle. Delivered prices do not reflect new 3 per cent tax on freight rates.

LAKE SUPERIOR ORES

(51.50% Fe, Natural Content, Delivered Lower Lake Ports)*

Per Gross Ton

Old range, bessemer, 51.50 ..... $4.75
Old range, non-bessemer, 51.50..... 4.60
Mesaba, bessemer, 51.50 ..... 4.60
Mesaba, non-bessemer, 51.50 ..... 4.45
High phosphorus, 51.50 ..... 4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

Inside this Cover is a "Can't Be Done"

that *WAS* done!

It is not a claim but a plain, unvarnished truth that Apex heavy-duty aircraft universal joints combine:

Highest strength (axial and torsional) weight ratio obtained to date;
Greatest resistance to fatigue and vibration;
Longest service life;
Permanently sealed-in lubrication;
Fully meet AAF "Winterization" directives.

The cover, an exclusive Apex development, makes the lubricant integral with the joint and lengthens its life by reducing wear and vibration, the two worst enemies of joints in service.

Now used in crucial controls of both Army and Navy combat aircraft, these Apex joints have achieved a highly improved strength-weight ratio over previous types in their field and have widened the usage of universal joint applications. They exceed all requirements of the current AAF Specification for Class 2 Universal Joints, and AAF Standard Sheet No. 271.

Five sizes are available with torque ratings up to 10,000 inch pounds. Your request for any desired data will receive prompt attention.

*Includes annealing and pickling.

This is no time for

EXCESS INVENTORY!

These days of cancellations, cutbacks, and design changes are hardly the time to increase surplus inventories. It's timelier to start streamlining your stocks — to get them "fluid" for future operations.

For example, why not reduce your inventory by buying a larger percentage of your steel requirements from warehouse? Frasse stocks of cold finished bars, tubing, stainless steel, alloy and aircraft steels and tubing are now in good shape. By buying from these stocks only what you need for immediate production, you avoid leftovers and dead material when contracts change.

Cancellations and cutbacks in your future operations may require quick action. Why be hampered with heavy awkward surpluses? Start reducing yours now by using Frasse inventories instead.

How many BULLETS in a battle?

Sources from the front say it isn't the quantity it's the accuracy. That checks with our ideas about springmaking, too. We work just as carefully on small orders for springs as we do on mass-production lots. There are many springs that may seem to suit your requirement — there's only **one** that meets all conditions of efficient manufacture and performance. Dunbar experience helps to select that spring — and to produce it efficiently and economically.

There's plenty of fight in springs made by

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable.

(2) Price shown is for low-phosphorous iron; high-phosphorous sells for $28.50 at the furnace.

(3) E. & G. Brooke Co. permitted to charge $1.00 per ton extra.

(4) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 per cent to 2.25 per cent); phosphorous differentials, a reduction of 38c. per ton for phosphorous content of 0.70 per cent and over; manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

LOOK FOR . . . and get . . . ALL THREE

THOROUGH engineering knowledge, wide and varied experience, ample fabricating facilities—each is important. Here you find all three. They helped build a reputation for competent service—brought assignments to build war factories, ships and drydocks for the Navy and Maritime Commission, unit construction bridges for the Army, numerous equipment items for war-busy plants. . . . Today, they are attracting forward-looking businessmen, who want counsel on problems of reconversion and future development. It's a practical idea—worth acting upon.

MISSISSIPPI VALLEY STRUCTURAL STEEL CO.

Engineering, Sales Offices, Fabricating Plants at Decatur, Ill. • Melrose Park, Ill. (Chicago Suburb) • St. Louis, Mo.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. For ton lots f.o.b. shipping point, in cents per lb.

Copper, electrolytic, 150 and 200 mesh	21⅛ to 23⅛c.
Copper, reduced, 150 and 200 mesh	20½ to 25½c.
Iron, commercial, 100 and 200 mesh, 96 + % Fe	13½ to 15c.
Iron, crushed, 200 mesh and finer, 90 + % Fe	4c.
Iron, hydrogen reduced, 300 mesh and finer, 98½ + % Fe	63c.
Iron, electrolytic, unannealed, coarser than 300 mesh, 99 + % Fe	30 to 33c.
Iron, electrolytic, annealed minus 100 mesh, 99 + % Fe	42c.
Iron, carbonyl, 300 mesh and finer, 98-99.8 + % Fe	90c.
Aluminum, 100 and 200 mesh	*23 to 27c.
Antimony, 100 mesh	20.6c.
Cadmium, 100 mesh	$1
Chromium, 150 mesh	$1.03
Lead, 100, 200 & 300 mesh, 11½ to 12½c.	
Manganese, 150 mesh	51c.
Nickel, 150 mesh	51½c.
Solder powder, 100 mesh, 8½c. plus metal	
Tin, 100 mesh	58¾c.
Tungsten metal powder, 98%-99%, any quantity, per lb.	$2.60
Molybdenum powder, 99%, in 200-lb. kegs, f.o.b. York, Pa., per lb.	$2.60
Under 100 lb.	$3.00

*Freight allowed east of Mississippi.

BOILER TUBES

Seamless Steel and Lap Weld Commercial Boiler Tubes and Locomotive Tubes, Minimum Wall. Net base prices per 100 ft. f.o.b. Pittsburgh, in carload lots.

	Seamless Cold Drawn	Seamless Hot Rolled	Lap Weld, Hot Rolled
2 in. o.d. 13 B.W.G.	15.03	13.04	12.33

PRICES

BOLTS, NUTS, RIVETS, SET SCREWS

Bolts and Nuts

(F.o.b. Pittsburgh, Cleveland, Birmingham or Chicago)

Machine and Carriage Bolts:

	Per Cent Off List
½ in. & smaller x 6 in. & shorter	65½
9/16 & ⅝ in. x 6 in. & shorter	63½
¾ to 1 in. x 6 in. & shorter	61
1⅛ in. and larger, all length	59
All diameters over 6 in. long	59
Lag, all sizes	62
Plow bolts	65

Nuts, Cold Punched or Hot Pressed:
(Hexagon or Square)

½ in. and smaller	62
9/16 to 1 in. inclusive	59
1⅛ to 1½ in. inclusive	57
1⅝ in. and larger	56

On above bolts and nuts, excepting plow bolts, additional allowance of 10 per cent for full container quantities. There is an additional 5 per cent allowance for carload shipments.

Semi-Fin. Hexagon Nuts	U.S.S.	S.A.E.
7/16 in. and smaller	..	64
½ in. and smaller	62	..
½ in. through 1 in.	..	60
9/16 in. to 1 in.	59	..
1⅛ in. through 1½ in.	57	58
1⅝ in. and larger	56	..

In full container lots, 10 per cent additional discount.

Stove Bolts

Packages, nuts loose	71 and 10
In packages, with nuts attached	71
In bulk	80

On stove bolts freight allowed up to 65c. per 100 lb. based on Cleveland Chicago, New York on lots of 200 lb. or over.

Large Rivets

(½ in. and larger)

	Base per 100 lb.
F.o.b. Pittsburgh, Cleveland, Chicago, Birmingham	$3.75

Small Rivets

(7/16 in. and smaller)

	Per Cent Off List
F.o.b. Pittsburgh, Cleveland Chicago, Birmingham	65 and 5

Cap and Set Screws

	Per Cent Off List
Upset full fin. hexagon head cap screws, coarse or fine thread, up to and incl. 1 in. x 6 in.	64
Upset set screws, cup and oval points	71
Milled studs	46
Flat head cap screws, listed sizes	36
Fillister head cap, listed sizes	51

Freight allowed up to 65c. per 100 lb. based on Cleveland, Chicago or New York on lots of 200 lb. or over.

RAILS, TRACK SUPPLIES

(F.o.b. Mill)

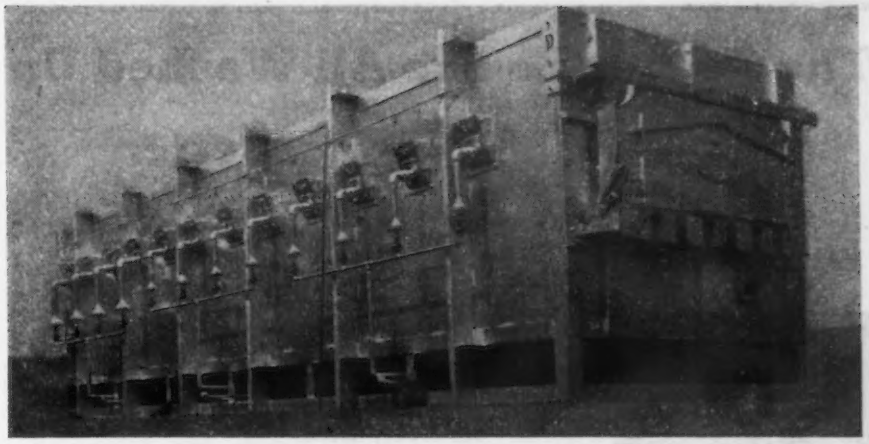
Standard rails, heavier than 60 lb., No. 1 O.H., gross ton	$40.00
Angles bars, 100 lb.	2.70
California Ports	3.15
(F.o.b. Basing Points)	*Per Gross Ton*
Light rails (from billets)	$40.00
Light rails (from rail steel)	39.00
	Base per Lb.
Cut spikes	3.00c.
Screw spikes	5.15c.
Tie plates, steel	2.15c.
Tie plates, Pacific Coast	2.30c.
Track bolts	4.75c.
Track bolts, heat treated, to railroads	5.00c.
Track bolts, jobbers discount	63-5

Basing points, light rails, Pittsburgh, Chicago, Birmingham; spikes and tie plates—Pittsburgh, Chicago, Portsmouth, Ohio, Weirton, W. Va., St. Louis, Kansas City, Minnequa, Colo., Birmingham and Pacific Coast ports; tie plates alone—Steelton, Pa., Buffalo. Spikes alone—Youngstown, Lebanon, Pa., Richmond, Oregon and Washington ports, add 25c.

ROOFING TERNE PLATE

(F.o.b. Pittsburgh, 112 Sheets)

	20x14 in.	20x28 in.
8-lb. coating I.C.	$6.00	$12.00
15-lb. coating I.C.	7.00	14.00
20-lb. coating I.C.	7.50	15.00



BELLEVUE FURNACES
are designed for the job.

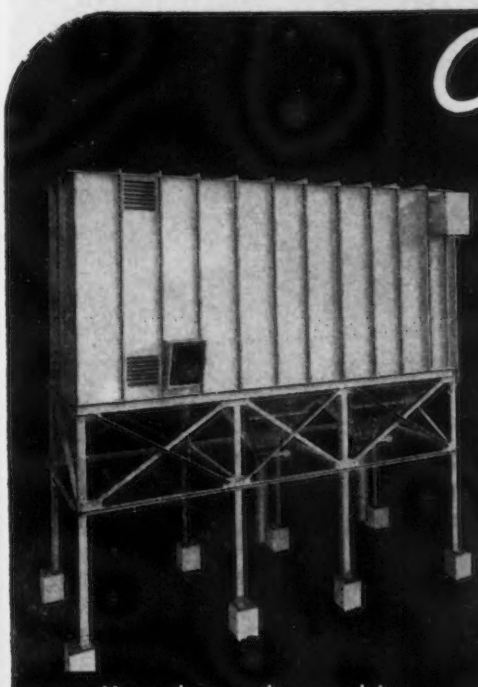
In the construction of Bellevue Furnaces, painstaking consideration of the job to be done comes first. Every factor must be evaluated, every condition studied. Only then do Bellevue engineers attempt design and recommendation of furnace type.

The soundness of that policy is being demonstrated in plant after plant. Hundreds of executives in scores of varied companies have proved, to their own satisfaction, the efficiency, speed, high production level and operating economies of Bellevues that were "designed" for the job.

You, too, will find Bellevue experience and facilities a profitable investment for your own furnace needs.

Send for full details.

BELLEVUE INDUSTRIAL FURNACE CO.
2974 BELLEVUE AVENUE DETROIT, MICH.



Control DUST!

FILTERED AIR
Avoids Dust Damage

Dust in your plant is both a *danger* and a *nuisance*, affecting employee health and causing damage to machines, equipment and buildings.

The Ruemelin Dust Filter gets rid of dust, easily and economically. It filters dust-laden air from tumblers, sand blast equipment, grinding wheels, crushers and other dust creating equipment. Reduces maintenance costs and shutdown periods. Reclaims all valuable dusts in processing chemicals, minerals, dyes, etc.

Ruemelin pioneered the highly efficient, tubular cloth bag filter. If you have a dust problem, let one of our experienced engineers help you. Ask for Cat. 24-C.

Also mfgrs. of Sand Blast Equipment, Welding Fume Collectors, etc.

RUEMELIN MFG. CO.
3870 N. Palmer St., Milwaukee 12, Wis.

More than a thousand installations prove Ruemelin Dust Filter superiority.

RUEMELIN DUST FILTER

The Sooner You're All Washed Up —the Better

● LOW PRODUCTION COST is a corollary to fast washing speed. Why? Because here is what happens: You spend less for power and labor time . . . other operating costs and fixed charges are spread over a greater volume of production . . . fewer machines are required, thus saving unnecessary investments in equipment and factory space.

The basic requirement for faster metal washing is quick and *complete exposure* of the work to the action of the sprays. And every machine of our manufacture has this element perfected to the 'nth degree—most of them, like the endless conveyor tumbling principle, being an original and exclusive development.

If you will write us we will gladly tell you more about these unique machines and how they will fit into your production.

METAL WASHING DIVISION

American FOUNDRY EQUIPMENT CO.

510 S. BYRKIT ST. MISHAWAKA, IND.

*The Tumbl-Spray machine, illustrated at left, is ideal for washing metal parts, stampings, and screw machine products. Write for Bulletin No. 9.

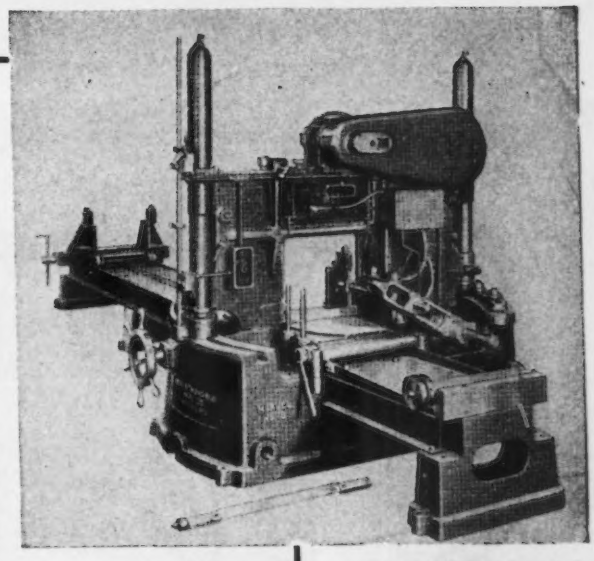
Ton lots	7.25c.
Simanal (approx. 20% Si, 20% Mn, 20% Al), contract basis, f.o.b. Philo, Ohio, with freight not to exceed St. Louis rate allowed, per lb.	
Car lots	8.75c.
Ton lots	9.25c.

CUTS the Toughest Steels and Largest Sizes *easily*.



This giant hydraulic metal - cutting saw is more than just a larger hack saw. It is a new development in metal-cutting methods that introduces a new principle of metal sawing — the Roll-stroke blade action makes it possible to cut the toughest steels in the largest sizes easily and rapidly. It also permits a simple and efficient, very low pressure Hydraulic Feed System.

Built for heavy work, completely enclosed in heavy housing, this machine will stand up under the rough usage of the average steel mill warehouse and forge shop, where it will speed cutting-off, and reduce material loss.

MARVEL No. 18
Giant Hydraulic Hack Saw
Capacity 18"x18"

Cuts angles up to 45° by simply swiveling upper machine housing.

High Temperature
INSULATION

SEMISILICA BRICK

In STEEL MILLS:

For Heating, Reheating, Annealing and Heat Treating Furnaces, OH Regenerators, Blast Furnace Stoves, Soaking Pits, etc. In the roofs, where spalling failure is most prevalent, they perform their greatest service.

In MANY INDUSTRIES:

Such as Chemical, Ceramic, Zinc Smelting and other industries where continuous heats in the temperature range of RM's are required for their processes.

Steadily maintained temperatures between 2200°F and 2700°F cause vitreous spalling of clay fire bricks. Shutdown and temperature changes are hard on Silica Bricks.

RM Brand Semisilica Bricks are the answer to many such furnace problems.

Use them in furnaces where temperatures are maintained high enough, and long enough, to cause "First Quality Clay Bricks" or "Super Duty Bricks" to "Vitrify and Spall" or to "Shrink and Deform," yet where shutdowns or severe temperature changes prevent satisfactory performance of silica bricks.

Approaching Common Ground

INDUSTRIAL economics has two branches. One has to do with the creation of values; the other with the division of the wealth represented by them.

The first of these two, the economics of creation of values is or at least should be a science as definite as arithmetic. It deals with multiplication and no one can argue with the multiplication table. As to the second, it will be subject to controversy as long as human nature exists.

In seeking to enlarge the common ground on which employers and workers can unite for their mutual welfare as well as for the good of the public, a large step will be taken when this distinction becomes recognized and acted upon. By reducing the area subject to friction in employer-employee relations we follow the simple laws of physics which tells us that the less the frictional area, the smoother and the faster the progress of any moving body.

It was for this reason that I suggested, in The Iron Age of March 18, 1943, the co-education of our future managers and labor leaders in economic fundamentals. To quote from this editorial: "Our future managers and labor leaders alike will largely be college graduates. It would be a good thing if they could go to school together, learn what the fundamentals are on which they can and should agree and how to settle that on which they cannot agree with the least possible friction."

It is encouraging to note that within the past few days, Cornell University has announced the establishment of such a course. And it is to be hoped that other universities and colleges will follow suit.

No one suffers from the creation of new values and new wealth but on the contrary all benefit by them. Enlightened labor leaders now accept this view as evidenced by the panel discussion on "Jobs in Peacetime" conducted by the National Association of Manufacturers, in which William Green and Philip Murray participated with Paul G. Hoffman and Frederick C. Crawford.

Symptomatic also of the new thought in this direction by both parties is the successful functioning of labor-management committees in many of our plants, which was brought about by common acceptance of the need to increase war production.

Getting together to study and discuss these things has an additional benefit going beyond the acceptance of the scientific approach to the economic problem. It is a course in human relations as well in which people get to know each other better. It is much easier to do business with people you know than with strangers.

Out of all this, I hope and believe, will come not only a better understanding of mutual problems but also a more tolerant and sympathetic attitude in handling those questions which being controversial cannot be solved by text book or slide rule.

Frames of track type tractors must resist terrific bending and twisting stresses.

Stronger Backbones for Tractors Using Inland Hi-Steel

Tractor frames must be strong—particularly those for track type tractors, which are turned by stopping one track, throwing terrific bending and twisting stresses onto the frame. That is why a manufacturer of tractors chose Inland Hi-Steel for the frames of their 10-ton track type Diesel tractors; Hi-Steel offers higher strength without added weight or size.

The original tractor design called for steel with 44,000 lb. per sq. in. yield strength. For the grueling service to which these tractors are subjected, especially when a bulldozer is mounted directly on the frame, it was found that greater strength was needed. Increasing the size of the frame section would have entailed complete redesign and sacrificing many desirable tractor features.

Inland Hi-Steel offered the perfect solution to the problem. Replacing the carbon steel channels with Hi-Steel, which has a yield strength of 57,000 lb. per sq. in., made possible retaining the same size and weight of frame, while increasing strength 29.5%. All design features were retained, and adopting Hi-Steel called for no change in fabricating methods. Thousands of these sturdy, powerful tractors in service confirm the dependability of the Hi-Steel frames.

Inland Hi-Steel, the corrosion-resistant and high-strength, low alloy, has established records for service and endurance on many of the toughest peacetime and wartime jobs. Today, most of the Inland Hi-Steel goes into war jobs but when peace comes, it will again be available for the construction of equipment in which higher strength, reduced weight and greater corrosion resistance are factors in product design, sale and service.

News Front

► A Swedish delegation is now in the U. S. trying to clear some shipments of pig tin and tin plate to that country, a movement that both the Germans and Allies may have different reasons for sanctioning.

The delegation is also attempting to lay plans for the recapture of pre-war steel outlets in this country. The desire is to ship high grade Swedish iron ore to the U. S. in payment for purchases.

► The continuous electrolytic tin plate line for wide strip, recently purchased here by British interests, is awaiting priority releases so that construction can start.

The Steel Co. of Canada has just about completed negotiations for an electrolytic tinning line, to be built in this country.

► Now that the pressure of the draft is biting deeper and war bond purchasing more insistent, there is a growing resentment in certain industrial areas to rank labor wastage in various war plants.

The policy of some plants seems to be to hire four people to do one job, probably as a deliberate means of keeping costs high. Workers themselves frequently complain, and campaigns to "make every minute count", or "buy bonds until it hurts", usually fall flat in such situations.

Some workers even decline to wear Army-Navy "E" buttons.

► USW's demand for higher pay before the WLB will probably be based on the AFL-CIO's cost of living study. Labor's survey insisted that the advance in the cost of living since the beginning of 1941 was 43.5 per cent, not the Bureau of Labor Statistics' figure of 23.5.

Anxious to get the case started, steel companies fear the cost of retroactive wage increases will not be recovered. Unofficial and speculative opinion as to amount of wage rise ranges from 7 to 10c. an hr.

► Greatest handicap to rehabilitation of war veterans is the many cases of psycho-neurosis, from shock caused by the rigors of training and actual war experience.

► Continuous casting of metals, for 100 years a dream of inventors, has within the past several years been adopted for the casting of practically all non-ferrous ingots and billets in this country. Costs are lower and the products are better.

For ferrous metals, interest in continuous casting is growing. Several different units are in experimental operation, but results to date are somewhat indefinite.

► Release and near-release of several large aircraft tooling jobs have filled Detroit tool shops. Some are not taking any new business now.

► Rumor has it that Buick will gradually become sole automotive manufacturer of cargo plane engines heretofore made only by General Motors in Detroit.

► Coating beryllium copper wire with silver increases surface electrical conductivity, reduces surface attack during heat treating and hardening and reduces wear on wire coiling tools. Little Falls Alloys, Inc., developed the new process.

► In spite of USES and WMC pressure and pleas in California for more workers, claims for unemployment insurance there are rising uncomfortably. There were 42,956 claims for benefits in September and 55,209 in December, an increase of 12,253.

► The Iron Fireman plant which burned down mysteriously in Portland will not be rebuilt. The management says it is impossible to supply the national market from a Pacific Coast plant.

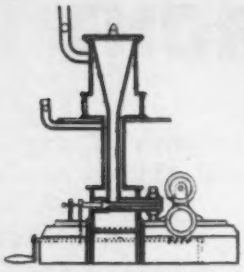
► With its Vulcan ore running as high 0.50 sulphur, the Kaiser Co. has purchased the Iron Chief Mine in the Eagle Mountains. RFC funds supplied a large part of the million dollars paid.

► Cartels are not the answer to domestic economic problems, Eric Johnson says. Increased postwar dispersion of industries will check the cartel movement.

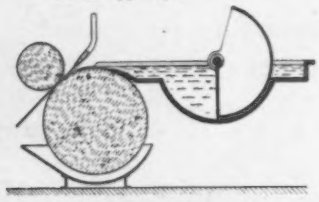
► With the lower Great Lakes free of ice, the 25 ships wintered at Milwaukee are receiving feverish preparation. Navigation is expected to open much earlier than the traditional April 15.

► Arrangements are now under way for the purchase of Bethlehem's boiler tube plant at Coatesville, Pa., by Lukens Steel Co., the plant's next door neighbor.

Continuous Casting



American Tube Casting, J. Laing, 1843



British Strip Casting, H. Bessemer, 1858

By T. W. LIPPERT

Managing Editor, The Iron Age

IT has been said that the cradle of every science is surrounded by dead theorists. And certainly there are innumerable examples of this in the metals industries. An excellent illustration, for instance, is the continuous rolling of metal, a tantalizing objective that for decades on end exhausted the efforts of a long line of famous, infamous and unknown inventors. And, finally, in 1922, John B. Tytus of Armco brought forth what now seems such an obviously simple scheme of a concave roll face, each stand of progressively less concavity. And, out of this one change in design sprang today's wide continuous mill rolling steel sheet, 100 inches wide, at 2000 ft. per min.

Another excellent example is the continuous casting of liquid metal into an intermediate form, preferably one requiring little subsequent breakdown. First, the casting of liquid metal alone was fascinating enough. Then, someone passed the cast metal directly into a rolling mill, and shortly thereafter this continuously rolled strip was passed directly into a stamping machine. This leitmotif of a continuous flow of metal from the liquid phase to a consumer end product, fast and inexpensive, and all housed within a small space, was enough to drive some 200 or so inventors into frenzy over the past hundred years. All the ideas, however, like mayflies, had only their brief afternoon of existence. They were born and they died on paper, as constant exemplification of that great void that always exists between cerebral production and commercial production.

Credit for starting the ball rolling is conventionally given to the famous Englishman, Sir Henry Bessemer, who early in 1858 suggested that the then successful rolling of glass plate between two rolls from the liquid phase could perhaps be adapted to a similar rolling of soft metals. Some ten years later he actually gave it a try, successfully rolling a 40-in. length of wrought iron strip, said to have excellent surface and metallurgical properties. But, Bessemer's idea (American patent No. 49,053) came long after a method of continuously casting soft metal tubing wherein the mandrel was vibrated to prevent sticking, conceived by J. Laing in 1843 (American patent No. 3,023). With nationalism in temporary eclipse, the proper crediting of the original ideas may not be of much importance at this late date. But, since today's commercial continuous casting processes resemble Laing's far more than they do Bessemer's, perhaps some of the accolade for being the father of continuous casting could be shifted from the shoulders of England's illustrious Bessemer to that of America's unknown Laing.

Following Bessemer and Laing, the next important twitch in the technology of continuous casting came during the period 1890 to 1900. In 1891, E. Norton and J. Hodgson successfully rolled some steel sheet by pouring liquid metal between two rolls. (For details see THE IRON AGE, April 11, 1940.) The results were promising, but work was abandoned due to lack of money and time. At about this same period the Washburn & Moen Mfg. Co., Worcester, became greatly interested in continuous casting of round billets. Washburn, Daniels and Stover of that company set down a number of excellent observations on such casting through a vertical water-cooled mold. A little later J. O. E. Trotz of the same company elaborated these ideas and is accredited with establishing some lasting principles of continuous ingot casting. But, no machine actually was ever built. Trotz became superintendent of the South Works of American Steel & Wire Co. (which had absorbed Washburn & Moen), and after some years retired to Sweden and died there some seven or eight years ago. Also, during this same period (1890), B. Atha (from which Atha Works of Crucible Steel Co.) built and commercially operated a vertical-mold continuous casting machine for turning out 4 x 4-in. high-carbon (1.15 C to 1.50 C) file steel ingots. This unit probably produced many thousands of tons of this file steel, and it was not abandoned until 1910, when crucible melting went into a decline. A single crucible was poured through the mold at a time, and the open mold shell itself (patent No. 425,846) was rather long but with no elaborate interior cooling innovations. Information available is that the surface of the ingot was none too good, but still fully satisfactory for commercial production. Furthermore, for some reason no steels other than the file analyses ever were so cast.

By 1900, practically every conceivable idea on continuous casting had been pawed over and set forth in patents by a long line of known and unknown inventors. There were infinite variations of casting the molten metal between metal rolls, with exquisite nuances of mold design, cooling technique and auxiliary equipment. The same applied to pouring between chains of half-molds carried on continuous belts, or of pressing, sucking and pouring of molten metal through all kinds of vertical, horizontal and slanted mold arrangements.

The next definite effort to actually physically cast metal came in about 1914. At this time, J. T. Rowley is supposed to have tried casting of steel through a vertical mold at the U. S. Horse Shoe Co., Erie, Pa. But a young man, fresh from college, by the name of Grenville Mellen, blew a surge of new life into the idea of casting between mold-halves carried on two continuous belts, first suggested in detail back in 1885 by A. Matthes and H. W. Lash. Remarkably little is known of the Mellen efforts considering the fact that the work didn't fold up until about 1925. During the period 1914-25, considerable financial support was given Mellen by Spencer Watters, of the New

. . . Swept along for 100 years on a wave of fascinating inventive vagaries, the continuous casting of liquid metals within these past five years has sprouted from an inchoate, diffident laboratory practice to a full-blown commercial technique. The bulk of coppers and brasses and practically all light metal production now pass through a variety of continuous casting equipment. And, in steel, no longer is the attitude one of cavalier disdain. Today, several machines are experimentally casting steel, and still another technique has continuously cast some thousands of tons of high-grade commercial ferrous alloys.

York Cotton Exchange. Mellen is probably still living, although where he is located this writer does not know.

Mellen came to the general machine shop of Thompson, Coates & McKay, of Harrison, N. J., early in 1913 to have a small horizontal chain machine built for casting solder. Attention was later shifted primarily to brass, and the machine in about 1914 was shifted to the Standard Underground Cable Co., Perth Amboy, N. J. During this interval the idea of a horizontal machine (see photo on page 50) was discarded in favor of a much larger vertical chain machine. In 1915, Mellen had his patents assigned to the Continuous Casting Corp., and the machines were all shifted to Gar Wood, N. J., where they became the seed from which grew the Gar Wood Brass Corp., a war enterprise of considerable size which completely disappeared from the industrial scene by 1925.

Mellen was a clever theorist and devised many improvements in the chain casting technique and metal feeding techniques. He also was quite an amateur athlete, and for years did a great deal of wrestling around eastern New Jersey as the "Masked Wonder," the mask being worn to conceal his identity. He usually won the matches, too.

A not very good photograph of the Mellen vertical chain casting machine is reproduced on page 51. The individual mold blocks (or half-blocks) were cast iron, about 5½ in. long and 5 in. wide. The machine was 12 ft. in height over all, 2 x 3 ft. in horizontal cross-section, and 6000 lb. in weight. It had a framework of cast iron, holding in position the two endless chains of mold blocks, which were made in sections and joined by pins in center alinement. Casting speed would rise to 25 ft. per min. for ⅞-in. brass rod, and mold block temperature was about 450 deg. F. even with some water cooling. In all, about 1000 tons or so of commercial brass rod, mostly 1½-in. rounds of cartridge brass, was cast in this machine. No trouble was experienced with the molds, but the greatest difficulty was experienced in getting the proper flow of molten brass to the point where the mold halves came together. The tip of the silica tube used to transfer the molten brass from the crucible to the pouring point had a tendency to burn off; or, the metal would back up and partially freeze and yank the entire tube off. Elaborate methods of minimizing this tendency were devised, but to the end the accurate control of metal flow was the basic difficulty and was greatly responsible for abandoning the process. The Gar Wood Brass Co. subsequently ceased to exist and the machine was scrapped.

There is to this day some interest in the idea of casting molten metal continuously by means of numerous half-molds linked together in two continuous belts, wherein the molds come together to form a casting chamber, and stay together long enough so the resultant billet can support itself, at which point the belts separate to carry the mold halves back to the casting point. The practice *seems* simple and foolproof. In 1930 the Frenchman, J. Chantraine, with some fanfare prophesied great things for such a method he devised. He spoke confidently of quality of product and economy of operation, and came up with the curious method of cooling the molds with refrigerated air rather than water. But there is no evidence that such a machine was built. Today, the Dortmund-Hoerder Huettenverein, in Germany, is supposed to be using a vertical machine of this type, but with what metal and how successfully is not known. Also, it is believed that Dow Chemical Co. once experimented with a vertical chain machine for magnesium alloys, but if such was the case the idea was abandoned; for this company now employs a downwardly open mold shell of the conventional type.

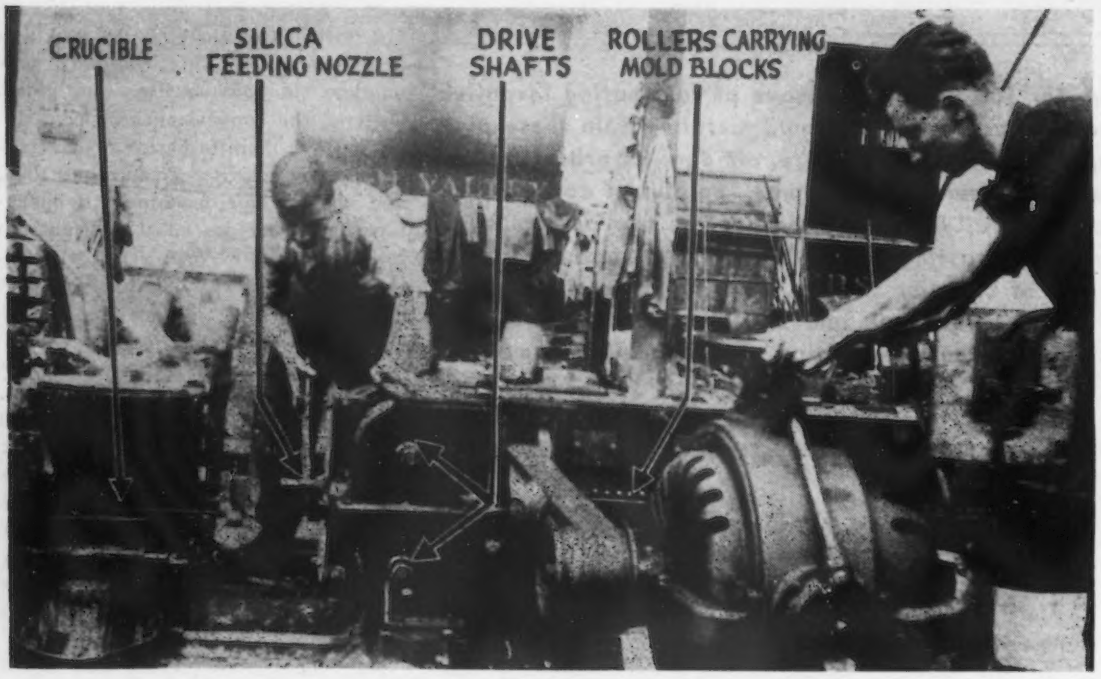
The next definite period of continuous casting activity came around 1940, and the various machines in operation then were described in great detail in THE IRON AGE, April 4, 1940. In the strip-sheet field, C. W. Hazelett had a number of wide casting-rolling mills in experimental operation; and, Merle was doing some work with high-speed film casting of strip. The continuous casting of rods and ingots was showing great promise. A number of Alcoa DC machines were in operation, Poland and Eldred were successfully producing quality copper rod, Williams was experimentally casting steel billets, and Junghans had one billet casting machine in operation on brass in this country.

But, today, the picture has again shifted and expanded. Work on continuous cast sheet or strip has faltered or died, and many of the machines are scrapped. As regards continuously cast ingots and bars, however, the technology has expanded dramatically. In fact, one process not detailed herein has, during the past year or so, continuously cast some thousands of tons of commercial steel billets.

All these shifts and the new work done is brought up to date in the following paragraphs. But, since the details tally up to quite a prolix document, a brief outline of interim changes and current status of thirteen continuous casting may be given as follows:

C. W. Hazelett Process:

The inventor, himself, has lost interest in the continuous casting-rolling of wide strip-sheet. Hazelett's activities today are practically exclusively of a political nature, attempting to interest Washington policy makers in his idea of "incentive taxation" as a means of encouraging industrial enterprise. For this reason the utilization of Hazelett mills has sagged drastically. The International Nickel Co. unit (20 in. wide) and the Scovill Mfg. Co. unit (12 in. wide) both have been scrapped. The Crucible Steel Co. 15-in. mill is still at the Atha works, but inactive. The Aluminum Co. of America 30-in. mill, probably the best ever built by Hazelett, was sold to the Harrison Radiator Division of General Motors Corp., Lockport, N. Y., and a great deal of experimental work is being done on the rolling of brass. Results to date have been encouraging. The Crown Cork & Seal Co. 24-in. mill has been



o o o

● Original horizontal rod-casting machine of Grenville Mellen, 1914. Half-mold blocks are linked together into two continuous chains, which come together to form a casting chamber. Product was brass rod of diameter varying between ⅞ in. and 1½ in. This small unit subsequently was replaced by a larger vertical machine, shown opposite.

o o o

sold to the Winchester Arms plant at New Haven, Conn., which has an exclusive Hazelett license for rolling zinc. This mill currently is inactive. This accounts for the five domestic mills built. Of the three units sold in Japan, nothing is known of the 32-in. mill for zinc which was sold to Mitsui Mining Co., or of the 20-in. copper and brass mill sold to Furukawa. Advices prior to Pearl Harbor indicated, however, that the 16-in. brass mill in the Sumtomo plant was in operation.

The Harrison Radiator work at Lockport suffered considerably because of the war, and despite difficulties of roll deterioration and end-dam cracking, the company is diligently pursuing the problem and believes that results to date promise a successful future for the Hazelett machine. A great deal of excellent brass has been rolled on this unit for the Army, in 6-ton heats, the continuous strip being up to 30-in. wide and 0.012 in. thick. The mill is now working on copper, and likely will handle the quite large copper strip requirements of this plant after the war.

Junghans-Rossi Process:

Six units in commercial operation on brass and light metals. England has one large machine, and Germany has many units in production. Well over 500,000 tons of metal has been cast in this equipment. Described in detail later herein.

J. M. Merle Process:

This high speed method for film casting a thin steel strip onto a moving steel belt or onto a cooled wheel rim is apparently inactive. The three or four machines built for the Allegheny-Ludlum Steel Corp. have all been scrapped. The inventor, now at 9124 S. Laflin St., Chicago, is said to be interested in developing a continuous "cast-drawn" pipe machine for a Brazilian steel company.

Poland-Eldred Process:

The American Smelting & Refining Co. and the Chase Brass & Copper Co. together have purchased all Eldred patents to combine with their own patent structure on the continuous casting of copper rods. One very successful machine in operation at Perth Amboy, N. J., and new units likely to be built. Described in detail later herein.

Alcoa DC Process:

A highly successful ingot casting method, with over 60 units in operation in Aluminum Co. of America plants, and licensed units in operation in the plants of Extruded Metals, Tube- Turns, Bohn Aluminum and Revere Copper & Brass, Inc. This technique described in greater detail herein.

E. R. Williams Process:

Work on this unit for continuously casting steel billets has been shifted to the Republic Steel Corp., Cleveland. Results so far are indefinite. Details described later herein.

N. P. Goss Process:

A method of continuously casting steel billets. Results so far indefinite. Described in detail later herein.

U. S. Steel Corp. Process:

In addition to the interest that one U. S. Steel Corp. subsidiary has in the Goss process, mentioned above, the Corporation also has patented a somewhat unique continuous casting machine, and intends to give it an experimental whirl. The significant feature of the machine is the casting (or extrusion) of a ceramic mold around the liquid metal as it is cast into a billet. This mold is broken away after the billet cools, and reused in part or discarded. Such a mold is being used in an effort to avoid as far as possible the severe heat withdrawal conditions imposed by a short metallic mold. The method may be employed for carbon tool steel analyses.

R. K. Hopkins Process:

Originally used for continuously casting alloy steel onto the side of a carbon steel ingot. This method is a unique procedure which can be considered a continuous casting possibility. Described in greater detail herein.

Dow Process:

One 12-in. machine in operation and two 18-in. machines being built. For casting Dowmetal extrusion rounds. The unit has a single mold chamber believed to resemble the Alcoa DC machine described herein. But, the cast ingot does not drop down on a hydraulic platform—rather, it is pulled down by pinch-rolls and cut to extrusion lengths with a flying saw, just as does Rossi. The Dow casting speed is midway between the Alcoa and the Rossi speeds.

Reynolds Metals Process:

One unit in operation on aluminum alloy ingots. Has a definite physical resemblance to the Alcoa DC machine, but rate and distribution of heat extraction may be different.

Inco Process:

A bar and billet casting machine devised by the International Nickel Co. of Canada and used at the American Metals Co. plant at Carteret, N. J. Inco of Canada has one unit in operation on copper at Copper Cliff, Canada. The Carteret machine continuously casts 3-in. square copper wire bars or 3-in. piercing billets at a rate of about 4000 lb. per hr. The copper is continuously fed from one of two melting furnaces, through a closed runner to the mold chamber. The mold is copper, with many internal passages for coolant. Particularly interesting is that the mold is split in two parts axially, and these parts vibrate very rapidly to overcome friction, the amplitude of the vibration being very small, or less than enough to break the surface tension of the molten metal pool on top. Metallurgical characteristics of the metal are excellent and surface condition of the bar is so good as to not require scalping prior to subsequent manufacturing operations. This machine is very successful in all respects, and additional installations are to be expected.

Soro Process:

The equipment and techniques devised by Junghans, Alcoa, Goss, Poland, Lindner, Eldred, Williams, Hazelett, Merle, Dow, Inco, Reynolds, and a scattering of little known or unknown contemporaries, all fit within the ideological framework of ideas propounded by a long line of 300 or so predecessors reaching back almost 100 years to J. Laing and Henry Bessemer. The past few years, however, have brought forth several unique and unorthodox machines and methods. One of these is best known as Allegheny-Ludlum's Pluramelt process, conceived by R. K. Hopkins of M. W. Kellogg Co.; and the other is the Soro process, hatched by the Swiss inventor Edwin Schuetz, and employed commercially in several countries abroad but still practically unknown in this country.

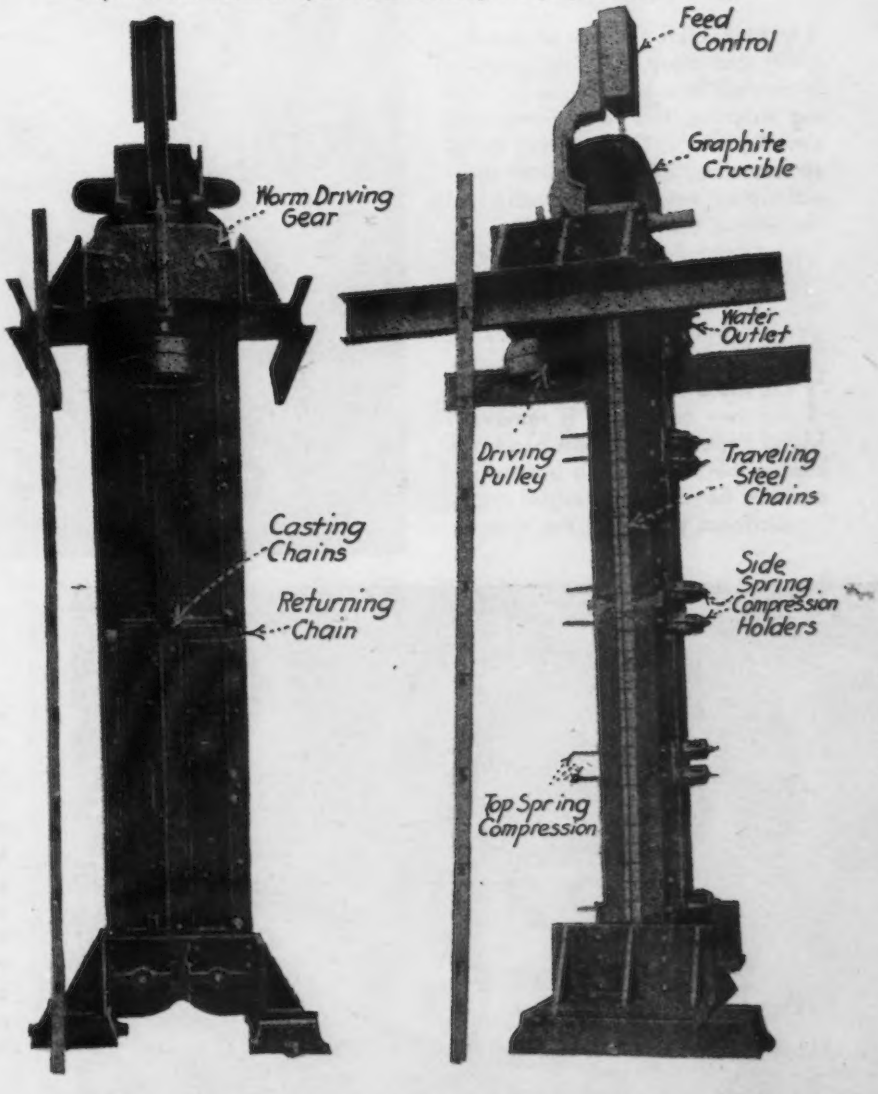
The Soro process certainly cannot be said to fall neatly within the generic boundaries of continuous casting. In fact, it isn't continuous casting—it's centrifugal casting with some specialized technical ramifications. None the less, the end-objective of all continuous casting schemes, that of using a small, comparatively simple and inexpensive piece of equipment to congeal molten metal into either a finished product or a precise and quality product a couple of jumps beyond the semi-finished stage, is fulfilled by the Soro process. And because of this once-removed kinship, the Swiss method can perhaps be fitted within the pattern of continuous casting, and weighed and judged by the same technical and economic considerations applied to the more obviously conventional methods.

While for almost four centuries the poets have belabored the phrase that "necessity is the mother of invention," there is no gainsaying the fact that anger can be an equally effective stimulant to the inventive Muse. Armed with righteous anger and a wad of plant "know how", the inventor of the Soro process showed that it is still possible for the little guy to make the big bad cartel sheath the iron fist and extend not only a velvet glove but a velvet glove with some money nestling therein.

In 1935 Edwin Schuetz was manager of A. G. Oederlin & Co., of Baden, Switzerland, somewhat of a peanut of an industrial enterprise by American standards, but still a profitable producer of a small line of plumbing fixtures and related brass products. That is, it was profitable until the dominating group of Swiss copper fabricators (Swiss Metal Syndicate) in an exquisite demonstration of free enterprise, stabilized rod and bar prices at neat but high level during a period when scrap prices were stabilized at an equally neat but low level. Oederlin & Co. and a few others sweated it out for a while, but after a year or so Herr Scheutz decided to hell with it all, and therewith proceeded to devise the ingenuous Soro process, which converted Oederlin's plant reflow scrap with some pig metal additions into all the bar and rod requirements of the plant.

By 1937 Herr Scheutz had his Soro equipment running full blast. (The tag, "Soro," is what was considered a euphonious mixture of S for Scheutz, O for Oederlin, and RO for ratationsguss or rotational casting.) With a couple of induction furnaces, a battery of three 39-in. diameter

● Improved vertical chain casting machine of Grenville Mellen, which cast brass rod at a 25 ft. per min. speed at Gar Wood, N. J., in 1915. The machine stood 12 ft. high and 2x3 ft. in cross-section. Some thousands of tons of cartridge brass were turned out by this unit. Greatest operational difficulty was proper metal feeding.



Soro Unit

. . . While in no way an orthodox continuous caster, the Swiss-developed Soro process is of the same genus in that it is a compact unit casting molten metal to a finished product. Also, the ability to turn out hot-short metals in long lengths and various cross-sections makes this process one which many a small company could seriously consider.

ABOVE

WHETHER ferrous or non-ferrous alloy, a given quantity is poured into a continuous casting machine, two rings being cast simultaneously. The resulting metal structure has all the excellent characteristics regularly associated with a centrifugal casting.

o o o

RIGHT

THE mold is opened and one of the two cast rings is removed. Metal impurities and sink head are kept within the pouring burr which projects beyond the desired cross-sectional profile of the ring.

o o o

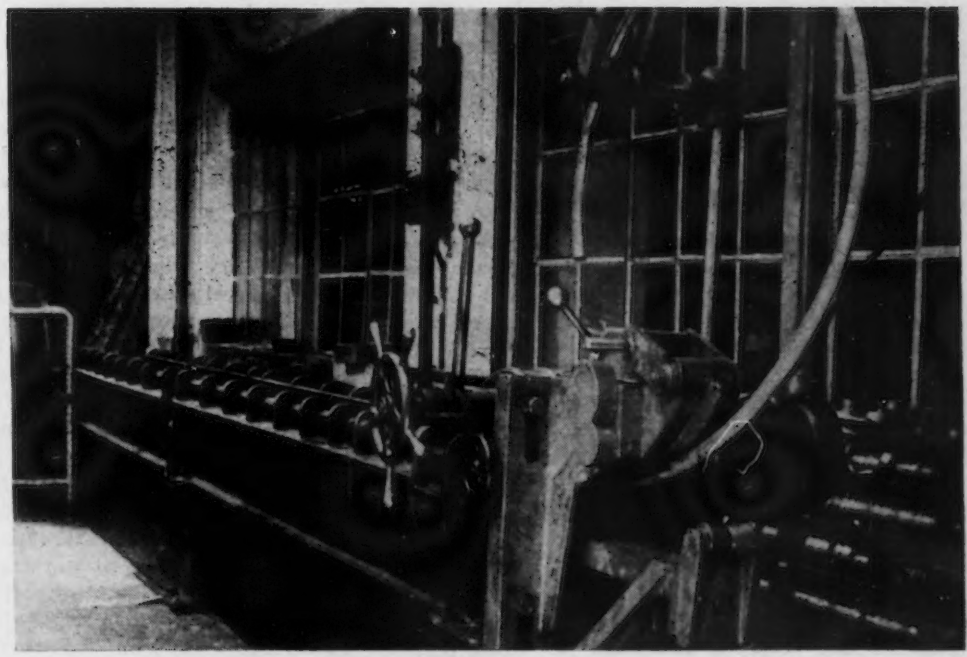
LEFT

THE pouring burr which projects from the inner side of the ring is machined off, leaving the desired profile in sound metal. While these Swiss photos show the original set-up at Baden, newer installations make use of automatic equipment to a much greater extent. Baden capacity is some 1000 tons of finished bars a year, and all equipment from melting furnace to scalping benches are contained within one medium-sized room.

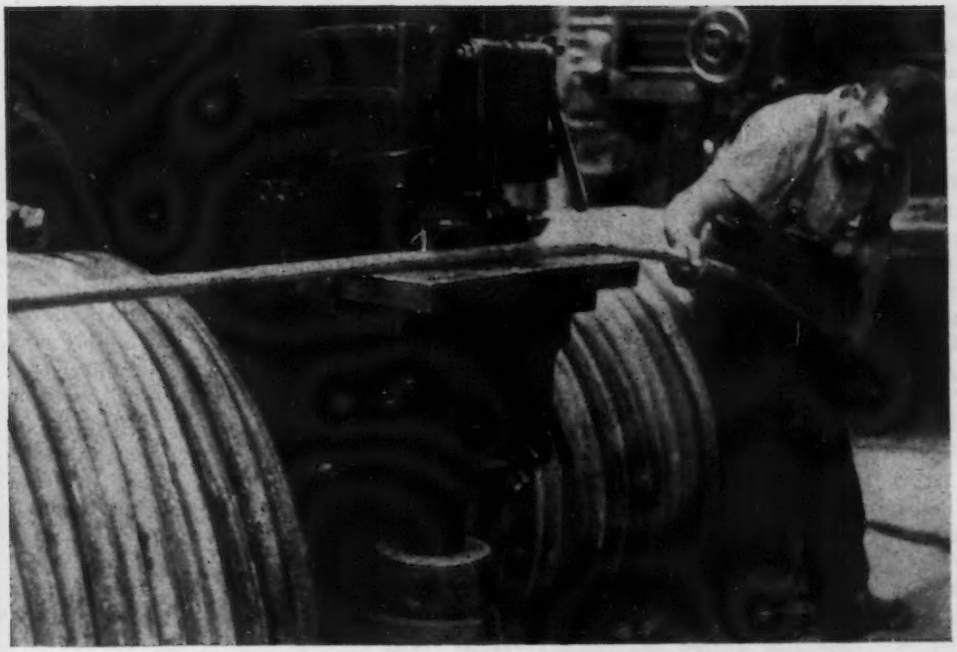
o o o

RIGHT

THE correctly profiled rings are sawed at one point, the two ends being sprung slightly apart in an eccentric press so that one end can be inserted into a straightening die fastened to a draw bench. Note particularly the hammer attachment in front of die which compresses the inner face of the ring, thus preventing fracture of the metal.



o o o



o o o

LEFT

AFTER die straightening, the bar or rod may still be somewhat bent. It is fully straightened with a hammer or press, or more efficiently in a rolled straightener. The rods or bars frequently can immediately be used for upsetting, or for drop or press forgings. In Europe, this equipment is used to produce cartridge brass slugs.

o o o

o o o

RIGHT

MOST frequently the fully straightened bars or profiles are scalped, as shown here, and subsequently drawn to a multitude of smaller sizes for all types of screw-machine work. Any cross-sectional shape without undercut can be cast and drawn to size, thus making available many hitherto unavailable hot-short metals in screw-machine lengths. Production can be stepped up to at least 1000 lb. of metal per machine hour.

centrifugal ring casting machines, an old horizontal lathe, a metal-cutting circular saw, and a draw-bench, all housed within a medium-sized room, Scheutz proceeded to turn out about 1000 tons yearly of Muntz metal and other brass analyses in rods, bars, forging blanks and rolling ingots, and a spotty supplementary output of bronzes, aluminum and magnesium alloys, stainless steels and a couple experimental runs on other alloy steels.

All this had the tendency to make the Swiss Metal Syndicate somewhat fidgety, so after a little formal sparring with Oederlin the Syndicate ended up as exclusive licensees of the Soro process in Switzerland (Oederlin excepted) on a rather satisfactory yearly royalty basis. While the syndicate has yet to build or operate a Soro unit, Oederlin turned to other countries and promptly proceeded to make a deal with the very large Government-owned armament plant of Zbrojovka in what was then still Czechoslovakia, which built a greatly improved unit for turning out bronzes and cartridge-brass slugs. Germany's largest copper and brass producer, Mansfelder Huettenwerke, at Hettstedt, likewise negotiated a license primarily on cartridge-brass production; while a smaller German firm, F. A. Lange, at Aue-Auerhammer, signed up primarily for aluminum rolling ingots. One of France's largest screw machine fabricators, E. Dubied, at Pontarlier, likewise, was soon licensed, as also was the large Italian outfit of Bombrini & Parodi, the wreckage of whose plant at Rome it is hoped that the Allied Fifty Army will soon be sorting out. A Polish government arsenal was licensed, as has also been the case in Sweden and Brazil. And Langley Alloys, at Slough near London, England, secured a license and got drawings out of Switzerland in time to get a machine built, but have been unable to get technological help to push the unit to capacity operation. All these activities have brought to Oederlin coffers some $750,000 in licensing fees, not an insignificant total for a company with but several hundred employees.

In the United States all Soro rights are owned by American . Abrasive Metals Co., at Irvington, N. J. (American patent 2,175,574, applied for in 1937 and issued in 1939), the rights being exploited with the assistance of Emri I. Valyi, vice-president of Sam Tour & Co., Inc., 65 Pine St., New York. One ring-casting centrifugal machine at Irvington is quite large, 62 in. in diameter, and for the past year or so has turned out quantities of 88-10-2 and 85-5-5-5 bronze rings, weighing approximately 500 lb., replacing sand castings for ordnance work. Currently, equipment is being set up for the experimental casting and drawing of bars and rods in a great variety of non-ferrous and ferrous alloys.

A series of pictures showing the sequence of operations of the original and rather crude Soro installation at Baden is shown herein on pages 52 and 53. Measured quantities of metal, preferably melted and refined in either an induction or arc furnace, are fed to a centrifugal casting machine. This machine is made up of readily demountable iron molds, double-faced for casting two metal rings simultaneously. The diameter of the cast ring may be about anything that desire dictates, varying from the 39-in. size at Baden to the 62-in. diameter at Irvington, or even larger. Cross-section of the ring may be a fraction of an inch or several or more inches, and may be round or any complex profile just so long as no undercuts are involved. The mold aperture is such as to give the cross-section desired as well as a pouring burr on the internal diameter wherein is concentrated the sinkhead or pipe and all chemical segregates associated therewith.

A cast is made, the mold is broken apart, rings removed, molds cleaned and a wash applied, and molds reassembled for another cast, the complete cycle requiring a comparatively short time interval. In fact, the machine can be rigged to cast every minute or so. A battery of, say, four machines is capable of casting some 2 tons of 3-in. copper alloy bar per hour. The rings then go to a horizontal lathe, which if equipped with automatic chucks and a form tool can readily remove the internal bead at a couple of swipes, leaving a correctly profiled annular cast of sound metal.

Next step in the operation is cutting the ring at one point with a small metal saw, then using an eccentric press to spread the two ends sufficiently apart to permit one end to be entered into straightening device attached to a draw-bench. This first draw-bench manipulation involves no reduction, the primary objective being to stretch the ring out approximately straight. The crux of the Soro operation is this first approximate straightening and the American patent is concerned just about exclusively with means for producing a compression and stretching of the metal adjacent to the inner face of the cast ring during the straightening, in order to obviate cracking or fracture. This compression may be carried out by a pair of pressure rollers, or more commonly (as shown in the illustration) by a hammer arrangement accentuated by compressed air, an electric motor or in some other mechanical manner, which hammer is located just ahead of the matrix or drawing ring of the draw-bench.

When straightened rods of accurate profile are desired, one end of the cut ring is placed on the device located at one end of the drawing bench. On the column of this bench are mounted rollers to guide the ring and produce slow opening thereof. The ring is so placed on the bench that its inner side is turned, for example, upwardly. One end of the ring is passed through the matrix or drawing ring and engaged by the jaw of the drawing carriage. As this pulls, a compressed air hammer located in front of the matrix rapidly strikes the ring's inner face and compresses and stretches the metal at this point.

The rod or bar is next hand-straightened under a press or trip-hammer although hand-straightening represents some penny-pinching on the part of Oederlin, and a more modern unit naturally would employ a roller straightener. At this point much of the brass rod or bar can be cut into forging blanks and sent immediately to the forge shop for fabrication, or to machining equipment for turning into final end-products. Large quantities, however, are scalped and progressively drawn to smaller sizes for a multitude of screw-machine or upsetting operations.

The Soro process, of course, brings to mind some prior art. One case readily cited is the well-known practice employed for years by the Rotary Electric Steel Co., of Detroit, whose practice is one of centrifugally casting large steel rings of ingot or billet-size cross-section. These are cut into segments and rolled or otherwise shaped to final end-products. Rotary, however, apparently has been concerned primarily with large breakdowns and has not exploited the continuous casting of small cross-sectional, practically finished bar and rod end-products, Elsewhere, scattered throughout all the basic ideas worked and re-worked with infinite ramifications and alterations in patent literature, other men have explored the art of centrifugal casting as a means of approximating continuous casting objectives. But of these ideas none resembles the Soro method.

In 1928, K. Suresch (deutsches Reichspatent 498,045) proposed a centrifugal casting unit that would spin two continuous wires. While this

machine was on paper designed for ferrous metals, it never got beyond the patent drawing stage. Years prior to that date (1907) somewhat the same end befell similar machines by F. W. Winner, Director of the Government (German) Steel Works (deutsches Reichspatents 215,352 and 215,447; American patent 950,884); and by N. Crane (American patent 1,444,953). J. M. Merle (American patents 2,129,702; 2,129,703) in 1934 proposed what he calls a film casting process, wherein metal with the latent heat substantially removed is projecting from a revolving disk in the form of a mass of separate particles (which may accumulate in a mold cavity), and subjecting each particle to a forming force while it exists at a temperature slightly below the freezing point and is plastic. Here again, it is doubtful whether such a machine has ever approached commercial operation. Other than these examples, centrifugal force has been pretty well ignored by the multitude of men who have throughout the decades been fascinated by continuous casting.

Merle's patents also deals with flowing a film of metal onto a rapidly moving metal belt, or rim of a wheel, to secure a continuously cast strip. As already mentioned, four experimental machines of this type were built and tried at the Allegheny-Ludlum Steel Co. plant Brackenridge, Pa. However, results were discouraging and the machines were subsequently scrapped.

● R. K. Hopkins method of continuously casting alloy steel against the face of a carbon steel billet, as used in the plant of Allegheny-Ludlum Steel Corp. This method is entirely different from customary continuous casting procedures, but could possibly show encouraging results in the continuous casting of steel, particularly the high-alloy types.

Being a comparative newcomer on the industrial scene the Soro process is still pretty much of an unknown quantity as regards its ultimate position among metal-working methods. It would seem, however, that if it can be an effective tool in the hands of the small entrepreneur in Switzerland, it also has possibilities of being of use to the small or intermediate manufacturer in the United States. The bulk of production so far by the Soro method has been in non-ferrous alloys, particularly in brasses and bronzes, and in the light metals. Where a plant operation involves a great amount of screw machine work, or other manufacturing producing large volumes of circulating scrap, the Soro equipment could be an adjunct making the plant to some degree self-sufficient. Also, equipment of the Soro type could possibly find a place in remote sections exploiting local scrap supplies while satisfying sectional small lot steel requirements.

Particularly in the ferrous field, the Soro bar is very much an unknown quantity. Being intermittent in operation and suffering as it does from cut in metal yield because of bar-end loss and pouring burr loss, the method in no way could be considered a competitor of the large integrated mill, mass-producing standard sizes and analyses with continuous rod or bar mills which disgorge at a 2000 ft. per min. clip. But normal steel business involves large numbers of small orders for special sizes and analyses, and here the Soro method could perhaps snuggle into a cozy niche. Similarly, certain remote areas with moderate demand and a steady flow of return scrap could perhaps support a Soro unit whereas an integrated mill would be impracticable.

One possibility the Soro equipment could perhaps exploit with belligerence would be the supplying of hot-short alloys in bar and rod form, which are not readily available now. For instance, the zinc-base Zamak alloys (95 Zn, balance Al, Cu/Mg) heretofore die cast, could be furnished as screw stock and thus compete with various brass analyses. The same applies to the 88-10-2 variety of bronzes and other high strength "foundry" alloys. Certain of the light metals, particularly the secondary metals in wrought forms could be conveniently handled with this equipment, and such is common practice in Switzerland. The same applies to certain bearing metal mixtures which usually are cast or machined to shape, but could obviously be more conveniently handled in a drawn form.

As regards ferrous metals, there are a great variety of high-alloy steel analyses that certainly could plumb attractive and expanding consumer applications if more readily or cheaply available in small lots and in a variety of accurate, drawn, intricate profiles. But, this ferrous picture a year from now can be weighed more judiciously, as so far the sketchy and inconclusive experimentation has been more imaginative than practical. Some ferrous analyses would certainly require heat treatment prior to the first cold straightening operation or subsequent drawings. But, in general, if the material should have an elonga-

Alcoa D. C. Unit

. . . First photographs of the Aluminum Co. of America's D. C. (direct casting) machine, which casts set lengths of billets on a recurrent cycle. Developed and perfected over the past 10 years by Alcoa engineers, this machine turns out the company's entire requirements of aluminum and magnesium extrusion rounds and sheet ingots in all analyses with the exception of 2S and 3S aluminum. There are now more than 60 D. C. machines in operation, all in Alcoa plants, with the exception of four licensed by other companies. The machine shown here in detail is the comparatively new unit in the plant of Extruded Metals Corp., Grand Rapids, Mich.

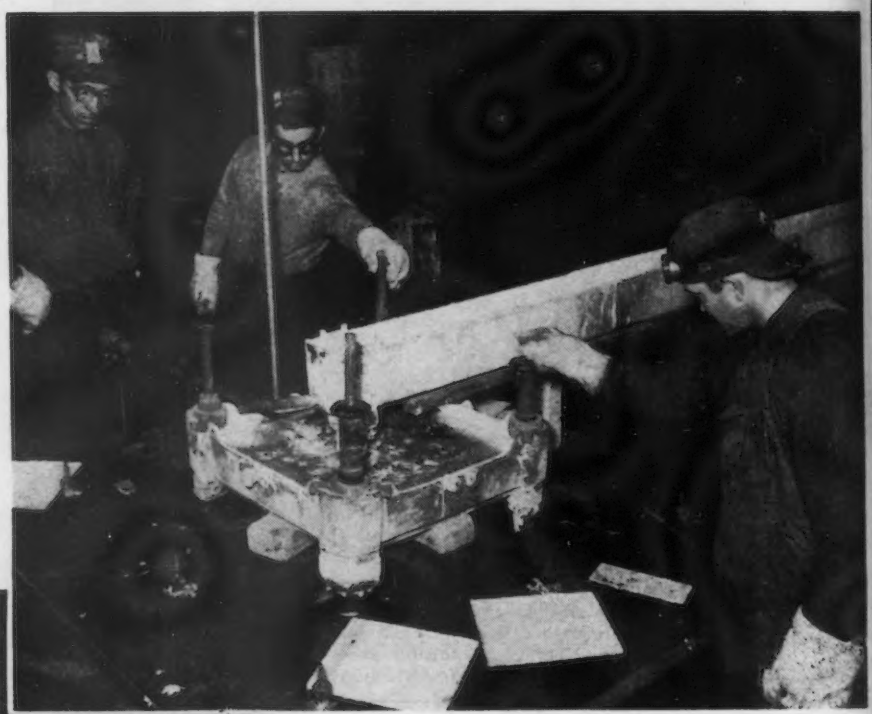
ABOVE

THE four water-cooled molds prepared for a cast. The molds are 10 in. deep, are made of 53S aluminum alloy. The mold coating is grease, a thread of asbestos seals the crack between the mold and the hydraulic platform, the latter dropping away as the cast progresses.

o o o

BELOW

A RUNNER carries the aluminum or magnesium from the furnace to the distributor pan. Alloy 17S, which is being cast here, has a furnace temperature of 1375 deg. to 1385 deg. F., the metal temperature in the pan varying between 1270 deg. and 1325 deg. F.



ABOVE

OVER the four molds is set a distributor pan, made of high grade cast iron and carrying four cast iron adjustable feeding nozzles. Aluminum alloy is delivered from the furnace, via the runner, to build up a 5-in. head in the pan, after which the individually controlled nozzles are opened and adjusted to feed metal into the molds at a proper speed. One "drop" casts the output of one melting furnace, after which the entire operation is repeated on tapping another furnace.

o o o

RIGHT

THE hydraulic platform has started to drop away, carrying the solid 11-in. ingots with it at the rate of 3 in. per min. Note the distributor pan at the top. Some 7 to 25 per cent of the heat of fusion is extracted through the mold, the remaining heat being removed from the embryo ingot by means of water spraying onto the surface, as shown here.

o o o

The balance of metal temperature, pouring speed and the intricate nuances of heat extraction determine the grain disposition, orientation and homogeneity.

o o o

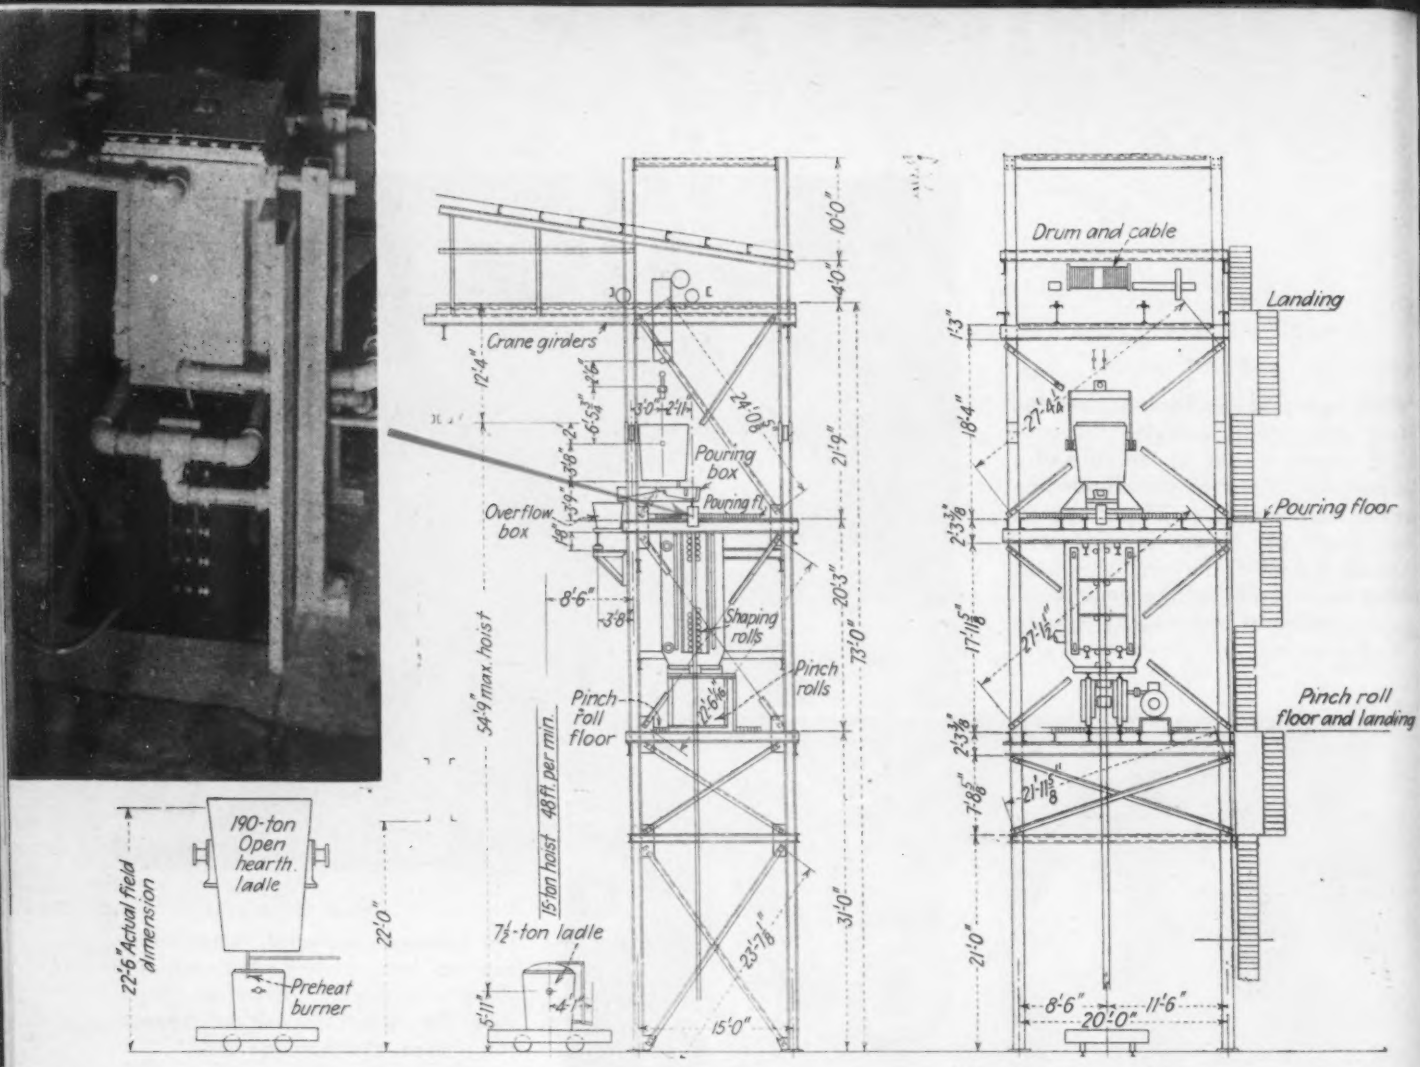
ABOVE

THE platform drops down until the billets are about 10 ft. long, the time interval being some 40 to 50 min. The unit easily makes five drops each 8 hr., with some 4500 lb. of metal cast per drop. Here the cast is completed, distributor pan and mold unit have been lifted off, and the hydraulic platform partially elevated so the casts can be lassoed with a crane sling.

o o o

RIGHT

THE casting pit as seen from the crane. Two casts have been lifted out, and the remaining two are being removed. Each of these 10 ft. x 11-in. ingots go to a cold sawing machine, for cutting into billet lengths suitable for subsequent extrusion. The only metal loss is the saw chips, which are routed back into the furnace for re-melting. Casting of sheet ingots and blooming mill squares follow the same cycle.



● E. R. Williams machine, used for experimental continuous casting of steel at the Republic Corrigan-McKinney plant. The original Williams mold arrangement (picture insert) has so far been used, but the impressive Republic structure permits casting of 50 ft. lengths, which can be cut into billet sizes with an oxy-acetylene follower lance. About 40 casts have been carried out on this equipment.

tion factor of 15 to 20 per cent, it could be successfully cold-straightened in the as-cast condition. Many of the free cutting high-sulphur steels, particularly the leaded varieties that undoubtedly will enjoy great postwar popularity, may well lend themselves readily to Soro casting into bar form requiring few additional manufacturing operations prior to being chewed up by screw machines. The same applies to a number of tool steels compositions, which could perhaps enjoy the advantages of soundness, lack of ingotism and segregation, and availability in lengths and sizes heretofore unobtainable without a long series of rolling or forging operations. Even centrifugally cast tool bits, generally a high quality product, sometimes show segregation, which factor would not be a factor in the small centrifugally cast Soro section.

Pluramelt (Hopkins) Process:

The Pluramelt process used by the Allegheny-Ludlum Steel Corp. was originally developed to face carbon steel ingots with stainless, tool or other alloy steels. Either slabs or ingots of carbon steel are fastened into the Pluramelt machine and any desired thickness of alloy steel is continually built up on one or more surfaces. This procedure, which has been steadily employed in the production of carbon steel faced with stainless steel, and also carbon steel faced with armor steel, has been described in detail in THE IRON AGE issue of March 6, 1941, and is covered by Hopkins equipment and process patents Nos. 2,107,943 2,151,914; 2,151,915; 2,174,-175; 2,191,469; 2,191,470; 2,191,471.

Inasmuch as the Hopkins process is essentially a continual building-up of a slab of metal, and since this building-up can take place without interruption in a metal or ceramic mold rather than alongside a carbon steel ingot, it also can be considered a running-mate with all the other machines and procedures detailed herein.

In the photograph reproduced on page 55 herein, the unit is shown in operation while facing a carbon steel slab with stainless steel. But the functioning of the machine would be essentially the same in a metal mold. What makes this practice so very unique is that molten metal is not brought to the machine from a conventional refining unit, but rather is produced right in the mold by what is essentially a precision electric arc furnace, continuously fed with exact pre-determined quantities of raw materials which melt to form an alloy steel under a carefully controlled refining and protective slag. A moderate-sized machine can easily melt, refine and cast even the most complex of alloys at a rate of over one ton per hour, and this pace can be stepped up considerably without much difficulty.

The working head of the Hopkins machine operates under a slag blanket. The head is made up of a number of carbon steel tubes which also function as electrodes, the result being a multiple arc furnace. Down these tubes there is a continuous and precise feeding of steel constituents. The feeding equipment is made up of a number of metering machines, all controllable from a central operating panel, each meter being connected with a hopper containing a particular raw material. One hopper, for instance, may contain powdered ferrochromium; another, powdered ferrosilicon; another, ferromanganese; another, ferrocolumbium; another,

ferrophosphorus, etc. Iron powder also can be fed into the working head, to supply the iron constituent of the alloy.

There is practically no limit as regards the complexity of alloy constituents that can be metered into the system at one time, although no little skill is obviously required in determining metering rates, as each of the ferroalloys carry fractions of various elements into the system, the carbon steel contributes fractions of various elements, and each ferroalloy has a different rate of recovery. Slag constituents are usually fed by hand as required. Electrical energy naturally varies with the alloy being cast and the speed of the casting.

Steel made in this manner is very uniform. Furthermore, many analyses can be so produced that are difficult or well-nigh impossible to produce by conventional refining and metal-working methods. And the unit can, in the confines of one small room, convert raw materials to a semi-finished product that can go directly to a rod or sheet mill, or to the drawing bench. Here again, because of compactness and small capital investment a means is offered for remote operation on a scrap economy, or operation on complex alloys or short-run orders as a supplement to mass-production equipment handling bulk orders of standard analyses or sizes.

Alcoa (DC) Process:

Based solely on the criterion of tonnage of commercial metal produced, the Alcoa DC (direct casting) equipment is by far the most successful in operation in this country and has long been the object of a lively multilateral interest. Every ounce of aluminum and magnesium extrusion rounds and sheet ingots produced by the Aluminum Co. of America, with the exception of the simple 2S and 3S analyses, pass through this type of continuous casting unit. And, the only reason the comparatively pure metals 2S and 3S are still cast in tilt molds rather than in the DC machine, is that the excellent metallurgical features of DC casting is of little moment in the casting of pure metal.

Large tonnages of aluminum and magnesium similarly are handled in Alcoa-licensed machines in the plants of Extruded Metals, Revere, Bohn and Tube-Turns. Thus, it is apparent that the bulk of the country's light metals has passed from conventional casting equipment into continuous casting machines during the past several years. This constitutes quite a radical change, indeed, in production technique in a very important segment of the metal working industry. And, surprisingly enough, all this has taken place with nary a trace of a panegyric.

A sequence of photographs showing the passing of metal through the DC unit is shown on pages 56 and 57. In the particular instance recorded, the machine is casting 11-in. round billets in the 17S analysis, in lengths approximately 10 ft. long which are subsequently cold-sawed into extrusion length billets. This particular DC unit is producing at a rate of about 25,000 lb. of metal every 8-hr. turn, but this output can vary considerably depending on ingot size, number of molds being poured simultaneously, and analysis of metal being poured.

In the case of the machine shown, the 17S alloy has a furnace temperature of 1375 deg. to 1385 deg. F., and passes down a runner to a cast-iron distributor pan, equipped with four cast iron nozzles, individually controllable, each of which feeds a casting chamber. Metal temperature in the pan is, say, 1270 deg. to 1325 deg. F., and a metal head of about 5 in. is maintained in the pan.

The molds are simple aluminum (53S) tube sections 10 in. in length, set into a steel plate framework. On occasion 2S alloy is used to make the molds, and this analysis stands up to heat erosion better but will not take the bumps and tears of 52S. Copper and brass molds likewise have been used, but here again mold performance, particularly as regards tearing, does not equal the 52S aluminum analysis. About one-quarter of the heat of fusion is extracted through the mold wall, which is cooled by water sprays or jets. The remaining heat is extracted by multiple water sprays directed around the Periphery of the ingot shell.

A hydraulic platform underneath the molds drops down at a speed of about 3 in. per min. carrying the four casts with it. The entire cast (or drop) takes about 40 or 50 min. at which time the ingots are some 10 ft. or more in length, depending on the size of the particular furnace heat. At the end of the cast, the distributer pan is removed, the platform is lifted sufficiently to loop crane slings around the ingots and lift them from the pit. Subsequently the platform is again lifted to floor level, the distributer pan again set in place, and everything readied for another cast. Of course, if so desired, the platform arrangement could be replaced by pinch rolls and automatic cut-off saws in much the same manner as the Junghans (Rossi) arrangement. But since the speed of casting of each individual ingot is far lower than for the Rossi machine, such automatic cut-off equipment would be considered more of an ostentation than a practical operational adjunct.

Sometimes the molds are greased with a solid lubricant (not liquid), but this practice varies considerably from plant to plant. Of all the simple and complex aluminum alloys cast, the 24S analysis is the most critical to cast in the DC unit (which is also the case in the Junghans machine). Aud the avoidance if internal cracking and coarse constituent distribution are tied sensitively to the rate of cooling, speed of drop, and location of cooling sprays. One of the important problems in this machine, as in the case of all light alloy casting procedures is that of securing and maintaining of clean metal. But even more important, particularly when dealing with the more complex alloys, is the securing of the metallurgical structure desired. Here is where the method and degree of cooling, speed of pouring, and subtle control of all the other variables come into play to determine homogeneity, fineness and orientation of grain structure. All these factors rule whether one casting process may be superior to another. It is also equally true that the fund of practical experience in the hands of one group of technicians may be of considerably more importance in the final successful functioning of a particular machine, than, say, the design of the unit itself.

It is the backlog of experience and "know how" that bolsters Alcoa's role in the technology of continuous casting. In fact, Alcoa's patent (W. T. Ennor, No. 2,301,027, issued Nov. 3, 1942) covers not machine construction but explores all the delicate nuances of temperature gradients and operational technique.

Well over 60 DC units are in continuous commercial operation in this country. The mold sizes vary from 8 in. to 16 in. in diameter for round extrusion ingots; sheet ingots vary in cross section from 6 x 22 in. to 12 x 48 in.; and squares for blooming mill work vary from 8 x 8 in. to 18 x 20 in. in cross-section. Some of the older units cast in 90 in. lengths, whereas the newer units cast in lengths in the neighborhood of 140 in. These sizes apply for both aluminum and magnesium, although magnesium sheet ingot cross-sections are usually of the smaller size mentioned above. In magnesium, emphasis on round castings for extrusion is expanding considerably with the growing tendency to pre-extrude all strip billets, a practice for years common with I. G. Farbenindustrie in Germany.

Several years ago Alcoa experi-

mented extensively with screw-type pumps immersed in the magnesium furnace for pumping the metal over to the DC casting unit. The Germans have used this technique for some years, but Alcoa found that pump maintenance was so troublesome and costly that this feeding practice was temporarily discarded. However, in light of development of better pump materials and designs, the question of employing submerged pumps is now being re-examined. The author understands that Dow Chemical Co. likewise is experimenting with a submerged pump system for transferring magnesium from the furnace to continuous casting equipment.

As already mentioned, Extruded Metals Corp., Bohn Aluminum Corp. and Tube-Turns, Inc., have Alcoa licenses and machines in commercial operation on aluminum. Revere Copper & Brass, Inc., has a DC machine and a license for both aluminum and magnesium, and it is understood that this company has intention of becoming the largest magnesium sheet producer in the country. As regards Reynolds Metals Co., its continuous casting equipment has marked physical resemblance to the Alcoa DC equipment, but operational variations likely exist which are not known to this writer.

The fact that considerable heat is extracted from the molten metal in the DC process in a downward direction through the semi-solid metal, has already been mentioned. This, of course, is one reason for the slower rate of operation as compared with the Junghans and Williams types of machines, wherein the bulk of the heat is rapidly extracted laterally. In this respect, the Alcoa process resembles the Eldred and Poland (A.S.&R.) technique, although the latter two methods particularly accentuate longitudinal heat extraction by employing heat-resisting graphite molds rather than heat-conducting metal molds. Whether essentially longitudinal or lateral heat extraction, or some combination of the two, the final result is an infinite number of possibilities as regards casting speed, and orientation size and uniformity of crystal disposition in the cast ingot.

Any possible interference between the Alcoa process and the Eldred patents was laid to rest several years ago, when the Aluminum Co. of America and Eldred's licensing company, the Continuous Casting Corp., signed an agreement. This was some time prior to the acquisition of all Eldred patents by the American Smelting & Refining Co. That A.S.&R., in association with Chase Brass & Copper Co., secured the B. E. Eldred patents 1,868,099; 2,048,733; 2,048,734; 2,055,980; 2,135,465 to bolster and complement their patent structure (i.e., Poland-Lindner 2,136,394; Poland 2,131,070; Lindner 2,157,550; Betterton and Poland 2,195,809, seems like a desirable move inasmuch as this writer in the 1940 article on continuous casting pointed out the marked similarity of equipment, technique and metallurgical characteristics of metal produced.

Junghans (Rossi) Process:

As the writer described in great detail, in the April 4, 1940 issue of THE IRON AGE, the Junghans (Rossi) method of continuous casting is a highly orthodox unit in which casting of large billets may continue uninterrupted for days at a time, the metal being cut into billet lengths by means of a flying saw while in motion. In 1940 only one American company, the Scovill Mfg. Co., had a Junghans machine in operation, and it had already cast some 60,000,000 pounds of commercial brass, mostly in 7⅞-in. round sizes. This figure is currently approaching 400,000,000 lb.

In April, 1940, James Booth, Ltd., Birmingham, England, had just initiated production in a larger Junghans machine, casting aluminum alloys, mostly extrusion rounds up to 16 in. in diameter. Since 1938 or so, Siegfried Junghans had a unit working continuously at the plant of I. G. Farben Aktiengesellschaft, Bitterfeld, Germany, for aluminum alloy ingots in rounds up to 20 in. in diameter, and rectangular sheet ingots of approximately equivalent cross-section. At Ulm, Germany, Wieland A.G. had two units in operation, one an aluminum-brass machine primarily for 8-in. extrusion rounds for condenser tubing, the other for 24x4-in. cartridge alloy sheet ingot. Wintershall A.G., Kassel, Germany, had a machine casting magnesium alloys, and Junghans himself had a semi-commercial and developmental unit at Stuttgart.

Although most of the German plants mentioned have been bombed repeatedly over the past six months, some information coming out of the country via Switzerland since the war began leads to the belief that there has been great expansion in Junghans installations all over Germany, designed primarily to supply light-metal extrusion rounds for the aircraft industry, and cartridge brass rolling ingots for the ordnance plants. Also, some information so far unconfirmed, has it that some non-ferrous composite castings have been made; also that certain alloy steels are being handled in Junghans units, and even that some ferrous metals have been so turned out in tube form.

Since 1940, a number of larger and better engineered Junghans-Rossi machines have been built in the United States, for use primarily in the brass industry, whereas it has already been demonstrated that the Alcoa D.C. process dominates the light-metal field as the natural result of Aluminum Co. of America's long supremacy in such production. In addition to the original Scovill unit working on extrusion rounds up to a maximum 10 in. in diameter, the same company has since 1940 installed a larger machine primarily for brass sheet slabs up to a maximum width of 24 in. A neighboring company, the Bridgeport Brass Co., has installed three Junghans-Rossi machines, one for slabs up to 30 in. wide, and two for extrusion rounds up to 10 in. in diameter. The very energetic Extruded Metals Corp. at Grand Rapids, Mich., over a year ago initiated production in a unit for aluminum rounds up to 14 in. in diameter, and under the direction of the president, John Barrett, has conducted some very informative and valuable basic research on the continuous casting of light metals.

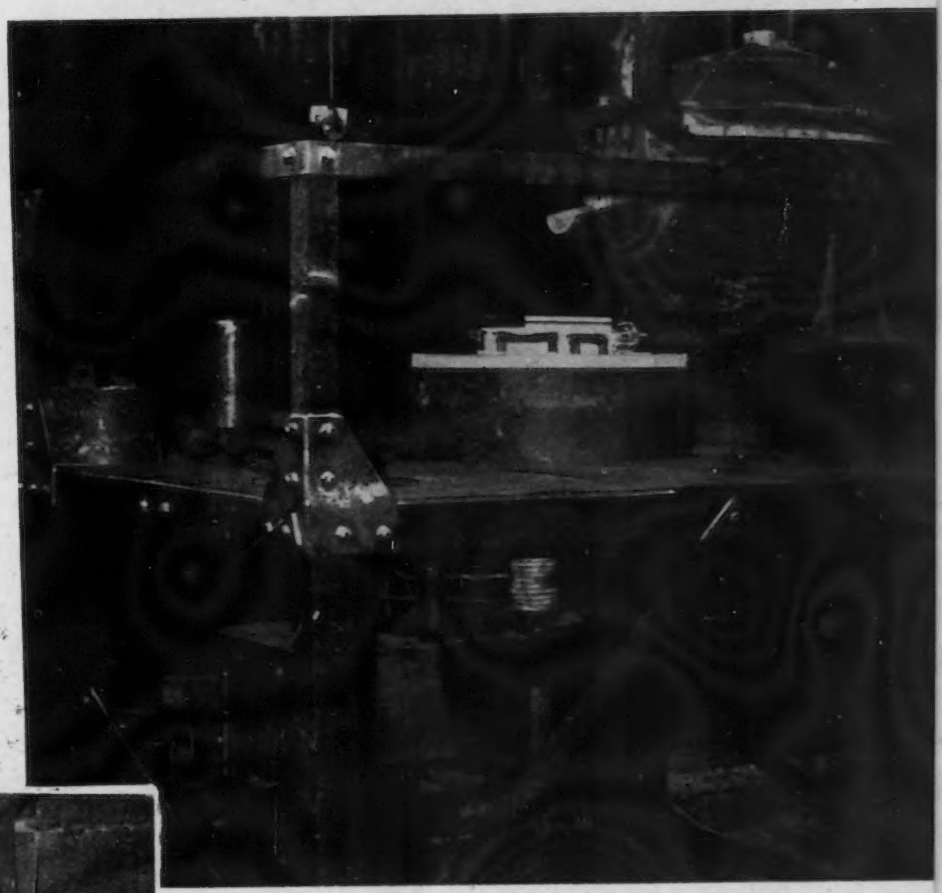
The sequence of photographs shown on pages 62 and 63 deal with the Extruded Metals Corp. unit working on aluminum alloy extrusion rounds. Delivery speed of this machine is anywhere from 5 to 20 in. per min., equivalent to some 100,000 or so pounds of aluminum alloy billets per 8-hr. turn. This is about four times the output of the Alcoa DC unit previously described herein, which is in operation at the Extruded Metals plant adjacent to the Junghans equipment. This comparison of the two methods, however, is rather meaningless, as the two machines vary considerably in size and capital expenditure involved, and each can handle a great variety of ingot sizes and analyses of metal, all of which has a definite bearing on the individual rate of output. But, since the Junghans-Rossi machine delivers a particular analysis of metal in a particular size at a considerably faster rate than an Alcoa DC mold, it is obvious that cooling of the molten metal is taking place much more rapidly.

As new Junghans-Rossi machines are developed, the casting speed is slowly rising. Scovill is now casting 8-in. diameter brass billets at the rate of 16,000 lb. per hr., or about 360,000 lb. per day, and this rate is maintained with deadly constancy for days

Bethlehem Unit

. . . First pictures of the 1941 experiments by Bethlehem Steel Co. in continuously casting 4-in. steel rounds in a small test unit (right) at the Lebanon, Pa., plant. This exploratory investigation is typical of others quietly conducted by various producers.

SURFACE condition of the continuously cast steel was poor (above), including fissures, break-throughs and laps. Thermal cracks were particularly severe for analyses above 0.30 carbon. Optimum speed for this experimental lay-out (right) was 10 ft. per min.

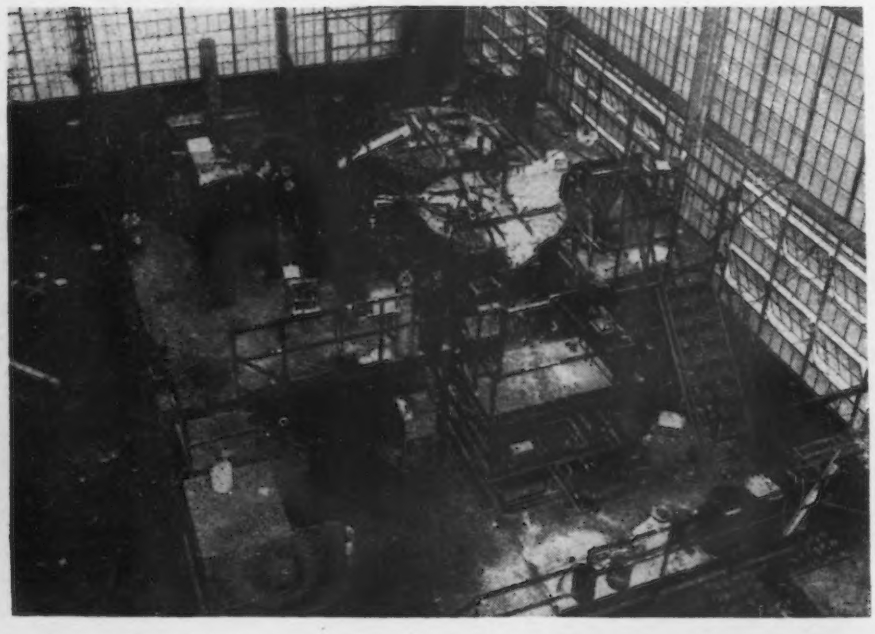


o o o

A 300-LB. arc furnace delivered steel to a reservoir (left), wherein temperature was maintained by Globar units. Pinch rolls pulled the cast steel from the mold (right), the latter being of copper and water-cooled by means of copper tubing fastened to the outside wall. Thermal deterioration of the mold was no problem.

o o o

Junghans (Rossi) Unit



. . . First views of the 14-in. Junghans machine at Extruded Metals Defense Corp., Grand Rapids, Mich., sometimes known as the Rossi machine after the owner of world (excluding Germany) patent rights. This is the largest (and newest) machine for rounds in the U. S., although a 16-in. unit has long been in operation in England. Junghans' continuous casting machine is orthodox in that with an aluminum or magnesium alloy cast once started it may progress for days without interruption, the solid ingot being automatically cut into billet lengths by a flying (sic) saw.

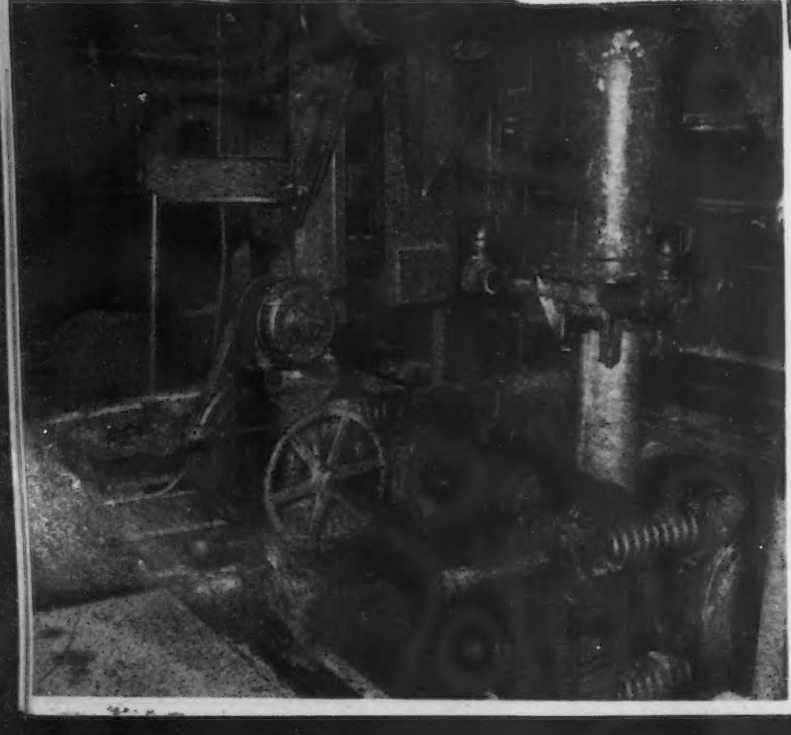
ABOVE

TOP view of the Rossi machine, showing the two electric holding furnaces to the rear, with electrically heated feeding tubes leading to the oscillating casting mold just in front of the control panel.

° ° °

RIGHT

A LADLE of molten aluminum alloy has come via crane from the melting furnace and placed on the tilting platform in the background, to fill one holding furnace while metal from the other furnace is forced by gas pressure through the feeding tube into the mold chamber. The proud gentleman in the back, with hat, is Irving Rossi.



° ° °

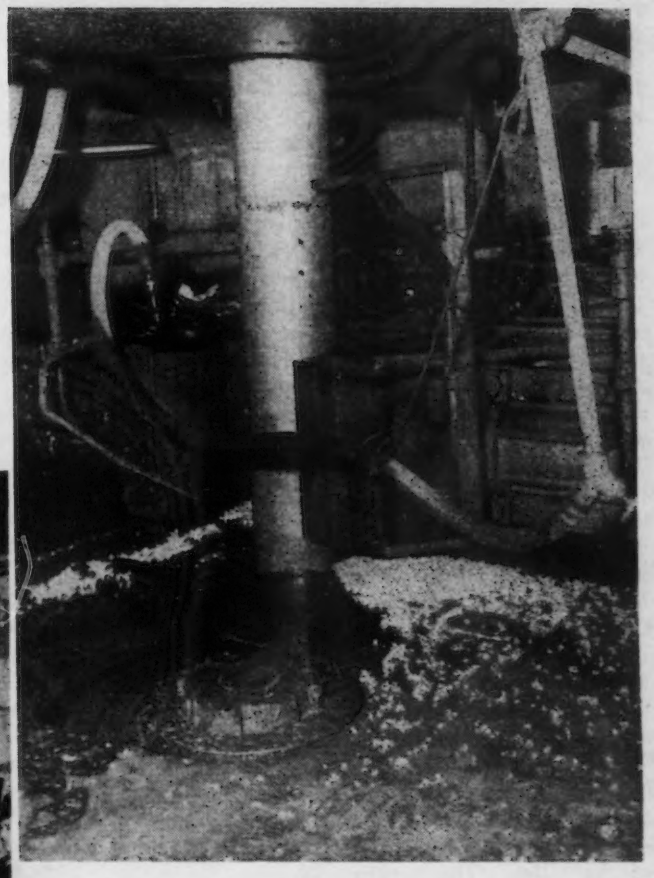
LEFT

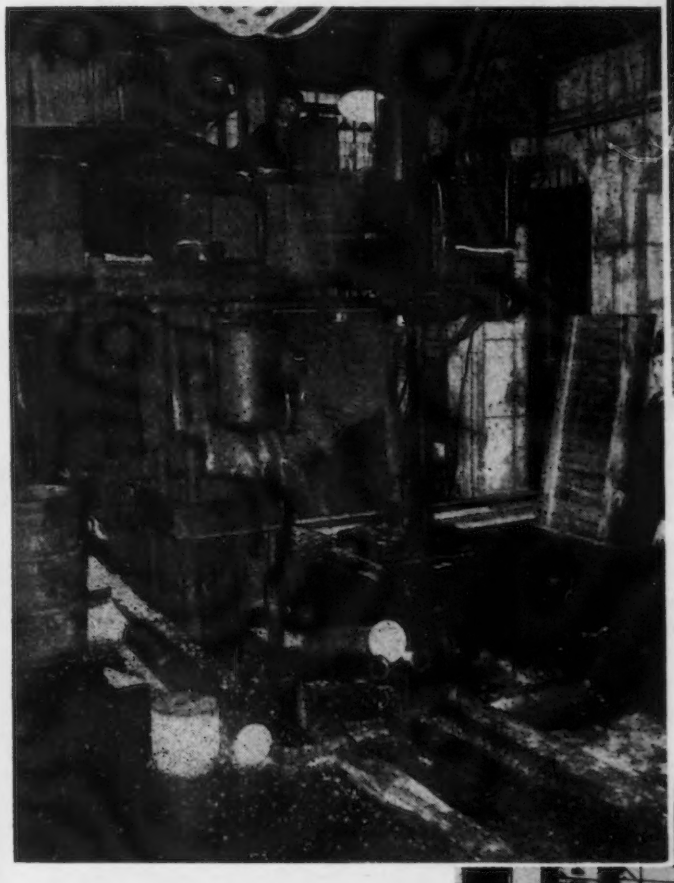
UNDERNEATH the casting platform, the pinch rolls pull a solid 14-in. round of aluminum alloy out of the secondary water spraying chamber at top of the photograph. Delivery speed ranges from 5 to 20 in. per min. A tight fitting round rubber squeegee keeps water from escaping from the spray chamber and also dries the metal surface, which here is quite cool. The bulk of the heat extraction takes place rapidly in the mold chamber.

o o o

RIGHT

UNDERNEATH the pinch rolls is the cold sawing section. This saw unit, especially designed by Rossi Continuous Casting Co., travels down with the metal, with clamps automatically engaging, and the saw cutting in any predetermined length. All saw movements are automatic and follow consecutively once the operator throws a switch which engages the saw to the billet.





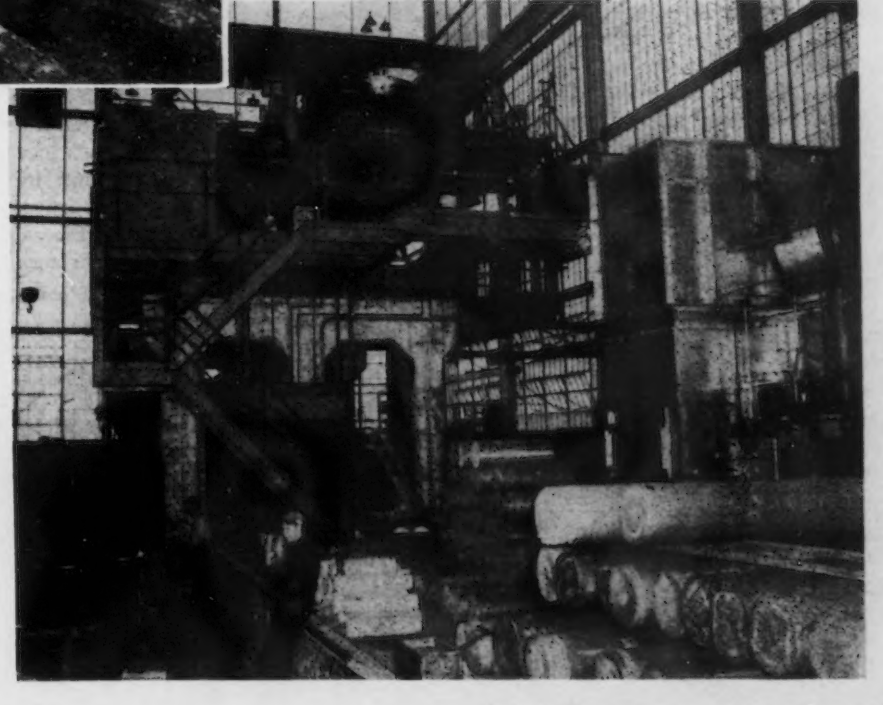
LEFT

LENGTHS of billet, following cutting, drop down onto a chute which directs the billet onto the floor, where a workman piles them. A billet is shown here just as it is about to leave the chute to flop over onto a floor trough. The only metal wasted is the saw chips, shown here scattered over the floor, which are swept up for remelting.

o o o

RIGHT

THE Rossi machine is rather impressive in size, as shown here in side view. In the foreground are long ingots of metal from the Alcoa D. C. machine; farther back are the sawed billets from the Rossi machine. And just so no casting method is slighted, at the extreme left, on a lower level, is an old-fashioned casting turntable, which carries small water-cooled billet molds.



on end. At the Bridgeport Brass plant in Indianapolis this hourly rate has been greatly increased though not for such extended periods. The rates for aluminum run about 40 per cent higher. Each machine normally requires three men for operating it.

As has previously been described, the Junghans mold is ordinary commercial drawn copper tubing, with about ⅛-in. wall section and about 10 in. long. When casting aluminum, an aluminum-alloy mold may be used, much in the same way as does the Alcoa machine. The mold of the size desired is placed in a water jacket, a pack seal being used top and bottom. The cooling water does not feed through this jacket under high pressure, but flow is altered occasionally during casting and, of course, likewise is varied considerably with casting speed or with size of metal section being cast.

The conspicuous and unique characteristic of the Junghans machine is that the entire mold, water jacket and all, moves down at the same speed of the emerging billet for a distance of several inches, and then snaps back to its original position, the snap-back speed being about three times the speed of the billet. The function of this movement is to prevent a constantly changing section of the mold wall to the molten metal, which in turn facilitates freezing a skin onto the molten metal. The infrequent relative movement between mold and metal also tends to minimize skin ruptures. Of course, a great deal of investigation has been given to establishing optimum figures for amplitude of the mold cycle and speed of snapback for different types of metal being cast, cross-section of ingot being cast, speed, etc.

After the cast ingot leaves the mold (or, rather the mold moves upward away from the cast metal), the metal obviously requires considerable additional cooling. This takes place in a circulating body of water, fully enclosed and at the bottom of which is a rubber squeegee seal, which prevents water from running down the ingot and messing up everything below the casting floor. The ingot, as it emerges from the squeegee, is both cool and dry. This secondary cooling arrangement is considerably better than the open sprays used on the Scovill machine which was described in 1940. Another improvement made on a recent machine is the discarding of two holding furnaces for the molten metal, in favor of one, and the use of gravity feed rather than gas pressure feeding through U-tubes, all of which is a trend toward greater simplification and less expense and maintenance.

As shown in the photographs on page 62, the cast ingot passes from the pinch rolls to a lower platform level, at which point a specially designed flying saw slices off the metal in accurate billet lengths, which drop down a skidway to be manually piled.

The structure of the cast metal from the Junghans-Rossi machine is fine-grained, uniform, and controllable in orientation within fine limits by means of adjustment and variation of speed, intensity of cooling, and balance between mold cooling and lower chamber cooling. Long lengths which are perfectly straight attest to the uniformity of cooling and crystallization.

All patent rights to the Junghans equipment throughout the world, excepting Germany, are owned by Irving Rossi, 40 Wall Street, New York. Junghans has been a prolific inventor, and has a multitude of patents covering the successful machine described and appurtenances thereof, and also a number of transcendental whimsies. While many of the foreign patents are of little moment, the numbers of American patents may be of interest, and are as follows: Nos. 2,135,183; 2,135,184; 2,218,171; 2,225,414; 2,225,415; and 2,225,416.

Of the processes at present commercially successful for casting nonferrous metals, several use multiple mold chambers and cast through each at a very slow rate, whereas the Junghans-Rossi machine casts at a very fast rate through a single mold chamber. In the former, the slow speed permits a great deal of the heat to be extracted longitudinally through the metal itself by means of under-the-mold water sprays; and, even though the freezing metal is in constant motion against the mold wall, the relative between the two is so slow as to not form folds and laps. Furthermore, the slow speed permits pretty accurate control temperature gradients, through intensity and location of below-the-mold water sprays.

In the Junghans-Rossi process, however, all the metal passes through one mold chamber, and at a speed that may approach 20 in. per min. This imposes a very severe set of casting conditions.

The Junghans-Rossi mold is relatively quite short, on the order of 10 in. But, more important, due to the method of oscillating the mold, so that the whole mold moves downward at the same speed of the ingot and returning upward at a much faster rate, there is no relative movement between the billet and the mold for the greater part of the casting period. Furthermore, the ability of the mold to freeze a skin on the liquid metal is greatly increased because, due to the mold oscillation, the molten metal line of highest heat intensity is constantly being projected against a different (and cooler) section of the mold. As the area of maximum heat application moves, it gives the previous area of application an opportunity to cool. This is also an argument in favor of making the mold stroke as long as the design of the machine permits, for the longer the stroke the longer the time interval before the maximum heat application returns to a given point and the more time for this point to cool.

The cooling process once begun must continue. This is especially true with respect to the surface. The cooling of the metal (and the resultant freezing) must proceed with an increasing tempo, not only because any interruption of the cooling process has a detrimental effect on the interior of the ingot but because it will have a similar effect on the surface. Shortly after the billet is formed, it shrinks away from the surface of the mold. In the Rossi machine the vertical distance of contact at times may not exceed 3 in., and when casting at a rate of, say, 18 in. per min., the ingot loses contact with the mold in about 10 sec. And, it is during this period that the ingot shell must attain such structural strength as to hold firm during subsequent cooling operations and withstand any frictional effect of the mold surface snapping-back to its starting point.

Only a relatively small amount of heat is absorbed by the mold by radiation during that period while the ingot is still within the mold but with the ingot shell shrunk away from the mold wall. Some additional cooling takes place by water working up into this area from the water chamber located just directly below the end of the mold. However, all this cooling may not be enough to stop the interruption of the cooling process, and it is only the high speed of the ingot down into the cooling sprays that carries it through this short critical zone and prevents the heat from the molten interior from flowing out and softening the shell, with resultant bleeding or spill-outs.

In the high-speed Junghans-Rossi machines, this short period of loss of contact with the mold surface has been one of the most critical of operational problems. In the case of aluminum alloy ingots, the exudations due to ingot shell disintegration are composed of an alloy of aluminum with a lower melting temperature than the alloy of billet being cast. In brass this disintegration may take

the form of an excess of zinc vapor being given off which is deposited on the mold surface or on the ingot itself. Coolant working up into this gap from the water chamber minimizes any interruption of the cooling process and opens the way to the higher speeds of operation.

The ability of the mold to absorb heat during the freezing of the molten metal is related to its ability to rapidly transfer the heat it has absorbed to the coolant on the other side. By placing cooling fins or vanes on the coolant side of the mold it is possible to increase the heat transfer capacity of the mold to more than double. The coolant should be applied to the inside mold surface so that its action will be to wipe away the heat as it reaches the coolant side. The water should be applied tangentially to the inside mold surface in order that the entire volume of coolant circulates around the outside of the mold. Quiescent pools are to be avoided.

In the Rossi machine the molten metal is introduced into the mold underneath the surface of the metal pool, and when brass is being cast a reducing atmosphere is flooded on the top of the molten metal to minimize oxidation. By means of a distributor underneath the metal surface, the incoming metal is flowed radially over the area of the ingot in such a way as to reduce turbulence to a minimum. Furthermore, such distribution assures a homogeneous metal and shortens the time during which the metal is in motion and begins to cool and consequently reduces the possibility of segregation. The radial pouring also projects the incoming metal against the cold surface of the mold and increases the rate of cooling. All mold lubricants used so far leave a deposit of carbon on the mold face while burning, and for this reason the addition of lubricant around the edge of the molten metal pool is as sparing as possible. This cuts down the excessive formation of a carbon deposit which would roughen the mold surface and encourage sticking and also would act as an insulator to reduce heat transfer.

All these factors enable the Junghans-Rossi machine to handle large sections of non-ferrous metals at high speed, the surface of the ingots being smooth, free from laps and folds, and with no bleeding of eutectic. Furthermore, the metal structure in the interior of the ingot is free from shrinkage crevices and porosity, and segregation is minimized. And, the crystal structure is fine and homogeneous in both the lateral and longitudinal directions.

A.S.&R. (Poland-Eldred) Process:

At the American Smelting & Refining Co. plant, Perth Amboy, N. J., an experimental - commercial continuous casting machine has been in operation for some four years, turning out large tonnages of oxygen-free (phosphorized) copper billets up to 3 in. in diameter, which are sawed into 50-ft. lengths for use by A.S.&R., and Chase Brass & Copper Co., primarily in the production of seamless tubing. Surface condition of this metal is very smooth and free from flaws, the metal is very dense and uniform, and in general it is a very high quality product superior to that produced in prior conventional equipment. In fact, the operation is so satisfactory that A.S.&R. will likely install many more similar casting units in a new plant within the next year.

Back in 1940 when a previous report was given on this process, B. E. Eldred had several experimental machines in operation turning out pretty much the same type of metal. Even though Eldred had cast metal section up to 6 in. in diameter, his process was like the A.S.&R. method in that attention was concentrated in metal sections 3 in. in diameter or smaller. Since 1940, however, A.S.&R. and Chase have purchased all the Eldred patents to add to their own patent structure. (See p. 60). Insofar as the writer knows, Eldred's original experimental machines have been scrapped.

Both the Eldred and A.S.&R. (Poland) machines were described in detail in the previous article in THE IRON AGE, April 4, 1940. Both processes specify the use of graphite molds with no lubrication, and because of the use of thick graphite molds the heat transfer was very slow. Thus, the casting rate is equally slow, being on the order of 6 or 8 in. per min. maximum. A curious characteristic of the Eldred and the Poland patents is that they specified diametrically opposite modes of thermal transfer from the molten metal to the coolant. Whereas Eldred particularly specified withdrawing the heat down through the congealing metal, Poland equally specifically designated withdrawing the heat through the mold walls and not through the congealing metal. In any case the difference in opinion is of little moment now.

Because of Eldred's longitudinal heat withdrawal, the crystal orientation of the metal was longitudinal, and because of the slow heat withdrawal the crystal sizes were sometimes enormous. In one instance a copper rod was produced as a single crystal some 32 ft. in length. All this favored the production of metal that was gas-free and very dense, and frequently with exceptional mechanical properties. And, often the metal surface may be so perfect as to make unnecessary a scalping operation prior to subsequent hot or cold working. The A.S.&R. machine back in 1940 was turning out metal with equally good physical and metallurgical characteristics.

A.S.&R.'s machine is essentially a refractory (graphite) chamber holding a sizable quantity of molten metal, with automatic temperature recording auxiliaries for holding the metal within close limits and with facilities to protect the metal against oxidation. In the bottom of this chamber are set four graphite dies along with their individual cooling arrangements. The continuously cast rods are individually withdrawn from these dies and either reeled or cut into lengths by saws. The machine works continuously, day and night, and if after several hundred hours of service a particular graphite die should wear it can be removed and a new one replaced without interrupting the casting in the other dies. The multiple die arrangement of course overcomes the disadvantage of the very slow production of a small cross-sectional cast of metal from each die, and the unit as a whole has a most respectable hourly output, on the order of several thousand tons monthly.

The machine is not in the least temperamental in operation. Naturally, there are innumerable fine points of die design, and inter-relationship between cooling location and speed, and casting speed which have by trial and error been built up into a volume of plant "know how," all of which is a major factor in successful operation of the equipment. A.S.&R. quite understandably shows little inclination to discuss this "know how" publicly.

Williams-Republic Process:

All the machines so far described have dealt with the continuous casting of non-ferrous metals in ingot or billet form. Whereas the Junghans-Rossi machine has been used in Germany for the casting of steel, surprisingly enough no effort so far has been made to give it a whirl for steel in this country.

In the continuous casting of steel ingots or billets in the United States, by far the bulk of experimental work has been carried out by the Williams Engineering Co. of Latrobe, Pa., under the direction of Edward R. Williams, president of Vulcan Mold

Heat Treating

By WAYNE MARTIN
Materials Laboratory,
Sperry Gyroscope Co., Brooklyn

BERYLLIUM copper is a relatively new alloy and has found greater application in the United States than in any other country. This factor is a most fortunate circumstance, for by proper use of this metal certain things can be done in building military equipment that would otherwise not be possible.

Beryllium copper has many good qualities. It can be formed or machined in the soft state and then by a simple low temperature heat treatment, hardened to about 400 Brinell with an ultimate strength of about 200,000 lb. per sq. in. In this condition it will have good electrical conductivity—about 25 per cent that of copper. It has excellent wear characteristics against hardened steel in places where there is a relatively small amount of motion. Under such conditions it often operates well under conditions of poor lubrication and sometimes at somewhat elevated temperatures. Most important is that it can be made into an excellent spring. Its good spring properties are derived from its low drift rate under load, its ability to maintain its

Beryllium Copper

high endurance value under conditions of corrosion that would bring a steel spring to a lower value, and in some cases to its low modulus of elasticity.

Like in any other metal or alloy, certain troubles are encountered in the production and use of beryllium copper alloys. Beryllium copper can be melted under much the same conditions as other copper-base alloys. The 2 per cent beryllium alloy is hot workable at temperatures from 1475 deg. F. to about 1000 deg. F., but it must be considered as a very tender hot working alloy. Small variations in conditions under which the billets are cast effect its hot working properties to a marked extent. These properties are also affected by extremely small amounts of certain impurities.

For additional data on beryllium copper, see "Predicting Spring Performance of Beryllium Copper Wire and Strip," by H. G. Williams, THE IRON AGE, *July 8, pp. 62-67.*

To obtain best hot working properties, beryllium copper must solidify during casting at a relatively high rate. This requires a low pouring temperature and a slow rate of pouring. Under these conditions refractory beryllium oxide defects often form on the surface of the cast billet, which if not completely removed will cause surface laminations in the final rolled or drawn product. Billets must be cast sound, for any pipe in the billet as cast will not weld during hot rolling and will result in center porosity in bars or center laminations in strip. Contaminations of lead, tin, calcium and magnesium will cause hot shortness if present in quantities of a few thousandths of a per cent. After hot rolling, the alloy is given a solution anneal at about 1475 deg. F., followed by quench in water. In this condition it will have a hardness of from 100 to 130 Brinell and can be cold rolled or drawn up to about 70 per cent reduction in area, at which time it must be given another solution anneal and quench to soften it for further cold reduction. It can be bright annealed in dry atmospheres of hydrogen, cracked ammonia or cracked city gas having a dew point of around —40 deg. F. With hydrogen or cracked ammonia atmospheres having a high dew point, a clean red surface is often obtained. This is probably due to the formation of a thin layer of beryllium oxide which has been selectively oxidized before the oxidation of copper. This type oxide is very difficult to remove and has a very abrasive action on forming dies. When annealed in an atmosphere consisting of the products of combustion of city gas, a heavy black scale of copper and beryllium oxide is formed. This is loosely adherent and is easily pickled off.

The precipitation of beryllium copper takes place at temperatures of 525 deg. F. to 700 deg. F. In this temperature range it is believed the cold work in the material undergoes recrystallization. Properly made material can be formed and maintained to very close tolerances during this heat treatment. During the precipitation hardening operation the material

. . . The excellent properties of beryllium copper depend to a large extent on its proper heat treatment. Effects of solution anneal and precipitation hardening on the physical properties and microstructure of the alloy are discussed in detail. The advantages of ternary over binary alloys are also evaluated.

FIG. 5—Hot rolled structure of a 1-in. diameter rod rolled from a 3-in. diameter cast billet. Beta segregation has become beta stringers which are difficult to dissolve in solution heating because alpha solid solution surrounding them has become saturated. At 75 diameters.

FIG. 6—Microphotograph of the same rod as in Fig. 5 but hot rolled to a ¾ in. diameter, annealed and quenched. Light beta stringers are surrounded by light areas of saturated alpha solid solution which has formed from beryllium dissolving out of the beta stringer during previous heating. at 45 diameters.

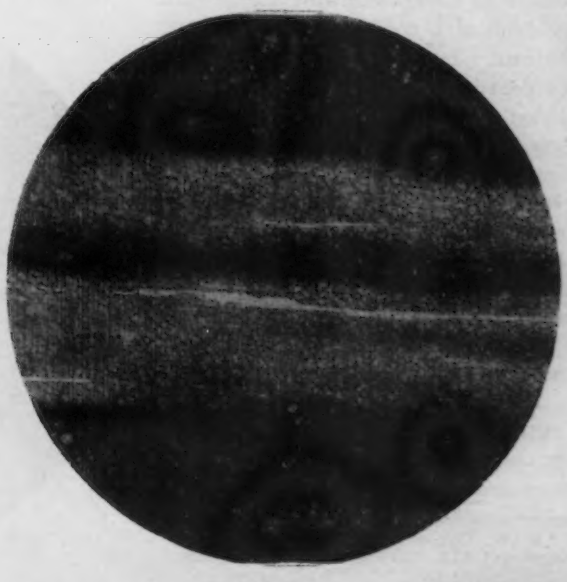

FIG. 7—Shown here is a beta stringer which has remained in a hardened finished part fabricated from cold drawn ¼ in. diameter rod. These beta stringers cause the material to work harden very quickly, making cold forming operations difficult. At 500 diameters.

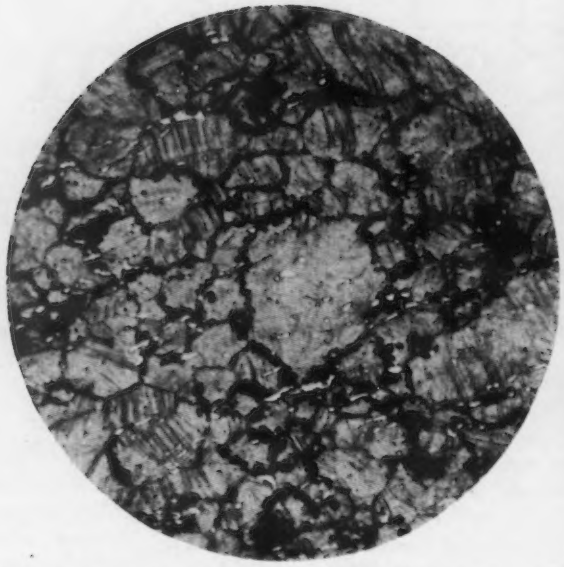

FIG. 8—Precipitation of gamma solid solution in the grain boundaries, as illustrated here, causes severe warping during heat treatment. At 500 diameters.

becomes stress relieved, and this probably accounts for its excellent dimensional stability under load. To obtain optimum properties, the heat treatment must be carefully controlled.

Solution Anneal

The heat treatment is carried out in two steps, both of which are equally important. The first occurs at the rolling mills. An alloy of 1.80 per cent to 2.20 per cent beryllium is heated to 1400 deg. or 1450 deg. F. and held at this temperature until nearly all of the beryllium is in a state of super-saturated solid solution; that is beryllium atoms space at random among copper atoms in the space lattice of copper. The metal is then quenched in water and remains as super-saturated alpha solid solution at a hardness of around 100 Brinell. It can be precipitation hardened directly from this soft condition to around 380 Brinell. However, maximum elastic properties are developed if a certain amount of cold reduction of the material is applied between the annealing operation and the final precipitation hardening treatment. Therefore, strip or wire is usually rolled or drawn to final size after the solution anneal and sold by the rolling mill at a hardness of 160 to 200 Brinell. After forming, the precipitation hardening heat treatment is applied. Properly made alloy will harden at a given temperature over 525 deg. F. to about 400 Brinell; and then with prolonged time at temperature, will begin to soften.

The hardening is due to the precipitation of the gamma phase, a 12 per cent beryllium compound which forms in very small particles. If the heating is prolonged, the gamma particles will coalesce into larger ones and strength and hardness fall off. A typical good precipitation hardening curve is shown in Fig. 1. If the temperature is at 600 deg. F., maximum hardness is obtained at about 1 to 2½ hr. If, however, the temperature is at 700 deg. F., maximum hardness is usually obtained at 15 to 20 min. At this elevated temperature, a greater degree of stress relief is obtained; and as a result, the short time higher temperature treatment is preferable. During this heat treatment, the modulus will increase from 15,000,000 lb. per sq. in. to 18,500,000 lb. per sq. in.; and the drift rate (room temperature creep) will drop to about 30 per cent of its value as cold worked and then will increase with further heating. Electrical conductivity will increase from about 16 per cent to 25 per cent that of copper at maximum hardness; and with prolonged heating, will increase to about 31 per cent at a time when the hardness has dropped off and the drift rate has increased. Material properly made will respond to heat treatment in such manner as to obtain maximum hardness, tensile strength, modulus and minimum drift rate.[1]

If material is improperly solution

FIG. 9—This 0.072 in. wire was cold drawn and then hardened. Cold work after annealing tends to retard grain boundary precipitation. At 500 diameters.

FIG. 10—Grain boundary precipitation in a binary alloy of 2 per cent beryllium and the remainder copper. At 45 diameters.

FIG. 11—Ternary alloy containing 2 per cent beryllium and 0.3 per cent cobalt shows no precipitation in the grain boundaries in the as-cast condition. At 45 diameters.

heat treated, a precipitation hardening curve such as shown in Fig. 2 is often obtained. Here peak hardness is reached in a short time and then falls off quickly. The drift rate never reaches a very low value and the modulus increases slowly. With this type response to heat treatment, it is not possible to obtain optimum spring properties. This is caused by insufficient solution, resulting from too low a solution temperature or too short a time at temperature. It can also be caused by non-uniform precipitation of the gamma phase.

Good and bad results obtained from beryllium copper often result from the past history of the material, and a study of micro-structure can be used to a certain extent to interpret these results.

Microstructure of Cast Metal

The normal cast structure of beryllium copper contains three or more phases. The structure of a 3 in. diameter billet is shown in Fig. 3. The sharp light areas are beta constituent, a eutectic composition containing about 6 per cent beryllium. This was the last metal to freeze. The light mottled zones in between are of low beryllium alpha solid solution. This was the first metal to freeze and contains so little beryllium that only slight precipitation of gamma has occurred on cooling. The dark areas around the beta particles contain about 2 per cent beryllium and appear dark as the result of gamma precipitation which occurred on cooling. The three small particles looking like Turkish characters are beryllium cobalt intermetallic compound. If the rate of solidification is greater, a finer cored structure is obtained. Fig. 4 shows the cast structure of metal of the same composition but cast in a 1 in. diameter chill mold. Here the low beryllium alpha rods are long and narrow and the beta particles are very small. A casting with such a fine structure containing 2 per cent beryllium can be made into a nearly homogeneous alpha solid solution by single heating at 1475 deg. F.

Cast structures resulting from a solidification rate considerably slower than that applied in the structure shown in Fig. 3 will have very large beta segregations. These segregations add to the difficulty in hot working and also remain undissolved as the billet is hot and cold reduced toward its finished condition. The hot rolled structure of a 1 in. diameter rod rolled from a 3 in. diameter cast billet is illustrated in Fig. 5. Here the beta segregation has become a beta stringer. Large beta stringers are difficult to dissolve in solution heating because the alpha solid solution about them becomes saturated.

Fig. 6 shows the same rod as in Fig. 5 after it had been hot rolled to ¾ in. diameter, annealed and quenched. The light beta stringer is surrounded by light areas of saturated alpha solid solution which has formed from beryllium dissolving out

of the beta stringer during previous heating. No more solution of the beta stringer can take place until diffusion of beryllium from the light saturated alpha area into the dark unsaturated alpha area has occurred. Fig. 7 illustrates a beta stringer remaining in a hardened finished part fabricated from cold drawn ¼ in. diameter rod. These beta stringers cause the material to work harden very fast and often result in difficulty in cold forming operations.

Beryllium copper can be held to a very close dimensional tolerance during heat treatment if the hardening operation is carried out in fixtures. In some cases, however, severe warping occurs. This is usually the result of gamma precipitating on the grain boundary, as illustrated in Fig. 8. The cause of this structure is the subject of considerable controversy. We feel that it results from the solution heat treatment of large coils, in which case the rate of heating through the precipitation hardening zone is very slow and the cooling rates during the quench is low due to the large mass of the coil. It has been our experience that strip or wire quickly solution heat treated and quenched in a single strand will not show precipitation on the grain boundary after the hardening operation. Cold work after annealing tends to retard precipitation on the grain boundary. The structure obtained after hardening of wire properly strand annealed is shown in Fig. 9. This material showed the type hardening response as that in Fig. 1 and was very satisfactory.

In this country all of the 2 per cent beryllium copper alloy sold is as a ternary alloy with small additions of colbalt or nickel. In Germany, binary alloy was used before the war. When properly processed, good results can be obtained with either the ternary alloys or the binary alloys. Certain advantages are offered by the use of the ternary alloys. The mechanical properties obtained from heat treating castings of binary alloys in the 2 per cent range are usually very low. This was found to be the result of a gamma precipitation on the cast grain boundary which causes fracture to occur on overloading along the cast grain boundary, showing a large grain cast structure. Fig. 10 shows the grain boundary precipitation in a binary casting. Ternary alloys of nickel, cobalt or iron usually are free from such structure. The absence of this cast grain boundary precipitation seems to be tied in somehow with the presence of the small intermetallic compound of beryllium with nickel, cobalt or iron, which are shown in Fig. 3. Fig. 11 is a low power micrograph of a ternary alloy containing cobalt and shows no cast grain boundary precipitation. Tensile strength as high as 165,000 lb. per sq. in. can be obtained from heat treated castings having this type structure.

In wrought alloys, nickel, cobalt and iron additions act as grain refiners during solution annealing. The grain refining in effect probably is the result of restriction to grain growth caused by fine particles of the intermetallic compound of nickel, cobalt or iron. The grain size of binary 2 per cent alloy solution an-

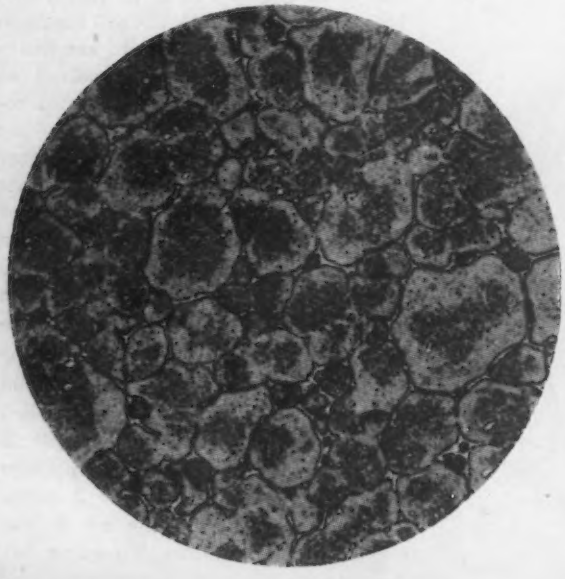

FIG. 15 — Overheated wire showing the formation of beta constituent at the grain boundary. Such burned material should be discarded. At 100 diameters.

nealed for ½ hr. at 1475 deg. F. is shown in Fig. 12 while Fig. 13 shows the grain size of ternary alloy of 2 per cent beryllium and 0.3 per cent cobalt annealed under the same conditions.

The control of grain size can be accomplished in strand annealing of binary alloys, and the use of a grain refiner is not so necessary if the final solution annealing operation is carried out as a well controlled strand heating process. To obtain best response of heat treatment combined with the maintenance of very close dimensional tolerances during hardening, fine grained strand anneal material as shown in Fig. 14 is preferable. In this case, unusually high elastic properties were developed by applying a 60 per cent cold reduction between the strand annealing operation and the precipitation hardening heat treatment.

If the alloy is overheated to about 1600 deg. F. during solution annealing, beta constituent begins to form at the grain boundary, as shown in Fig. 15. Such material is burned and should be discarded. One contributing factor to poor hardening properties not shown by microstructure is too low a quenching rate after solution heat treatment. This can usually be detected by conductivity measurements, the values being somewhat higher than obtained with the proper rate of cooling.[2]

To sum up, the best beryllium copper is obtained by using a fast rate of solidification during casting. This requires cold pouring and preferably small size molds. If this is not consistant with casting shop practice, considerable care need be exercised by the rolling mill during the hot working operation to insure that all beta stringers from the cast structure are dissolved. The final solution annealing carried out by the rolling mill need be of such a quality that the metal after hardening will show little, if any, grain boundary precipitation and good uniform response to heat treatment. Good results have been obtained by batch annealing of coils over a period of years, but strand annealing offers many advantages.

Conveyors Aid Reconditioning of Tool Sets

A TOOL control system, designed to increase the efficiency in grinding, inspecting, storing, maintaining, salvaging and disbursing of cutting tools, has enabled the Grand Rapids Stamping Division of Fisher Body to maintain high machine production, consistently raise the quality of the finished product and decrease the amount of scrap and deviations as well as increase the life of cutting tools.

The system is a recognition of the fact that cutting tools will last much longer and perform better if they are regularly inspected and sharpened. To accomplish this goal, the plan provides that sets of tools be scheduled to the machines according to the operation to be performed on those machines. Each tool set comprises the entire complement of tools necessary to complete an operation or series of operations at one machine, such as a radial drill. The sets are stored and transported in compartmented wood trays. The length of time which a set of tools remains on a job is determined by an actual performance check which governs the replacement cycle. Grinding and disbursement cribs, along with the tool bank storage, are centrally located within easy reach of all machine areas. Dispatching of all tools to and from machines is controlled by the production scheduling department and deliveries are made by routed trucks on a regulated schedule.

Tools returned from a job are received at a window of the grinding room and are placed on a power-driven slat conveyor which feeds them to a roller conveyor, in front of which is an inspection bench. Here damaged, broken and dull tools are removed and a tool replacement slip bearing the codes numbers of the tools is placed in the container, which is identified by operation number.

The boxes are then pushed on a second roller conveyor at 90 deg. to the first. Two attendants pull them off to a bench and replace from finished stock the tools withdrawn in the first section. This replacement section can be seen in the background of the photograph. Loaded trays are pushed on a second power-driven slat conveyor, parallel to the first and serving the disbursement crib. Two attendants remove the trays and place them on storage racks on both sides of the conveyor. Tool sets withdrawn from the racks for disbursement are again placed on the conveyor and carried to the disbursement bench. The end of the line is a short section of roller conveyor onto which the trays are discharged. The entire conveyor system is U-shaped and roller conveyors and power-driven slat conveyors are used in tandem.

Dull tools, after being removed from the sets, are ground and honed, rigidly examined, sealed and replaced in the bank stock to wait future use. The bank stock and the tool set storage areas are separately screened. The tool control system has enabled the Grand Rapids Stamping Division to maintain high production sharpening of precision cutting tools as well as conserve tools and reduce lost time in manhours and machine hours on the production operations.

HERE is shown the mechanical conveyor that carries filled tool sets from the bank stock area, where individual tools have been placed after grinding, to the disbursement crib for storage until needed on a job.

Lubrication in Deep Drawing

. . .What occurs on the die and metal surfaces in deep drawing, and the part that lubrication plays under the pressures and temperatures encountered in this operation, are investigated in this article by Crowther, Liddiard and Marwood, from the British Sheet Metal Industries.

UNTIL recent years the quality of lubricants was judged either by "feel" or by the more certain test of trial on the actual operation in the press. For deep-drawing, the lubricant is so used that existing data or testing equipment such as serves for ordinary lubrication are not applicable. Actual working conditions are so variable that the results are not reliable or reproducible. However, methods of testing are being developed which give comparative information on certain characteristics, though not of the lubricant as a whole.

Blanking can be performed successfully on most metals without much attention to lubrication; mere passing of the strip through oil rollers is often quite sufficient. This also applies to the production of small simple shapes, particularly when the work does not pass through the die but is ejected in the direction of the punch. In drawing, however, the presence of oil or something "oily" does not guarantee success; quality and suitability of the lubricating medium will be the deciding factors.

The art of deep drawing involves so many factors that it is never a simple matter to isolate immediately the cause or causes of difficulties when these arise. It is probable that in many cases a thorough investigation into the lubricant employed would produce immediate and profitable results. Good metal will not draw well with a poor lubricant, but it can be shown that in many cases a poor metal can be drawn when the lubricant is capable of taking on the additional burden. In deep drawing or other operations where similar extreme pressures exist, the pressure developed and, more particularly, the temperature produced so decrease a film layer of lubricant depending only on viscosity, as to produce metal contact rapidly.

This breakdown of fluid lubrication under these conditions is influenced by the distribution of this pressure rather than by the total pressure operating, as will be seen later. It does not appear, incidentally, to be influenced greatly by the relative speeds of the moving surfaces. To summarize, there are three main influencing criteria which result in a completely different form of lubrication from that required, for example, in lightly loaded bearings and described as fluid lubrication. These differences are: The total operating pressure; the distribution of that pressure; the temperature rise.

The situation, therefore, which exists during the actual deep drawing operation between the surfaces of the punch, cup, and die would more accurately be described as boundary lubrication, since the film of oil or lubricant remaining will be at most a few molecules thick, while in unfavorable conditions it will be so extended as to break and produce metal-to-metal contact with fouling of the punch or die.

It might be helpful at this stage to examine the conditions which exist in deep-drawing operations; these support the view that boundary lubrication is, in fact, the only condition which can exist. In the first place it is essential to realize that the metal of the die and that of the blank or cup to be drawn are not plane surfaces. They may be polished according to engineering standards, but even with the low-power of a microscope they are seen to be uneven, with pits and peaks covering the surfaces of the metal. Even the most highly polished surface obtainable would still be covered with considerable undulations in terms of molecular dimensions, and high-pressure lubrication is concerned with molecular forces.

Hence when two metal surfaces are placed in contact they will meet only where the peaks of the undulations project, and the *actual* area of contact is therefore an extremely small proportion of the *apparent* area of contact. Dr. Bowden, of the Laboratory of Physical Chemistry, Cambridge University, has indicated that in an apparent area of one sq. ft. of highly polished metal surface, the actual area of contact amounts to only 0.0001 sq. cm.

Before considering the situation at these regions of contact it is necessary to consider the condition of the

molecules at the surface of the metal. The molecules of any material, whether solid or fluid, have a surface attractive force which will extend outwards from the air-metal interface. Within the body of the metal this molecular attraction is represented by the force of cohesion when the molecules themselves satisfy the attractice forces of their neighbors. These forces of attraction are a result of the proton and electron arrangements within the atoms, and at the surface, where the mutual forces are uneven, a zone of attraction exists, pulling and holding other materials to the metal.

Oxygen Film Produces Adsorption

Oxygen from the air may be attracted to the surface, and a thin layer of the gas will be held on to the metal surface, producing the condition known as adsorption. It is on this physical principle that boundary lubrication depends, making deep drawing possible. The region of attraction is very limited, and at the most is only 1 to 3 Angstrom units thick. The rate at which the attractive force falls off as the distance increases from the molecules at the surface is very great, and beyond the distance stated above is negligible.

Air, water, grease, in fact anything which is available, will be attracted towards the metal surface, and will give some degree of protection to it. Two metals coming into contact are almost bound to have adsorbed layers, and at first, if there is no pressure, there will be no actual contact between the metal molecules. But this is largely conditioned by the degree of attraction involved, since materials which are only loosely adsorbed will soon be displaced by others more readily attracted by the surface molecules of the metal. For example, an adsorbed surface of oxygen would most probably be immediately displaced when metals came into contact, since the metal-to-metal attractive force would be greater.

Molecular Fusion

Provided, then, that the adsorbed layer is not mechanically disrupted, it will remain intact until some other material for which the metal surface molecules have a greater affinity comes within the zone of attraction. When this condition arises the initially adsorbed material will be displaced in favor of the latter. Molecular fusion occurs, the binding forces being a result of the electrical charges within the atoms. If the new material which becomes adsorbed is another metal, this molecular fusion is tantamount to welding. In other words, at the areas of true contact, fusion of the two metals occurs, inducing the state of friction. In deep drawing, one of the surfaces (that of the die) is fixed, the other (that of the surface of the metal being drawn) is moving. Hence it is to be expected that with sufficient load the welding which develops at the metal contacts will immediately be disrupted; the greater the number of such contacts, the greater the load required to disrupt, and thus to maintain continuous movement of the work.

If the metal surface is rough, the drawing load will be localized in a number of very small areas, resulting in extremely high pressures at these places. Under these circumstances the possibility of rupture of the lubricant will be greatly increased.

This leads to the conclusion that it is preferable to draw a metal the surface of which is smooth.

In most cases the retention of this smooth surface throughout various operations is not possible, as it is destroyed by annealing in an oxidizing atmosphere and by subsequent pickling. With bright annealing, however, the smooth surface can be retained through many operations.

There is yet a further factor to consider—that of the temperature which develops at the area of drawing and which is a probable cause of many drawing problems. It has been shown in a series of experiments by Bowden that when one surface slides over another there is considerable temperature increase with increasing load. Temperatures may easily reach the melting point of one of the metals even at comparatively low loads. He and his co-workers were able to show that the material which had the lower melting point is the one which will be polished, the other being little affected. If the temperature developed reaches the melting point of one of the metals it will remain at that temperature, and that metal will be polished. This has a very important bearing on deep drawing, since a melted metal surface will flow into the undulations of the higher melting metal and result in a greater area of actual contact. This material upon resolidification takes on a new form, previously crystalline metal becoming amorphous and depositing in the pits between the melting peaks. It forms what is known as the Beilby layer, and in such a form alloying of metals occurs more regularly. It has been shown, however, that temperature and not hardness is the controlling factor, and even soft metals can polish harder metals, provided the former have a higher melting point.

It is useful at this stage to consider the "stick-slip" theory which has been put forward by Bowden and successfully demonstrated by him and his coworkers. Two metals sliding over each other do so in an action which is not continuous, but takes the form of a "stick-slip" motion. In other words, the motion of the one metal over the surface of the other is intermittent, pausing, then moving, pausing again, etc.

Stick-Slip Theory

The frequency of the cycle of slipping and sticking varies with the metals in contact, and it appears to be influenced by the melting points of those metals. Thus with hard metals in contact with each other the frequency is large and regular. With a softer metal in contact with a hard metal there is a similar frequency, but larger differences in the friction are to be noted.

These workers have gone so far as to suggest that the frequency of the "stick-slip" cycle may be responsible for inducing vibrations in the machinery itself on the principle of resonance. More recently Bowden and Leben claim that this "stick-slip" action is more prominent with mineral oils, and is inclined to disappear with fatty materials, particularly as the chain length of the molecule increases. In other words, the "stick-slip" motion only appears with non-adsorbed or weakly adsorbed lubricants.

The important point is that a higher rate of wear is to be observed with "stick-slip" sliding than with continuous sliding.

A further interesting observation was made by Bowden and Hughes, who stated that the co-efficiency of friction of two absolutely clean surfaces sliding upon one another is often 20 times as great as when the surfaces are cleaned by normal methods. They consider that a film several molecules thick must appear between the metals before the normal co-efficiency of friction is to be observed.

Basic Lubrication Requirements

The basic requirements for successful deep-drawing lubrication can now be stated. These may be enumerated as follows: (1) The area of actual contact between the metals must remain very small; (2) the metals should be prevented as far as possible from coming within the zone of attraction of each other; this might be

done by employing a material for which each metal has a greater affinity than it has for the other metal; (3) the temperature must be kept to the minimum by, for example, the presence of sufficient low melting metal.

Consider the practical developments of this summary. It has been suggested above that if a material could be found for which the metals have an attractive force greater than that which they have for each other it could prevent metal-to-metal contact. Such materials are to be found and are used in deep drawing lubrication, one example being a long chain fatty acid, when the attractive force is due to the acidic grouping at the end of its chain. It is an essential requirement that the successful material shall have some combining group within its structure, but this is not a question of unsaturation, since stearic acid, a fully saturated acid, is an excellent drawing medium, provided pressures are not too extreme.

The paraffin hydrocarbons are not suitable, since they have no combining group, and while they are readily adsorbed on to a metal surface, they are easily displaced by another metal surface. Other straight mineral oils, including the naphthenic mineral oils, suffer from the same defect. Since these latter contain cyclic groupings, they are unsaturated and also cannot form a film of laterally oriented molecular chains on the metal surfaces. They may therefore be expected to have even less lubricative effect than the paraffin hydrocarbons which are capable of forming such chains.

The long chain fatty acid referred to above will be oriented upon the metal surface in such a way that the hydroxyl grouping is directed to the metal, and the long chain of hydrocarbon groupings away from it. This latter will protrude for some 20 to 30 Angstrom units from the metal, and hence beyond the zone of attraction of the metal surface molecules. It will not be absolutely vertical, since the polar groupings will force the non-polar chains farther apart from each other than would otherwise be the case and their lateral forces upon each other would not be so effective. Hence they will take up an angle to the vertical if the polar grouping is not too large in view of the repelling forces which will operate on the non-polar part of the molecule. It will then keep other molecules, including those of other metals, at a sufficient distance from the first metal to prevent fusion, and this quality is amplified by the fact that the other metal will bear a similar film. There is most probably some bending of the long chain, and this will be more pronounced at the greater pressures. Fusion of the long chains will also develop, but the linkage produced will be weaker than that between the hydroxyl grouping and the metal, so that when the metal moves on a break will occur at the bond of the hydrocarbon groups, this fracture being produced with a comparatively small loading. This theoretically ideal condition is, however, qualified by a further factor—the extreme pressures occurring in deep-drawing operations. These are sufficient to force the metal surfaces so close together that the adsorbed film is squeezed out and the metals are brought within each other's zone of attraction.

It must be remembered that these pressures, although usually judged as operating over the whole apparent area of contact, are really operating over the very minute area of actual contact; and under these conditions the load per unit area is extremely high. As a direct result of this the temperature increases until it reaches the melting point of the lower melting metal, and will then remain stationary; this temperature will cause a flow of the metal, to give greater area of contact, and thus a greater distribution of this high temperature. Under extreme pressures, then, seizure will result, being at first apparent as scoring and then as seizure between tools and work. Simple long chain fatty acids under these conditions are quite unsuitable, and the problem is therefore more complex than might at first appear.

It has been previously stated above that if a metal can be used which melts at a lower temperature than the metal of the tools or of the drawn work, the temperature will remain at this lower melting point, provided there is sufficient of the selected metal remaining in the solid form. Once it has all liquefied, the temperature will again commence to rise. Physical considerations, such as viscosity, melting point, boiling point, etc., limit the choice, but certain metals have proved extremely successful, for example, lead and tin.

Other methods are employed to overcome the problem, one being the employment of a protective film often inorganic in character, such as the chloride and sulphide films on the metal surfaces.

A further method makes use of solid adjuncts. These, being solid, have internal and cohesional forces which show considerable resistance to disruption of the metals. Most of these solid lubricants have crystalline structures, and the crystals may be disrupted. The more successful of these solid lubricants show easy cleavage of the crystal along one plane parallel to the direction of movement of the metal surfaces. The general methods of lubrication are summarized in Table I, which is designed to indicate relatively the physical forces upon which lubrication depends.

Under ideal conditions, the film of lubricant will be continuous and unbroken over the whole surface of the metal, particularly, that is, as far as the outside of the cup is concerned.

When breakages of the film occur, difficulties result which may take the form either of scoring down the side of the cup, or of tearing at sharp corners where, by reason of the break in the film, the metal has ceased to flow freely and has piled up until it is torn by the force over the die edge.

It is a short-sighted policy to omit lubricant from the punch and inside of the cup. This is often done, since

TABLE I

Types of Lubrication

(1) No lubrication.	Very light loading (cart wheel on the road).
(2) Lubrication:	
a. Fluid lubrication.	
1. Simple fluid buffer with non-oriented molecules.	Light loading.
2. Long chain molecules showing orientation.	Medium loading (gear wheels, light pressings).
b. Boundary lubrication.	
1. Polar chains becoming adsorbed at polar head, with oriented chains.	Heavy loading (deep drawing of thin metals).
2. Use of protective films.	Extreme loading (deep drawing of heavy gauge metal, or hypoid gears).
3. Use of lower melting adjuncts.	
4. Use of solid adjuncts.	

it is possible to draw the metal like this with apparent success. The first and most obvious difficulty is in removing the cup or tube from the punch, particularly when the wall is thin. A more lasting effect is the excessive wear of the tool. On considering the condition, it is apparent that similar forces are in operation on both punch and die, although the greatest movement takes place on the die surface. The increase in temperature of the tool in question is offered as further evidence of the need for overall lubrication.

These remarks apply also to reforming operations, although it is rare in such cases to find lack of lubricant. The authors have experience of instances where in severe reforming operations fouling of the punch has been caused by inadequate lubrication.

Various measures may be taken to amplify resistance of the lubricant to extreme pressures. It will be sufficient if it be remarked here that under the extreme conditions of boundary lubrication present in the deep-drawing operation, the relationship between the lubricant and the metal will depend very largely upon the affinity of the lubricant for the metal, producing an adsorbed film of lubricant upon the metal as a result of atomic linkage between the substances.

Hardening and Brazing in Tocco Unit

A SIMPLE change in design of a Tocco induction fixture made possible a rapid "three-in-one" heat-treating operation that is saving steel and relieving forging facilities for a midwest automotive manufacturer producing diesel engines for Army tanks. Used on vital engine balancer shafts, the Tocco induction treatment hardens a bearing surface and a thrust face while brazing a collar to the shaft. The entire three-way operation is done simultaneously in 41 sec.

Originally, the bearing end of the balancer shaft was machined down to size from bar stock which is the same diameter as the collar which forms a thrust face at the end of the shaft. It was necessary to copper plate the end and to carburize the piece.

A second method for producing the shaft was introduced specifying hot upsetting from nominal diameter stock, machining the piece, Tocco hardening the bearing surfaces and grinding to finish.

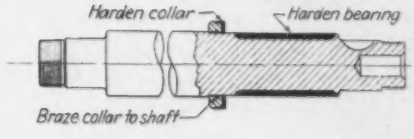
Then a third production procedure was adopted by redesigning the Tocco inductor to include brazing a separate collar to the shaft, as shown in Fig. 1. It is this current operation that has effected savings in material and time. Although the hot upsetting process used in the second method described effected an economy in steel, the current use of a separate collar has helped to alleviate critical forging facilities and save on machining time as well. Furthermore specifications calling for Tocco hardening eliminated carburizing material, the time required for packing, and several previous operations.

The collars are now turned out quickly on a screw machine, carburized separately, and then positioned on the shaft preparatory to heating with the brazing material placed in a groove in the collar. The collars are 2 1/16 in. in diameter with a face 9/32 in. deep. Heat for hardening the bearing surface, which is 1½ in. o.d., and 2⅞ in. wide, reaches 1550 deg. F. At the same time, the thrust face adjacent is also heated to that temperature in order to penetrate to the silver solder for the brazing of the collar. The water quench does not affect the braze, as the inductor is designed to act as a shield.

Thus, as the bearing surface and the thrust face are hardened, the collar is brazed uniformly to the shaft. The entire application requires only 41 sec.

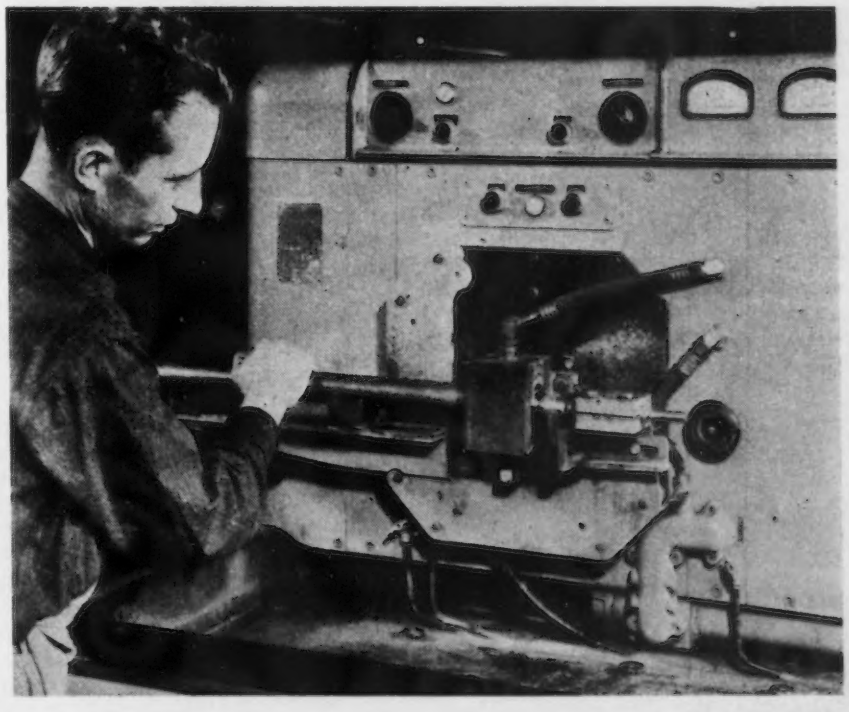
A hardness of 56 to 58 Rockwell C on the thrust face and 50 to 55 Rockwell C on the bearing surface is effected, and there is no distortion. The Tocco machine shown in Fig. 2, on which these operations are performed, is a standard 80-kw. two-station unit.

FIG. 1—Cross-section showing the three areas on the balancer shaft which were treated in one 41-sec. operation. A bearing surface and a thrust face are hardened while a collar is brazed to the shaft.



o o o

FIG. 2—Operator inserting balancer shaft in the Tocco inductor block for hardening of two bearing surfaces and the brazing of a collar to the shaft in one 41-sec. cycle. The small block at the end of the shaft is merely a steady rest.

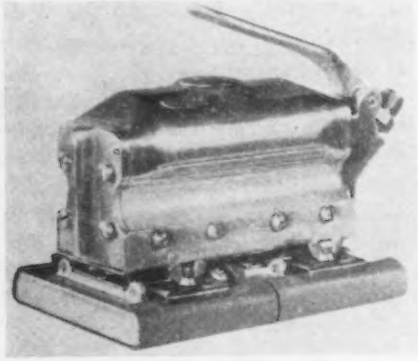


New Equipment . . .

. . . . Finishing

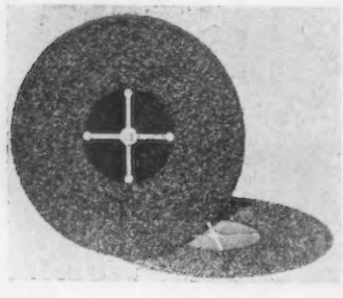
. . . Recent developments in cleaning and polishing machines, corrosion control material, protective coatings and industrial paints are described and illustrated in the following pages.

DESIGNED and built for hand sanding and finishing operations, the sander manufactured by *Sundstrand Machine Tool Co.*, Rockford, Ill., is available in a light weight Model 1000. It has a speed of 3500 oscillations per min. and can be equipped with different types of sandpaper attachments for large or small, wide or narrow, flat or curved abrading surfaces on metal, wood, plastics or composition. The machine is controlled by a palm lever fitted at top of the machine housing. When gripped, the reciprocating action of pads starts and stops automatically upon release.



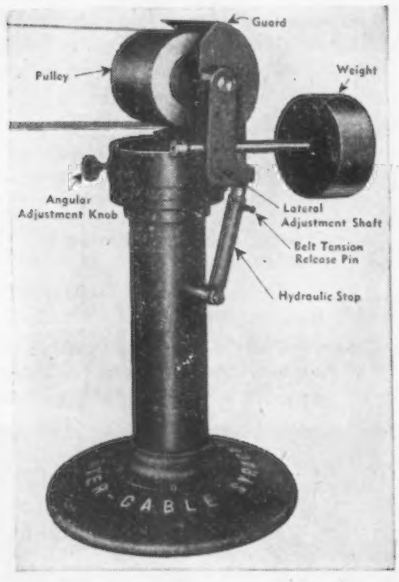
Abrasive Sanding Disks

THE abrasive sanding disks manufactured by *Fibre Abrasive Corp.*, 1129 East 74th Street, Chicago, are made of aluminum oxide grit firmly bonded with a special heat-resisting resin to a chemically treated, super-pliable fiber back. The "Marvel" disks are said to be extremely hard and tough and require less cleaning and replacement than conventional glue-bonded disks. They are available in diameters ranging from 6 to 30 in. and in all grit numbers.



Backstand Idler

TO adapt grinding and polishing lathes to abrasive belt grinding, the *Porter-Cable Machine Co.*, Syracuse, N. Y., has developed the Model ABS backstand idler, which makes possible the use of an endless metal cutting abrasive belt. The unit is recommended for grinding welds, flash, generating radii, flat and edge work, cleaning up, polishing, etc. Belts up to 6-in. width can be used.



Magnetic Polishing Lathe

THE Lima Electric Motor Co., 2801 Findlay Road, Lima, Ohio, has put on the market a magnetic polishing lathe designed to eliminate the difficulties encountered in holding odd shapes or sections. It holds parts from 1½-in. diameter up on a magnet chuck and leaves no marks on highly finished parts. The unit is furnished with either single or two-speed motor. A self-contained rectifier unit supplies d.c. current to the chuck. Interchangeable faceplates and register plugs make it adaptable to various types and sizes of work. It can be supplied in either pedestal or bench type.

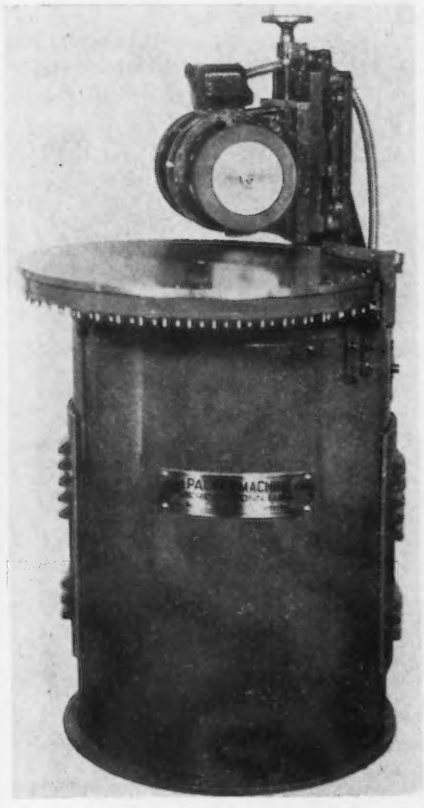
Polishing Lathe

A COLLET head lathe unit for polishing, finishing, filing and burring operations has been announced by the *Reynolds Machinery Co.*, Prov-

idence. Any standard motor may be used and a single lever control for starting, stopping, applying brake and opening and closing collet is provided. The machine uses a No. 5c Rivett collet. The spindle nose is threaded to provide for use of a 4-in. chuck.

Deburring Machine

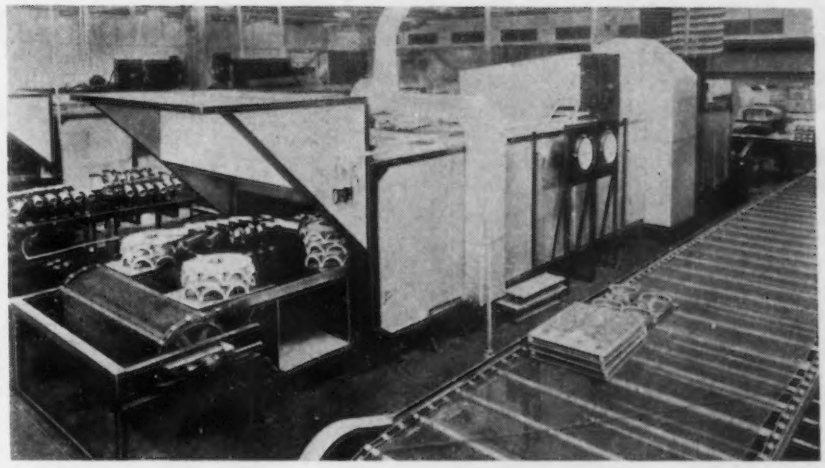
THE No. 7 Packer-Matic machine has been developed by the *Packer Machine Co.*, Meriden, Conn., for continuous rotary grinding, deburring, polishing or buffing. Its construction is rugged and compact with built-in flexibility for a wide range of



sizes. A second head or wheel can be attached for producing multiple operations. Attachments are provided for automatic discharge of work and hopper feeds can be used wherever practical. Wheels may be mounted either in vertical or horizontal positions.

Paint Baking Oven

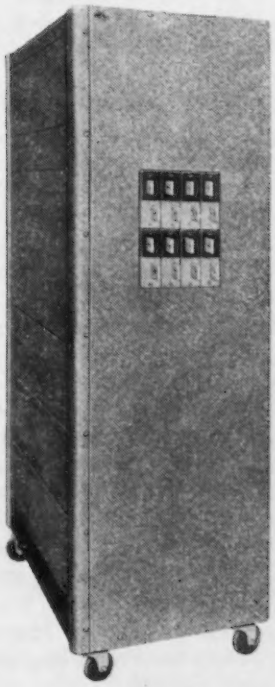
A CONVEYOR type oven for baking paint on miscellaneous aluminum alloy parts of different sizes and weight has been built by the *Gehnrich Corp.*, 35-10 Skillman Avenue, Long Island City, N. Y. The dual panel steel insulated oven houses a flat screen belt continuous conveyor 40 ft. long x 5 ft. wide, which is supported on cross flights fitted into heavy duty roller chain driven by



sprockets through a speed reducer and a variable speed drive. Heated air at 150 to 225 deg. F. is supplied to the oven in sufficient volume to volatilize the paint solvents. The temperature is held within close limits by automatic indicating and recording controllers and heating protection is provided by safety switches for shutting off heating load and motor circuit in the event of power or fan failure.

Plating Rectifier

THE Model 86 multi-plater, put on the market by *W. Green Electric Co., Inc.*, 130 Cedar Street, New York, is claimed to incorporate in one cabinet mounted on caster wheels, eight separate selenium rectifier sections, each with a capacity of 6 volts 500 amp. d.c. These sections, with separate input and output terminals, may be interconnected in several hundred different combinations, to con-



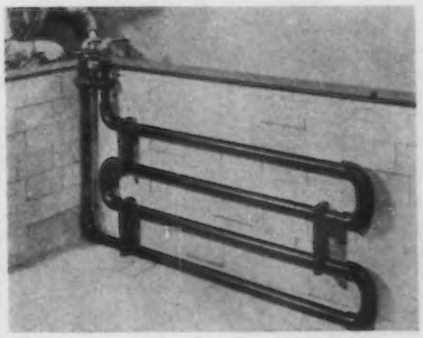
vert either 220 or 440 volt 3 phase a.c. to d.c. power for electro-plating, electro-cleaning, chromic or sulphuric acid anodizing, etc., in tanks, barrels or automatic machines. It is claimed the unit will deliver 4000 amp. at 6 volts and can be adjusted to deliver 2000 amp. at 12 volts, 1000 amp. at 24 volts, or 500 amp. at 48 volts.

Plating Solutions

A SPECIAL alkaline zinc plating solution has been developed by the *Hanson-Van Winkle-Munning Co.*, Matawan, N. J., with which is used S-B addition agent for producing satin-bright to bright depositions, the degree of lustre depending on the choice of operating conditions. Several lead solutions have also been developed, among which is an improved concentrated Protecto lead solution. A working solution is obtained by adding three parts of water to one part of concentrate.

Carbon Heating Coil

A GRAPHITIC carbon heating coil for heating tanks containing acid cleaners used to prepare aluminum aircraft parts for spot welding has been developed by the *Heil Engineering Co.*, 12901 Elmwood Avenue, Cleveland. It is claimed that the coil, which is made in standard sizes and in any shape for a wide variety of uses, is impervious to chemical action and has a heat conductivity between



that of steel and copper. Steam jets of the same material can be supplied for direct introduction of steam to perform both heating and agitation.

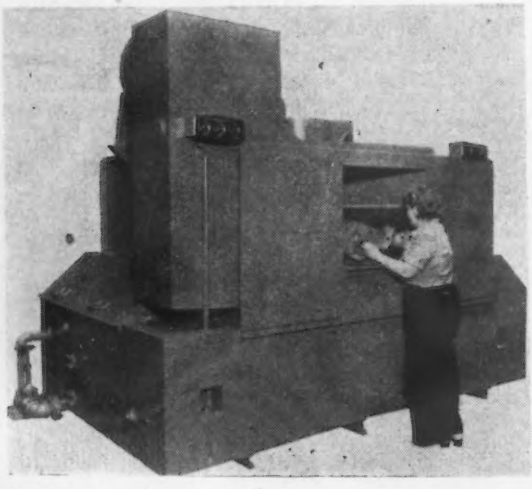
A new type of "sawtooth" extruded lead anode for electroplating has also been developed by the company. The multi-angled surface is said to give 50 per cent more area than a flat anode. One side has ten edges and the other side has a central spine ½ in. thick running down the center. The spine connects directly with the hook, providing greater current carrying capacity from top to bottom.

Plating Rack Covering

MADE from Koroseal, a plasticized polyvinyl chloride thermoplastic material, two new products for covering plating racks are announced by the *B. F. Goodrich Co.*, Akron. Koroseal Tape RX can be used for practically all kinds of plating service, since it is resistant to all plating solutions, including chromic, alkali and acid dips. Koralec RX is a solution of Koroseal. In some applications the two can be used together, with the tape being applied after the rack has been coated with the solution, while in other cases they may be used separately.

Cabinet Washing Machine

THE segmented cabinet washing machine, manufactured by the *Industrial Washing Machine Corp.*, New Brunswick, N. J., consists of a large mesh turntable which rotates slowly. Surrounding it is the housing, which is portioned off into various combinations for washing, rinsing (or slushing) and drying. The parts to be cleaned are placed either directly upon the mesh or on the fixtures. As the turntable rotates it carries the work through the cleaning operations and returns it to the loading point.



Cleaning Tank

TWO hot liquid dip tanks in one portable unit feature the Twin Dipmaster developed by the *Aeroil Burner Co.*, West New York, N. Y., which enables the operator to clean and rinse metal parts without the necessity of carrying them to a second tank for hot or cold rinsing. Two removable immersion tube heating units deliver all the heat in the cleaning solution and rinse water. The company has also developed the Waxmaster tank units, in which metal parts may be dipped in a heated wax compound for protection against salt water, high humidity, moisture and long-time storage.

Anodizing Racks

A COMPLETE line of standard racks and fixtures for use in the anodizing of aluminum parts such as sheets, skins, tubings, castings, bar stock and a variety of small items has been brought out by *George L. Nankervis Co.*, 5408 Commonwealth Avenue, Detroit. Special features can be developed to specifications.

Zinc Anodizing Bath

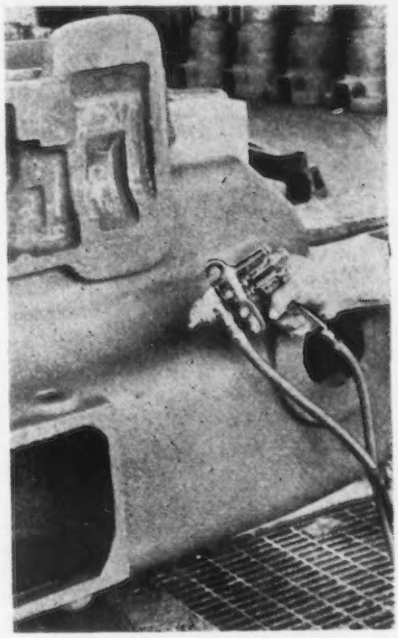
AN easily controlled means of increasing the rust-resistance of zinc coated steel parts and of retarding the formation of white zinc corrosion products has been developed by *United Chromium, Inc.*, 51 East 42nd Street, New York 17. It is applicable to zinc plated on any metal and in some cases to zinc-base die castings. Parts finished in Anozinc baths have stood up in excess of 200 hr. under the Army-Navy salt spray test. It is available in a dark, semi-lustrous black and a brassy, slightly iridescent yellow. Improved appearance and longer life are claimed.

Metal Coating

A NON - ORGANIC coating for metal in a broad range of colors has been brought out by the *Pemco Corp.*, Eastern & Pemco Avenues, Baltimore, under the name of Poroseal. It is not a paint, although it can be used in one or two coats on sheet steel and malleable or cast iron either by spraying or dipping. It is claimed to be highly resistant to corrosion, acids, solvent, heat and abrasion and is non-toxic, homogenous and odorless.

Machine Tool Finish

THE research laboratories of the *Sherwin-Williams Co.*, Cleveland 1, have developed a new "pebble" finish for machine tool surfaces which not only uses less finishing materials



but can be applied in ⅓ to ½ less time. It is said to be possible to finish a machine tool in three operations instead of seven. The pebble finish effectively hides scratches, grinding scars and other surface defects.

Plastic Dye

TO fill the need for a dye that could be easily, quickly and effectively applied to plastics such as Lucite, Plexiglas and Tenite, which would remain full toned and permanent without wearing or rubbing away and would preserve the plastic's original gloss and hardness, the *Technical Color Div.* of the *Krieger Color & Chemical Co.*, 6531 Santa Monica Boulevard, Hollywood, Cal., has developed Lucidip. Twelve colors are available and the different colors may be intermixed to form special colors or blends.

PARISH STAMPINGS

The railroads of the country have proved themselves miracle workers in the transport of war goods. An equally remarkable accomplishment is heralded for the post-war economy.

Soon to be on the drafting board are designs for rolling stock that will make possible transportation of passengers and freight at the lowest per mile cost ever known.

Steel, as always, will be the basic element in this further advance; for steel, properly alloyed, or properly surface protected, provides resistance to the elements beyond that accomplished by any other material.

Steel also provides resistance to fatigue, to shock, to temperature changes, that is bound to make it the reliance of the future just as is has been of the recent past.

Pressed Metal Parts and stampings will be used by the railroads, and by numerous other industries of the country because of their low cost, their broad range physical characteristics, their aid in the creation of beauty, and for their other well known qualities that has called for the tonnage in the past.

Parish Pressed Steel engineers will be found cooperative and helpful. Why not call on us while your plans are in the preliminary stage.

• Detroit tool shops again are filled, as aircraft companies order . . . Caution rules helicopter outlook . . . Industrial stylists show wares and indicate the trends ahead.

DETROIT—Tool shops here are undergoing another of their volatile swings. At the turn of the year they were edging toward the easiest level of operation since the war begin. Now they are suddenly loaded up with work again, and some few shops are booked to an extent that they are not taking any new business right now.

The reason is the release and near-release of several large aircraft tooling jobs. These involve both airframes and engines, and the tooling programs for them run high into the millions. There are four major jobs of this size on which capacity is being sought and filled in Detroit, and work on others is also being placed in lesser measure.

This presages new aircraft production programs late this year or perhaps early in 1945. There will be big cargo planes coming out of this tooling, new combat ships, and larger powerplants to go with them.

Trade gossip is that at least three motors have been developed which turn up far more horsepower than ever before put out of aircraft power packages. Tooling for such big motors and the big ships to go with them will take up any slack anticipated for the equipment shops for quite a little time to come.

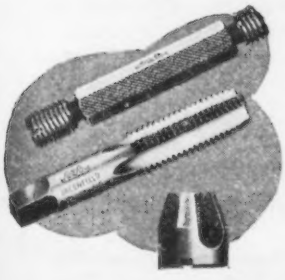
On the subject of aircraft, there are other well-based rumors percolating through Detroit these days. One concerns Chevrolet and Buick, whose overall commitments for Pratt & Whitney jobs were recently reduced. Since then Buick has taken on production of the cargo plane engines heretofore made exclusively in this area by its General Motors cousin. The expectation is that while Chevrolet cuts down Buick gradually will further increase this output until it is the sole automotive manufacturer of the type. To fill the gap caused by this transfer, Chevrolet will go into production on a somewhat more advanced version of the job which it is now producing. As a result, the layoffs in those two companies and the curtailed ordering from parts and materials suppliers will likely be of rather short duration.

WITH regard to another kind of aircraft development, confirmation was forthcoming this week of gossip that Warner Aircraft Co. has been tinkering with an engine planned for helicopter installation. The confirmation came in the form of an official slap on the wrist delivered by WPB which alleged that Warner, in delivering an apparently experimental helicopter engine on a top preference rating, had bypassed earlier orders carrying equally high priority. Warner was reported put on probation until April 26, 1944, along with several other Detroit firms found guilty of equally unintended WPB regulation violations. Warner's experimental work has roused hopes among its well-wishers that the concern may finally fall into some engine production of significance.

But helicopters, it might be stated, lack in informed quarters the enthusiasm manifested for them in the Sunday supplements. One expert said privately last week that in his opinion the helicopter, as it stands today, has not progressed beyond "an advanced state of pure research." This speaker is quite close to the entire helicopter scene. In equally informed other quarters there is general regret that recent publicizing of helicopter accomplishments has bedazzled the nation into expecting a vertical flight age the day the war ends. No such era is in prospect, the experts agree, for a number of years to come. Don't make reservations yet on those bus-helicopter lines scheduled for intrastate runs. The day is coming, quite likely—but not this week or next. Notwithstanding the down-to-earth helicopter limitations as they exist today, the wave of general interest in the device will undoubtedly continue, and postwar speculative enterprises may spring up as they once threatened to do on autogiros. Incidentally, basic

NAPIER SABRE ENGINE: *In late 1936 Napier Co. completed development of the twin crankshaft airplane engine and built a 2000 h.p. model. This engine, the Napier Sabre, was officially approved in 1940. Women workers here are inspecting many of the parts that go into this engine.*

THE WOUNDED PLANE THAT *Flies* AGAIN



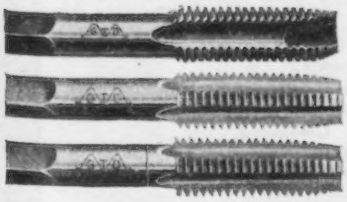
The Germans and the Japs do bring down some American planes — but they'd better be sure they fall in enemy territory. Otherwise, many of them have a way of coming up again, to do battle once more.

The damaged planes — called "hangar-queens" — are kept intact, till their undamaged parts are needed to repair another plane.

What makes possible this free interchange of parts is that miracle of modern manufacture which we're prone to take for granted — STANDARDIZATION.

The striking story of the hangar-queen, made possible by standardization, only highlights its benefits to the world in *time of peace.* For not until the use of interchangeable parts made mass production possible did all the people begin to share the comforts formerly available only to the few. *And the end is not yet.*

Standard Threads - SAVE TIME - SAVE MONEY!



GUN TAP
●
CUT THREAD TAP
●
GROUND THREAD TAP

Here are 3 different types of Tap, all of the same size. One of these will best suit your requirements. You'll save money on your work if you first determine which of these types you should use, and thereafter specify this type for that job. This is "Standardization" in practice.

GREENFIELD TAP AND DIE CORPORATION GREENFIELD, MASSACHUSETTS

helicopter patents stem from the Cierva rights, which are licensed to Pitcairn and embodied in that company's autogiro.

THERE are probably a dozen big league industrial designers in Detroit, and an additional score or so on the fringes of prominence. The dollar value of the products which they style is undoubtedly far above that of the more prominently publicized eastern designers, for they turn out the major share of the automotive and industrial developments of their geographical area. Last week the newly-organized Detroit Industrial Designers Association sought some public recognition for its members with a rather provocative display of models and sketches.

There was plenty of blue-sky dreaming in many of the exhibits—"air-brush engineering," as many hard-bitten technicians call it. There were aircrafts designed for appearance sake, but not for flying. Automobiles with transparent roofs, requiring occupants to bake to a well-seasoned brown under summer sun. More of the same.

But here and there were ideas which might click, and some which already have. Sketches of an integrated kitchen-and-bathroom unit attracted attention as a practical innovation. To be built as one piece and so installed, a wall was shown with kitchen sink and other accoutrements on its one side, and a bathroom lavatory, bowl and shower-and-tub on the other. The objective of such a combination is to reduce plumbing required for a home.

Also shown was a new idea in refrigerators, a low, wide, horizontal unit. Ice compartment, bottle storage and space for fast-frozen foods was provided on top, with lid opening. Underneath were sets of drawers for vegetables and miscellaneous storage, each opened by foot control bar at the base. One objective here was to reduce dissipation of refrigerated atmosphere by use of top lids and by comparatively small, individually-opened compartments. Another was to make possible varied temperatures.

Exhibited was a plywood chair by Ray Russell made by shaping one sheet of plywood to seat and back contour, then fastening it to a wooden base which sat on the floor.

Light metals and low pressure plastic molding were stressed in descriptions of the exhibits, and it is evident that recommendations for post-war product design will lean heavily in that direction.

Returning to automotive ideas, a number of interesting passenger car and bus designs were shown which represented logical advances on Packard Clipper, Lincoln-Zephyr and Lincoln Continental styling.

Tool and Die Group Plans Postwar Study

Washington

• • • **A program to prepare** the tool and die industry for orderly postwar conversion has been inaugurated by the National Tool & Die Manufacturers Association, according to M. W. Rowell, general manager. The program should be interesting to every industry in the country that is planning for postwar, Mr. Rowell pointed out, for even the large corporations with tool shops rely on the special tool and die industry for many tools, particularly those they are using for the first time.

As part of the program, a survey is being made of the tool and die industry's facilities and output in order to assist manufacturers in making an orderly transition to peacetime production. Reconversion to postwar production must take into consideration the special renegotiation problems of the industry, which consists of about 4000 small shops each employing from five to 60 men in normal times.

Usually, each shop is owned and managed by one or two people who, basically, are craftsmen risen through the ranks as tool and die makers. Unless they are permitted to emerge from the war with enough cash resources to operate over a period of comparative inactivity, bankruptcy and dislocation will result.

The program will also correlate new and revolutionary ideas developed in the past few years by tool and die plants working on war materials. There will also be an attempt through nine established "tool centers" to coordinate the work of the industry's local groups. These centers, already functioning, are located at Cleveland, Bridgeport, St. Louis, Rockford, New Britain, Buffalo, Minneapolis, Milwaukee and Chicago. Additional centers are being formed in other cities.

The Association was formed in September, 1943. Officers are: L. A. Sommer, Sommer & Adams Co., Cleveland, president; Richard F. Moore, Moore Special Tool Co., Inc., Bridgeport, first vice-president; Willis G. Ehrhardt, Ehrhardt Tool & Machine Co., St. Louis, second vice-president; Harry V. Anderson, Crescent Mfg. Co., secretary; and H. F. Jahn, B. Jahn Mfg. Co., New Britain, Conn., treasurer.

M. W. Rowell

Washington . . .

• Cartels hold Washington's attention . . . Proponents point to economic savings . . . Opponents argue it will be unworkable . . . Clearer understanding of what cartels are is needed

WASHINGTON—Is the United States moving into a long period of widespread cartelism? Many prominent business and government men think so.

One of the foremost business thinkers of the day, Eric Johnston, president of the U. S. Chamber of Commerce, told THE IRON AGE that he does not believe cartels can long be the answer to domestic economic problems because of the inevitable postwar dispersion of industries. Mr. Johnston pointed out that Russia plans to increase its steel capacity many fold and China, Brazil, and many of the British dominions expect to gain independence from foreign steel sources.

Mr. Johnston's view is that cartels before the war were possible in steel, chemicals, and illumination because many countries had little or no steelmaking facilities and because a lack of patents and technical skills kept many nations from competing in the chemical and lighting field. Competition caused by industrial dispersion will result in a check on the cartel movement, which depends largely for its success upon monopoly, is a summation of the Chamber of Commerce president's opinion.

On the other side of the question is Dr. Louis Domeratzky, chief, the European Unit, Division of Regional Economy, Bureau of Foreign and Domestic Commerce. Mr. Domeratzky, who for at least two decades has been conceded to be this government's leading authority on cartels and international economics, says that political cooperation between the United States and Great Britain should be paralleled by economic cooperation.

The current widespread interest in cartels in business and government can be traced first to the opportuning of Britons who declare that competition between former allies after the war will be ruinous to all concerned. Secondly, the interest springs from agreement with the British government and industrial viewpoint by comparable American groups and the fact that the Department of Agriculture has entered into international commodity agreements on agricultural products, which are in essence cartels.

MOREOVER, Justice's Anti-Trust Division has focussed public attention on the malpractices of cartels, while all over official Washington from the halls of Congress to the steps of the State Department an undercover dispute on the merits of cartelism is raging.

Not too much understanding of what cartels are is shared by all those engaged in argument. There is nothing inherently evil or sinful about cartels as Assistant Attorney General Wendell Berge has implied, nor is abuse of privileges any more confined to cartels than it is to corporations or partnerships.

Cartels are merely forms of business organization somewhat like trade associations which set prices, rates of production, and distribution in foreign and domestic markets, pursuant to inter-company agreements. However, the anti-trust laws forbid most of the activities of cartels in this country.

The question is: Should the United States make the activities of cartels legal and enact legislation to regulate them? Are international cartels necessary to protect domestic markets, find outlets for surplus materials and manufactures, and to maintain employment at high levels?

PERHAPS the most lucid criticism of cartels in recent literature is contained in an issue of *The Economist*, an English publication. *The Economist* stated that the doctrine appears to be growing up, almost unawares, that British industry cannot hope to compete on an open basis with other countries, cannot increase its volume of exports except through such mechanical devices as the cartel.

Said the English publication: "It is curious doctrine and is maintained with utmost inconsistency against both low-wage and high-wage countries. Where we are not undercut by the low wages of the Japanese, so runs the argument, we are undercut by the high productivity of the Americans. That is pure defeatism.

"It would be just as true to argue that, with good management, we can out-compete any country in the world, the low-wage countries by the skilled use of complex machinery, and the high-wage countries by the cheaper cost at which our policy of importing food and raw materials enables us to sustain a high standard of living. The real trouble is that too few British businessmen are trying to compete."

The publication points out that to say that a firm has so increased its efficiency that it can sell at low prices is not to give praise for initiative

HELP SMALL BUSINESS: *Jesse Jones, Secretary of Commerce, told the House Banking and Currency Committee that small business men and returning veterans, those who are bearing the brunt of the war effort, should have preferential treatment in the purchase of surplus government materials in the postwar period.*

TOOLS WORK TWO EXTRA SHIFTS PER WEEK

SUNOCO
EMULSIFYING CUTTING OIL

increases tool life 35% . . . improves finish . . . at war plant

Machine tool men looking for ways to effect tool economies will find this case history valuable. It's about a plant producing armament parts, and how they increased tool life the equivalent of two extra 8-hour shifts in every 48-hour week.

Production was slowed because of trouble on machines using a competitive soluble cutting oil. Tool casualties ran high, finish of parts was inferior, emulsions showed a tendency toward rancidity.

Trouble stopped when they changed to Sunoco Emulsifying Cutting Oil upon the advice of a Sun Oil Engineer. Tool life increased 35% . . . finish was noticeably finer . . . rancidity stopped. And in addition, cutting oil costs were cut.

Now parts are speeded from the machines of this plant . . . and from hundreds of other plants that have found Sunoco Emulsifying Cutting Oil a spur to machine tool output. Sunoco's exceptional heat-absorbing quality and stability make it the answer for all metal cutting operations where a soluble oil is used.

For advice on cutting oil problems, write

SUN OIL COMPANY · Philadelphia 3, Pa.
Sun Oil Company, Ltd., Toronto, Canada

SUN INDUSTRIAL PRODUCTS *HELPING INDUSTRY HELP AMERICA*

and enterprise, but to criticise it for breaking the rules of "fair" trading and indulging in "the ultimate sin of cutthroat competition."

BRIEFLY, the chief arguments against international cartelism are that they lead to "high-profits and low turn-over," and would "stereotype the present pattern of trade for all time and prevent the buoyant development of new opportunities in which is the chief hope for rising world prosperity" through stifling competition.

Cartel or combine proponents assert that this form of business organization offers distinct advantages to industry, labor and stockholders.

They maintain that labor can benefit through the fact that diminished competition forces fewer industry units out of existence than open competition and thus workers jobs are made more secure. Increased efficiency, it is further argued, can make for higher wages in large units than in small ones and uniform wage contracts are a concomitant.

The international labor organization has given its approval to agriculture's venture into cartels, but USWA president Philip Murray recently told THE IRON AGE that he is against the cartel idea.

Additional arguments made by cartel proponents are: Combines are able to save money through diminishing the cost of selling. Distribution organizations and promotional departments are merged and decreased in personnel. The not-so-successful business methods of member companies are subjected to the searchlight of comparison with more successful ones and inefficient operations are improved.

EXPENSIVE cross hauling is prevented through distribution of orders to member concerns close to the consumer needing steel. A saving of expense and time is made through distributing orders according to the facilities of member concerns whereas a single company might have to alter setups to accommodate a particular order.

Proponents also say that with decreased competition, unwise credit extension is no temptation to a cartel and yet, with government backing, credit can be extended beyond the limits a private concern would be able to go. Although not so profitable as domestic sales, increased volume of foreign sales can keep production costs down.

Too Much, Too Late

"• • • It is already too late for anybody to hold any brief for the citizens in the higher-income brackets. They are doomed through the actions of a demagogic, socialistic, soak-the-rich policy of this spendthrift administration. The welfare of the people in the low-income brackets is what gives me grave concern, because they are being slowly led to slaughter by the same rope that was used to lead the people in the higher-income brackets, and they are certain to suffer the same fate."—Senator O'Daniel, Democrat of Texas.

o o o

Army Leaves Price Role for OPA

Washington

• • • **The War Department** is not contemplating use of its repricing power contained in the new tax bill on an industry basis, and will leave the job of the fixing of flat prices to OPA, Brig. Gen. Albert J. Browning said on Feb. 16.

Gen. Browning, director of the purchases division, told a press conference that no contractor who is fairly pricing his products need fear the pricing title of the tax bill, a power which the Secretary of War has had since the enactment of the Second War Powers Act in 1942.

Lieut. Gen. Brehon Somervell, who heads Army Service Forces, has issued a directive requiring all repeat and continuation orders to be placed at prices which can be exempted from renegotiation by June 1, pending discontinuance of the Renegotiation Act by the end of 1944.

As provided by the new tax bill, orders which are so "close priced" between now and June 1 can be exemption from renegotiation. The close pricing is to be complete by June 1, but contracts in force on that date not drawn under the new program will be subject to renegotiation.

Glen A. Lloyd, assistant director of Army Purchases Division, said the end of renegotiation will present some new aspects of the War Department pricing problem.

"We will have to effect a greater control of prices paid to subcontractors under prime contracts," he commented.

THE BULL OF THE WOODS — BY J. R. WILLIAMS

How can machine tools avenge this

Dunkerque in Arkansas?

This is no enemy propaganda. No "usually well-informed sources" or Berlin broadcasts tell this tale. This is real . . . this is here . . . and this is defeat.

Our own private *peacetime* Dunkerque — in Arkansas, in New York, in West Virginia or California — in countless American "homes" where millions of people are ill-housed, ill-clothed, and bodily and mentally ill-fed.

What part will machine tools play in turning this kind of defeat into victory? The *whole* part, if the men of industry have the vision and the freedom to plan ahead, and to carry out what they plan.

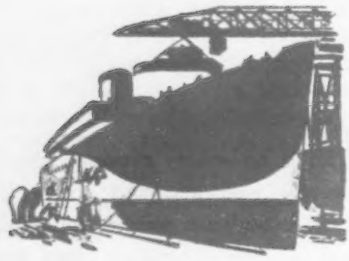
If you are a manufacturer, there is one thing you can do at once: Have your production men and planners consult now with the engineers of the leading basic machine tool producers. They can help you in planning today your part in the peace that must be won after the war is won.

One of these is a Bryant man. . . . We invite you to send for him.

BRYANT CHUCKING GRINDER COMPANY SPRINGFIELD VERMONT, U. S. A.

WEST COAST . . . OSGOOD MURDOCK

• Unusual owner-lessee relationship develops over Eagle Mountains ore deposit, most desirable for Fontana . . . Important Portland plant will not be rebuilt after fire.



LOS ANGELES—Following newspaper reports from Riverside headed "Kaiser Buys Solid Mountain of Iron Ore", when County Recorder Jack A. Ross filed a deed with $1100 revenue stamps on it, indicating a purchase price of approximately one million dollars for the Iron Chief Mine in the Eagle Mountains, the conflicting interests of the Southern Pacific Railway, the Riverside Iron & Steel Corp., Harlan H. Bradt and the Kaiser Co. Inc. have come to the front of the stage after long years in the wings and behind the backdrop.

War Minerals Report 97 of the Bureau of Mines dated February, 1943, describes in detail the 70,000,000 tons of potential ore reserves in this belt of metamorphic sedimentary rocks ¼ to 1¼ miles wide, extending over six miles across the northern part of the Eagle Mountains of northeastern Riverside County. The Iron Chief Mine is about 50 miles east of Indio on the line of the Los Angeles Metropolitan acqueduct and main power line from Boulder Dam and north of the Indio-Blythe highway. "It is one of the most important of the western iron ore regions and contains enough proved reserves to supply the iron and steel plants at Fontana for more than 20 years," declares the report. The magnetite-hematite ore averages a little over 50 per cent iron and 0.40 per cent sulphur.

After detailed exploration of the eastern part of the district, 1¼ out of 6½ miles of the range, the Bureau of Mines finds that "positive ore amounts to 21,629,000 tons averaging 51.2 per cent iron . . . probable ore in the same part of the district makes an additional 15,000,000 tons. From deposits explored, over $8,880,000 tons of ore averaging 53.9 iron and 0.11 per cent sulphur can be shipped directly to blast furnaces. Other ores can be beneficiated readily by either sintering or by gravity (sink-and-float) concentration, recovering 90 per cent of the iron in a product averaging 60 per cent iron and less than 0.20 per cent sulphur.

Harlan H. Bradt, president of the Riverside Iron & Steel Corp. who has been interested in this property for many years, his company holding a lease and purchase contract on it, declares that in addition to the 36,500,000 tons proven and probable in the eastern portion of the range, a sufficient additional amount of ore is geologically indicated in the 140 patented claims covering 2764 acres to bring the deposit well over 100,000,000 tons, over 80 per cent of the known ore in the southern California district.

To get the ore to Fontana it will be necessary to truck some 50 miles to the present railroad at Indio or to run a 50-mile spur from the S.P. main line at Mortmar near the Salton Sea.

The Riverside Iron & Steel Corp. entered into a lease and sale agreement April 24, 1940, which embodied an option period followed by a 10-year installment purchase agreement. This latter became effective Jan. 24, 1942, and specifies a final purchase price of $1,500,000 by the end of the ten years.

In its recent action, the Kaiser Co. has purchased for $1,000,000 from the Southern Pacific Land Co. its fee title to the ore subject to installment purchase contract with the Riverside Iron & Steel Corp. It is understood that the Kaiser Co. has borrowed additionally from RFC for the purchase.

Now that the lower grade and higher sulphur ore from its Vulcan mine is running low, the Fontana plant must soon have new ore. It is understood that sulphur in the present ore has run as high as 0.50.

It is further understood that Harlan Bradt offered to sell to the Kaiser interests rights to the Iron Chief ore at a low royalty in June, 1942, and later the Riverside Iron & Steel Corp. offered to deliver high grade beneficiated ore at a price acknowledged to be fair by representatives of RFC. The Riverside Iron & Steel Corp. is said to be backed financially by substantial interests in the mining and steel industry and in banking circles and expects to be able to carry its contract. Mr. Bradt proposes to erect a beneficiation plant at the mine to bring the ore up to 60 per cent bessemer grade with a guaranteed sulphur content below 0.20 or 0.10, whichever is demanded.

What kind of a deal will the Kaiser Co., as landlord, now make with the Riverside Iron & Steel Corp. its lessee?

IN spite of difficulties and handicaps with ore and coke and consequently pig-iron, the Kaiser-Fontana open hearths and rolling mill are reported to have performed remarkably. In January, 31,632 tons of plate were rolled and the high day was 1453 tons. For the first ten days in February the aggregate rolling was 11,283 tons. Furnace No. 1 produced a total of 10,917 tons of steel ingots in January and Furnace No. 5 10,913 tons. Until the structural mill is completed only four furnaces are now operated to supply the plate mill with ingots.

"What has happened to the Kaiser-Hughes flying boats" has frequently been asked of late and in answer Howard Hughes offers WPB a $500,000 guarantee that one of the giant plywood flying boats being hatched at Culver City will fly this year.

SEATTLE—For the fifth straight month Boeing has broken its production record, this time upping its production eight per cent over last month. This increase brings production up to over twice what it was just one year ago. In addition to the extensive in-plant feeding facilities being installed at the two Seattle plants, an expenditure of $2,500,000 has just been authorized for a new cafeteria building at the new Renton plant.

Washington state payrolls carried 886,850 workers at the start of this year compared with 607,672 just before Pearl Harbor. This shows an

Ex-Cell-O machine illustrated is an opposed Style 58 two-way machine arranged with six boring spindles at each end for finish boring, counterboring and facing the gear holes in an aluminum supercharger cover. All spindles operate simultaneously, finishing the holes within .0005" at a highly satisfactory production rate. The units have 20 inches of table travel and 15¾ inches between the ways. Each spindle is individually adjustable for quick setting. In this particular application all centers are set to a master gage, which, in effect, is a master for the part itself.

INCREASING PRODUCTION . . .

with new economy!

Ex-Cell-O Unit-type Precision Boring Machines Bring Added Practical Features

Ex-Cell-O has developed standard boring units, each a complete machine in itself, yet by means of heavy flanges and bolts these units can be bolted singly or in multiples to a stationary center section, resulting in a multiple precision boring machine. Note these advantages:

It is still a *precision* boring machine. Bores may be finished in tenths of thousands as before, yet units may be mounted in multiples and at angles, all operating simultaneously toward the center section.

Because all units may operate simultaneously, production is considerably increased on many parts.

The unit-type construction allows for salvage of all but the fixtures in case of part changes. It is possible and economical merely to remove and replace the entire center section. This means a flexible machine on which maximum production can be obtained while the machine is set up.

Each way or unit has two feeds and a dwell in forward and reverse direction, and each can be controlled individually or by a central control button in conjunction with all other units hooked into the electrical panel. It is completely automatic except for loading and unloading.

More than most semi-special machines, this Ex-Cell-O machine incorporates desirable features in flexibility and production, for war work today and peacetime products tomorrow.

EX-CELL-O CORPORATION • DETROIT 6, MICH

Ex-Cell-O has just printed a new folder on Unit-type and other Way Machines. A copy is yours for the asking. Send to Ex-Cell-O Corporation, Detroit 6, Michigan, and specify Bulletin 31631.

PRECISION THREAD GRINDING, BORING AND LAPPING MACHINES • SPECIAL MULTIPLE WAY-TYPE PRECISION BORING MACHINES • SPECIAL MULTIPLE PRECISION DRILLING MACHINES BROACHES • GRINDING SPINDLES • HYDRAULIC POWER UNITS • DRILL JIG BUSHINGS TOOL GRINDERS • CONTINENTAL CUTTING TOOLS • DIESEL FUEL INJECTION EQUIPMENT PURE-PAK CONTAINER MACHINES • R. R. PINS AND BUSHINGS • PRECISION PARTS

increase of 280,000 according to the report of A. F. Hardy, state manpower director. The ratio of women workers has increased from 21.3 per cent in the fall of 1940 to 35 per cent today. But railroads, trucking and communications employers have only 25 per cent more workers now than in 1940, threatening a crisis in communications if and when further demands occur.

A coastwide investigation of compliance with manpower regulations is in progress, successively in the Los Angeles, San Francisco and Seattle-Tacoma-Bremerton areas.

Strangely, in spite of USES and WMC pressure and pleas for more workers, claims for unemployment insurance are rising uncomfortably. In California there were 42,956 claims for benefits last September and 55,209 in December, an increase of 12,253.

A SERIOUS, sober setback to the industrial future of the Pacific Northwest occurred earlier in the month when the big Iron Fireman plant burned down mysteriously in Portland at night. This most costly fire in Portland's history destroyed 24 marine engines valued at nearly $100,000 each along with the foundry, forging, shop and assembly facilities which employed 1245 persons and during the war has been supplying propulsion machinery for Maritime ships.

Iron Fireman mechanical stokers were conceived and first developed at Portland, originally to use the sawdust so readily available from northwest lumber mills. As the company's market became nationwide, an eastern plant was established at Cleveland. The management now declares that the fire-destroyed Portland plant will not be rebuilt, since it is impossible to supply this national market from a Pacific Coast plant, and since in this case a second plant is not economically justified. Similar industrial experience moved Caterpillar and Le Tourneau from San Leandro and Stockton, California, to Peoria, Illinois, in the 20's.

Those fervid advocates of home industry and industrial destiny emanating from the Pacific Coast may well study carefully the factors and circumstances here involved.

o o o

Bearings Placed under Stricter WPB Controls

Washington

• • • **To further speed** the output of large size ball bearings, essential components for such war goods as heavy artillery and airport construction machinery, additional production controls have been announced by WPB. The new WPB order is expected to concentrate factory runs of large anti-friction bearings (ball bearings) and therefore make them available at a more rapid rate. Under the new WPB limitation order it is provided that:

1—Only manufacturers designated as "authorized producers" may make anti-friction bearings in specified large sizes.

2—A maker not designated as an "authorized producer" of bearing sizes listed in the order may refer potential customers for those sizes to an authorized producer or may accept the business and place the production contract with an authorized producer.

3—Any factory that might previously have made some bearings of the specified sizes but is not now designated as an authorized producer must keep its equipment for making such goods, and in such condition that it may be utilized within one month if so ordered by WPB.

Exceptions to the new anti-friction bearing order provide that:

1—Any orders placed before Feb. 19, 1943, may be completed even though the factory filling them is not listed as an "authorized producer."

2.—Producers whose monthly shipments of all anti-friction bearings did not exceed $60,000 in November, 1943, are not bound by the terms of the order.

Authorized producers for one or more of the specified bearing sizes are Marlin-Rockwell Corp., SKF Industries, Inc., Fafnir Bearing Co., and Torrington Co.

Steel Operations to Continue at Capacity

Washington

• • • **Steel Division Director** John T. Whiting said on Monday that the steel industry should operate close to capacity during the first half of the year, and that reports of an easier steel situation have created false impressions.

In a letter to all producers, Mr. Whiting said: "While it is true that cutbacks in programs have resulted in a slight reduction in the military requirements for steel, these have been offset by increases in the steel requirments for essential non-military needs. I refer particularly to the programs covering railroad equipment and track material, farm machinery, gas and oil facilities, food containers, etc.

"The net result has been an allotment of steel to the claimant agencies for the second quarter of 1944 approximately as great as that made for the first quarter."

Producers were urged to maintain maximum output and to observe all WPB orders and regulations.

Mining Equipment Reports

• • • **WPB announced** that mining equipment manufacturers need no longer file monthly reports on schedules for 40 items of equipment because production of these items is now meeting demand. This action was taken by amending Limitation order L-269. It provides, however, that manufacturers may be required to submit a report at any time, should such report be deemed necessary. In addition, the order provides that additional exemptions may be granted whenever it is justified by the supply-demand situation.

An amended list of all "mining equipment," giving CMP code numbers has been appended to the order, along with items for which no monthly reports are required.

. . . Cited for Awards . . .

• • • **The following companies** have won the Army-Navy E for excellence in war production:

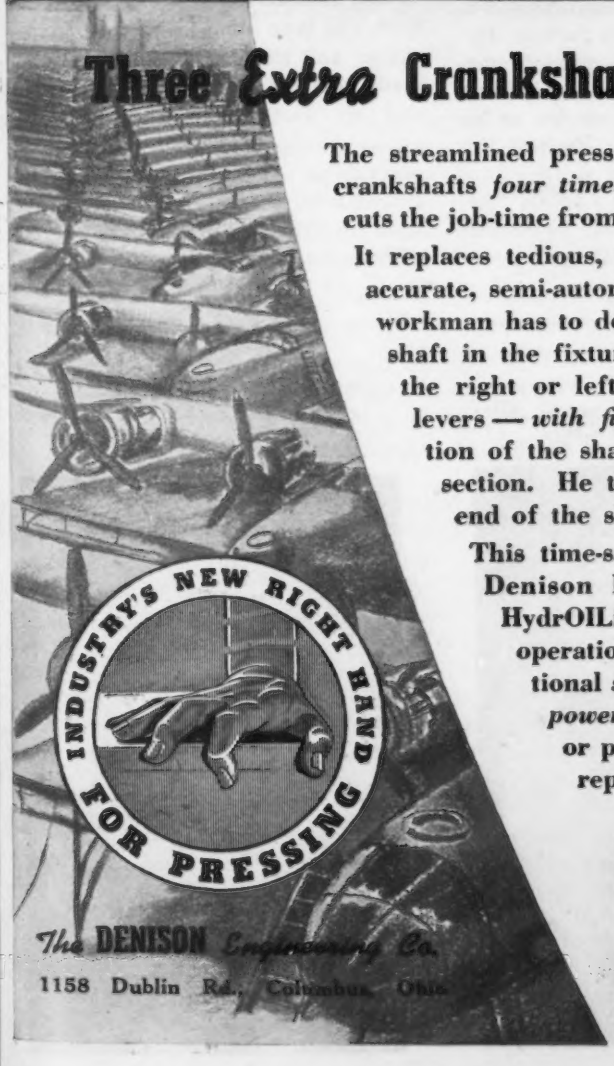
PRESSING NEW METHODS INTO SERVICE WITH INDUSTRY'S NEW RIGHT HAND



Three *Extra* Crankshafts Every Ten Minutes

The streamlined press shown above assembles airplane crankshafts *four times faster* than previous methods — cuts the job-time from *10* to 2½ minutes!

It replaces tedious, painstaking hand labor with quick, accurate, semi-automatic *oil hydraulic* operation. All the workman has to do now is lock the three sections of the shaft in the fixture, and direct hydraulic fluid to either the right or left ram. Then by moving ram-operating levers — *with fingertip pressure control* — one end section of the shaft is assembled to the rigidly held center section. He then repeats the operation on the opposite end of the shaft.

This time-saving equipment is a good example of how Denison Engineers are tailoring the advantages of HydrOILics to a constantly expanding field of industrial operations. They will be glad to show you how the exceptional *smoothness, flexibility and accuracy* of oil hydraulic *power, speed, and control* can be applied to your products or production. Write or wire today, or call your Denison representative.

TRADE-MARK

PERSONALS

• **W. P. Hilliard** has been named manager of the radio division of Bendix Aviation Corp., Baltimore, Md., and Red Bank, N. J. Mr. Hilliard, director of sales and engineering of the radio division since its inception in 1936, succeeds **Hugh Benet** who will assume other special assignments.

• **William Miller,** formerly Detroit district sales manager, has been appointed assistant general manager of sales of Jones & Laughlin Steel Corp., Pittsburgh. He has been with J & L for 30 years, serving in various sales capacities. **Charles M. Merritt,** formerly assistant Detroit district sales manager, will succeed Mr. Miller.

• **D. Trotter Jones,** former adjutant of the Alabama department, American Legion, has been elected executive vice-president of the Associated Industries of Alabama, Birmingham.

• **Myron M. Eicher** has been appointed works manager of Jessop Steel Co., Washington, Pa. He succeeded **Harry Wilson, Jr.,** who was promoted to vice-president in charge of operations. Mr. Eicher joined Jessop in 1942 as head of the scheduling department. Prior to that time, he was chief clerk in the scheduling division of the Crucible Steel Co. plant at Midland, Pa.

• **P. E. Floyd,** formerly sales manager of the Chicago district of the Allegheny Ludlum Steel Corp., has been appointed assistant general manager of sales for the corporation. Mr. Floyd will have his headquarters at Brackenridge, Pa.

• **A. P. Hall** has been appointed assistant general manager of sales of American Chain & Cable Co., Inc., Bridgeport, Conn., and will assume his duties March 1, with headquarters in New York. Mr. Hall has been with Bethlehem Steel Co. since 1922.

• **C. D. Williams** has been appointed vice-president and general counsel in charge of the corporate and legal affairs of American Locomotive Co., New York, and **Carl A. Sundberg,** formerly assistant treasurer, has been appointed secretary.

• **Russell M. Allen,** formerly general manager of sales, was elected vice-president in charge of sales of Allegheny Ludlum Steel Corp., Brackenridge, Pa. Mr. Allen became associated with Allegheny Steel Co. in 1920 as production man in the mill. In 1922 he entered the sales department, and in 1923 was transferred to the sales organization in Detroit. Two years later he became district manager of the Chicago territory, and was later recalled to Brackenridge as assistant sales manager. He held this position through the merger and formation of Allegheny Ludlum Steel Corp. in 1938, and in 1940 he became general manager of sales.

• **C. E. Kraehn** has been appointed assistant to V. H. Peterson, who is in charge of all sales activities of the Baldwin Locomotive Works, Philadelphia. Mr. Kraehn has been with Baldwin since 1943. Previously, he was with General Electric Co. for 24 years.

• **G. Bronson Philhower** has recently been added to the staff of the New York office of Tube Turns, Inc., to represent the firm in the New York area and New England.

• **Boyd R. Hopkins,** of Pasadena, has recently joined the sales department of the Thermex division of the Girdler Corp. and will represent the firm on the West coast.

• **W. S. Long,** formerly operations manager of United States Rubber Co.'s Los Angeles plant, has been appointed Pacific Coast sales manager, mechanical goods. Mr. Long will continue in charge of war products activities on the Pacific Coast.

• **George W. Hinds,** purchasing agent of the Lamson & Sessions Co. since 1926, has been named director of purchases and **Frank DeCrane** has been made purchasing agent. Mr. Hinds and Mr. DeCrane have worked together in the Lamson organization's purchasing department for 18 years, Mr. Hinds starting as purchasing agent in 1916, and Mr. DeCrane as an office boy in 1920.

P. E. FLOYD, assistant general manager of sales for Allegheny Ludlum Steel Corp.

RUSSELL M. ALLEN, vice-president in charge of sales, Allegheny Ludlum Steel Corp.

GEORGE W. HINDS, director of purchases, Lamson & Sessions Co.

W. H. HOLCOMB and JAMES J. NELSON, left to right, have been appointed vice-president in charge of industrial relations and vice-president of the Cramp Brass & Iron Foundries division of Baldwin Locomotive Works.

• **W. H. Holcomb,** assistant to the president of Baldwin Locomotive Works, Philadelphia, has been appointed vice-president in charge of industrial relations, a newly created office. **James J. Nelson,** general manager of the Cramp Brass & Iron foundries division of the company, has been named vice-president of the division. Mr. Holcomb entered the employ of the company in 1919. Mr. Nelson joined the Cramp Brass & Iron Foundries Co. in 1932 as vice-president and sales manager.

• **N. A. Holmer** has been appointed director of sales and marketing of the Elastic Stop Nut Corp., of America, Newark, N. J. In this capacity he will have charge of all marketing developments and sales planning for the company's patented stop nuts. Mr. Holmer was formerly general sales manager for Mid-States Steel & Wire Co., Crawfordsville, Ind., and before that was general sales manager for the Unity Mills Distributing Co., Minneapolis.

• **J. Richard Adams,** works manager of the Crucible Steel Casting Co., Lansdowne, Pa., has been elected vice-president of the company, in charge of operations.

• **Dwight R. Means,** who has been associated with the Columbia Chemical division of the Pittsburgh Plate Glass Co. for 21 years, has been named assistant to the vice-president. Prior to his new appointment he was technical director and had previously served as research director and assistant superintendent.

OBITUARY...

• **Benjamin F. Affleck,** who rose from an obscure office position to president of the Universal Atlas Cement Co. from which he retired in 1936, died suddenly of a heart attack on Feb. 13, in Winnetka, Ill. He was 74 years old.

• **Melvin V. Pattison,** chairman of the board and former president of Industrial Brownhoist Co., Bay City, Mich., died Feb. 11 after a long illness.

• **Guy E. Swartz,** president of Swartz Tool Products Co., Detroit, which he established in 1918, died recently.

• **John A. Camm,** 64 years of age, president of the Camm Blades Machinery Co., Milwaukee, died at his home there Feb. 4 after a long illness. He was previously head of the Cleveland Milling Machinery Co. and past president of the Western Iron Stores.

• **Charles F. Niemann,** born Feb., 1869, died at his home in Pittsburgh, Feb. 4, 1944, after a brief illness. He was president and treasurer of the Parkersburg Iron & Steel Co. of Parkersburg, W. Va., since 1906, and lived in that city for a number of years.

• **Robert W. Roloff,** formerly manufacturing manager of the Sylvania Electric Products, Inc., died Feb. 8 in Missouri. He was 64 years old and retired in 1939.

• **Elmer H. Boyer,** a General Electric Co., Lynn, Mass., executive for more than 40 years died Feb. 9, at Fairfield, Conn. He was born in Sunbury, Pa., 83 years ago, and was graduated from Lehigh University.

• **Charles E. Hahn,** general manager of the Cincinnati Electrical Tool Co., died at his home in Cincinnati recently. Mr. Hahn was 53 years old at the time of his death. He had been general manager of the Tool Company for the past eight years.

• **George L. Dumbauld,** vice-president and treasurer of Blaw-Knox Co., Pittsburgh, died Feb. 3 at his home in Glenshaw, Pa. He was 61 years old. Mr. Dumbauld joined the Blaw-Knox Co. as comptroller in 1920. In August, 1936, he was elected vice-president and treasurer.

• **Herbert W. Hunt,** a salesman for Braman Dow Co., Boston, for some 25 years and later a manufacturer of brass and copper pipe, died in Reading, Mass., Feb. 11. He was born in Somerville, Mass., 68 years ago.

• **William H. Foster,** one of the founders of the Foster Machine Co., Elkhart, Ind., died on Feb. 8 at the age of 73. In 1902 he founded the Foster-Kimball Machine Co., which later became known as the Foster Machine Co. Mr. Foster remained president of his company until the controlling interest was sold to the International Machine Tool Corp. (now the International Detrola Corp.) in 1939, at which time he became chairman of the board of directors. He retired soon after owing to failing health, but was retained in an advisory capacity up to the time of his death.

• **George L. Sargent,** retired president of Sargent & Co., hardware manufacturers, died Feb. 5. He was 81 years old.

• **Gus Anderson,** superintendent of the Louis Marx Co. Inc. of Pa. die shop at Erie, Pa., for over 20 years, died Jan. 30. He was 70 years of age.

Fatigue Cracks . . . BY A. H. DIX

Visiting Royalty

• • • We recently warned you that an impostor who signs himself "B. E. Plummer" is traveling through the Southwest, soliciting payment for subscriptions for your favorite family journal, and offering false receipts bearing the name of "Consolidated Trade Journals," a fictitious organization.

"Plummer," the National Publishers Assn. informs us, is the favorite alias of the famous Ray Palmer, the greatest figure his profession has ever produced, and as outstanding in his line as Henie, Tilden, Sande, Einstein, and Hoppe are in theirs.

His is no faint heart, to be turned aside from his mission by a jail sentence. Like the Greek whose strength multiplied with every knockdown, Palmer uses his periodic rests behind bars to improve his technique. It is said that he could sell a subscription for the *Catholic News* to a hardshell Baptist.

If he calls on you, the chances are he will be using the alias "Plummer," if it doesn't happen to be the week for that name to go to the cleaners. But under any name he is sharp-featured, reddish blonde, big-nosed, and if he visits you will you wire us collect, "PALMER HERE," as he is over-working himself and needs another rest.

Wrong Rockaway

You said that Dewey Pott is Rockaway, N. J.'s chief of police. Wrong. Our chief is Alfred Rarick. Dewey Pott belongs to Rockaway Valley, N. J.

—Edward Ehlers, President, Rockaway Rolling Mill, Rockaway, N. J.

"I" for An "E"

I am intrigued by the word "omniligent" used by you recently. It is new to me. I fail to find it in the unabridged. Apparently it is also new to Webster.

—Edward C. Worden, II, E. I. du Pont de Nemours & Co., Wilmington, Del.

"Omniligent" is an accidental and unhappy invention of ours, caused by our failure to copy "omnilegent" (meaning "reading everything") correctly from our drugstore dictionary. We had left our glasses in our other suit.

Miss—Or Hit!

• • • But the brains department is either blessed with two pairs of glasses or has only one suit, as this reveals:

Your Feb. 3 editorial ends "It will have been, as the saying goes, 'spurlos versank.'" Did your "Dutchman" join the army? It should be *versenkt*.

—I. Maddaus

All that is left us of a year's losing battle with the master race's tongue is "Ich weiss nicht was soll es bedeuten." *But our money is on versank.* This is hardly more than a hunch, reinforced by the fact that page 67 of the "German Grammar for Chemists and Other Science Students" reads, "To form the past indicative tense, endings are added to the past stem of the strong (irregular) verb, except in the first and third persons singular."

True Story

• • • Our Philadelphia G-2 reports that an old gentleman walked down the long steps of the Union League Club, stopped in front of a high-priced haberdasher's on Walnut St., stared at a $100 hand-painted necktie in the window, and muttered "Damn Roosevelt."

Boil It Down

I have been making inquiries about reading habits, and am not sure that the desire for brief copy will depart after the war.

So writes one of the brains department's outposts. One of the few things we are sure of is that love for brevity will not be a victim of peace. It did not come with the war and will not leave with the war. It predated the chisel and stone tablet age, and there is no evidence that fondness for the-whole-story-in-a-sentence is greater in these days than in Shakespeare's.

But the journalist who assumes that his customers want everything in tabloid form will soon have no customers. The customer is content with a news pill where the development is of little interest to him. But if it is something of vital concern to him he wants a report in extenso.

The *New York Times*, which tells all, is not only the country's most influential newspaper, but a top money-maker as well. You can feed a man a well-balanced diet of concentrates. In theory he is well-nourished, but the trouble is that before long he gets too weak to walk.

Pale Gray Matter

• • • People who try to live entirely on tabloids get pernicious mental anemia. They get to know next to nothing about everything and come to a sorrowful end. To protect you from this fate, your favorite family journal gives you a balanced diet of tabloids and roast beef. For the former, see Newsfront (page 47), This Industrial Week (page 98), and Briefly Told (page 108).

See elsewhere in the issue for reports long enough to cover the subject. If two paragraphs will do it, two paragraphs you get. If it is an epocha! development, like continuous casting (page 48), requiring twenty pages, twenty pages you get.

Aptronym

The pastor of a Beverly Hills church is the Rev. Thomas Bellringer.

—E. J. Ehret, Farval Corp.

Happy Marriage

• • • Army Ordnance did a neat bit of word-telescoping in entitling a recent booklet "Metalurgency."

Emily Post's Office Guide

• • • Tom Campbell, your Pittsburgh leg man, was shown a list of typical questions asked the librarian of a large firm in Tom's parish. One was, "What is the correct procedure in introducing a vice-president and a typist?"

Considering the relative supply of each, we think the first thing for the introducer to do is to set the vice-president at ease. We suggest, "Miss Hockenlooper, allow me to present our Mr. Drane. We hope you find him satisfactory. If not, don't hesitate to report him to the personnel director." At this point the vice-president steps forward, curtseys, and says, "Just call me Joe."

Stopper

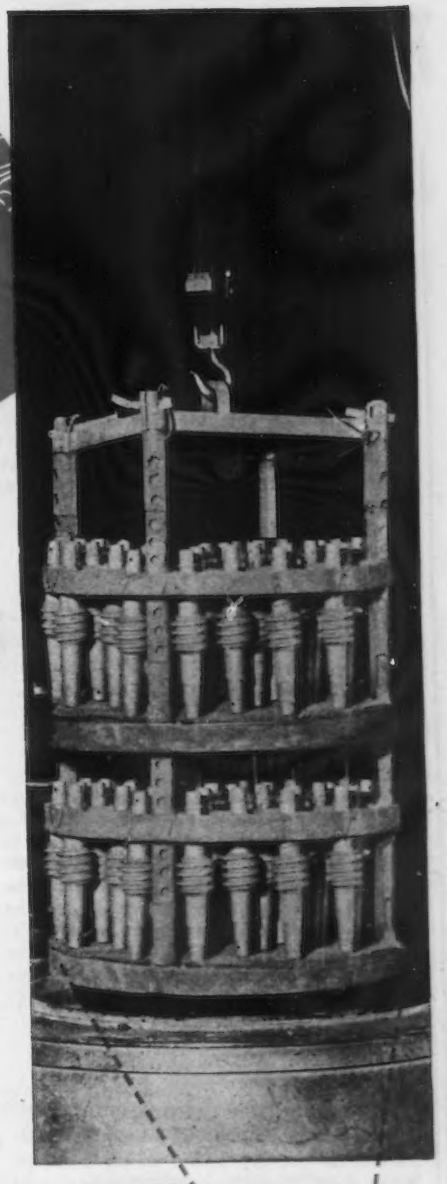
Puzzles

Last week's metallurgist was able to identify nine cubes, not counting a cube with no side ground. There were: 1 with 1 side ground, 2 with 2 sides ground, 2 with 3; and 1 with 1 side not ground, 2 with 2 not ground, and 1 with all sides ground.

Stan ("Assembly Line," see page 80) Brams sends this in:

This arrangement of 3 nines equals 11: $\frac{99}{9}$. *Rearrange them with simple mathematical signs to make them equal 80.*



Saves this labor and space and TRIPLES production

Lindberg Super Cyclone Furnace

ONE TYPICAL user by handling 100 worm gears per load, *increased production 3 times.*

This great improvement is possible because the work is confined in a small area and the heat is driven through the load at high velocity. Then the entire load is quenched at once, without piece-by-piece handling.

These are advantages of the principle of heating solely with fan-driven hot air which, in the Super-Cyclone, builds up temperature with rapid uniformity to as much as 1750°F. *throughout the charge.* Other advantages include keeping work straighter because there is no one-sided heat to cause distortion. Each piece and the complete mass of each piece is heated at the same rate.

And the versatile Super-Cyclone can be used for normalizing, hardening and tempering, with a temperature range from 300° to 1750°F. Lindberg furnaces can save for you too . . . write us now for complete information. Lindberg Engineering Company, 2452 W. Hubbard St., Chicago 12.

LINDBERG FURNACES

ARMY NAVY

SUPER-CYCLONE for hardening, normalizing, annealing, tempering
CYCLONE for accurate, low-cost tempering and nitriding
HYDRYZING for scale-free and decarb-free hardening

Dear Editor:

SCRAP TO JAPAN

Sir:

How much scrap iron was exported to Japan for the ten year period prior to Pearl Harbor, and what are the closest estimates of Japan's scrap inventory?

FULTON OURSLER
WOR,
New York

● An estimated 11,600,000 tons of scrap was exported from U. S. to Japan in the eleven years from Jan. 1, 1931, to Dec. 31, 1941. On Jan. 1, 1942, Japan had stocks estimated at 10,000,000 to 12,000,000 tons.—Ed.

BRAZED CAST IRON

Sir:

What are the anticipated strengths per lineal inch of brazed joint and the cross-sectional strength per square inch of cast iron brazed to steel?

OLIVER H. WATSON
Harold Van Doren & Associates,
1217 Madison Ave.,
Toledo

● Eutectic Welding Alloys Co., 40 Worth St., New York, makes a ferrous alloy (No. 14) that develops tensile strengths up to 48,000 lb. per sq. in. It is applied at 940 to 1400 deg. F., which is much below the melting point of cast iron or steel. The joint is color matching and machinable. Other copper-base alloys, which can be used in brazing cast iron and steel, give even higher strengths.—Ed.

JAP MAP

Sir:

We would like permission to reproduce the map of Japan's war plants in the April 30, 1942, issue of IRON AGE, for the use of army and navy officers attending our Civil Affairs Training School on the Far East. This school is an army military government school.

FRED EGGAN,
Director
University of Chicago

● Granted.—Ed.

NEW ALLOY STEEL

Sir:

One of my associates heard Mr. Joslin, of du Pont's, made a fine talk in which he pointed out that aluminum and magnesium play such a large part in the post-war metals field. He cited a new alloy steel with 19,000 lb. tensile strength which would weigh comparatively the same as aluminum for equal strength.

Can you give me the names of any of the steel companies we might write to for technicals on these steels?

H. A. BEHRENDT,
Secretary
Basic Advertising Organization
475 Fifth Ave.,
New York

● A cipher is missing. A tensile strength of 190,000 lb. per sq. in. is obviously meant, as this is about the upper limit for high tensile steels. One of the best discussions on possibilities of low allow high tensile steel is the article, "Is Steel a Laggard?" by Frederick D. Foote, in THE IRON AGE issue of Mar. 4, 1943.—Ed.

ETHYLCELLULOSE PLASTIC

Sir:

In a recent *News Front* you refer to ethylcellulose plastic. Where can we get this?

J. L. MAYER
Trimount Instrument Co.,
37 West Van Buren St.,
Chicago 5

● From the Japan Co., 5103 Lakeside, Cleveland. For more information on this material see the article in our Feb. 3 issue, beginning on page 54.—Ed.

GRIND ANGLES

Sir:

Where can we obtain a tabulation of the recommended grind angles for all types of cutting tools? We are especially interested in how the angles should be adapted to the composition and hardness of the material to be cut, the cutting conditions, the finish desired, and the tool size.

R. K. WARREN,
Metallurgist
Crucible Steel Co. of America,
Sanderson Bros. Wks.,
Syracuse, N. Y.

● Most handbooks show tool shapes worked out by Taylor and presented by him before the ASME in 1906. Some sketchy data on tool shapes are in "Manual on Cutting of Metals" published by the ASME in 1939. The manual is now being revised and the new edition will contain much more specific information on recommended angles.

The best work has been done by manufacturers of non-ferrous metals. American Brass Co., Waterbury, Conn., last year produced an excellent manual on machining copper and copper-base alloys which recommends tool angles for all classes of cutting tools. The Aluminum Co. of America, Pittsburgh, Pa., revises from year to year its booklet on machining of aluminum, and The Dow Chemical Co., Midland, Mich., has produced similar data on the machining of magnesium.

The cemented carbide manufacturers and the makers of Stellite have issued much literature on recommended tool angles.—Ed.

IRON MINE DIRECTORY

Sir:

We have in years past depended considerably on the Lake Superior Iron Ore book published in Cleveland as a directory of the northern iron mines, but the last issue was 1938 and, of course, numerous changes have been made during the interim.

At the moment we do not seem to be aware of a good compendium of the northern iron mines, and wonder if you could assist us.

A. B. MOSELEY,
Asst. Sales Mgr.
MacWhyte Co.,
Kenosha, Wis.

● The Mines Register, published by Atlas Publishing Co., 133 W. 21st St., New York City, 742-pages, price $15, covers all metal mines. The last edition is dated 1942. Minnesota Mines Experimental Station, University of Minnesota, Minn., publishes a mining directory of Minnesota.—Ed.

AVERAGE EARNINGS

Sir:

We are interested in obtaining information which will enable us to establish a base year in an appeal for relief on Federal Excess profits tax rates.

Our business is that of metal working, which includes machining and forging of machine parts. Can you advise us where we may obtain information on the earnings for this particular field of business for the past ten or twelve years?

H. W. UMBERGER,
Treasurer
The Brenner Engineering Co., Inc.,
Myerstown, Pa.

● Try the Machinery and Allied Products Institute, 221 N. LaSalle St., Chicago.—Ed.

REX CORE BINDER

Sir:

In a recent issue you referred to Rex core binder. Who makes it?

F. X. KINDBERG
Letz Mfg. Co.,
Crown Point, Ind.

● Rex core binder is distributed through F. B. Stevens Co., Inc., 500 3rd Street, Detroit.—Ed.

GAS CLEANING

Sir:

Can you let us have any information with regard to the question of cleaning blast furnace gases?

J. H. STOREY,
Managing Director
Darwen & Mostyn Iron Co., Ltd.,
Mostyn, Flintshire,
England

● We recommend the recent paper on the use of super-imposed precipitators in the cleaning of blast furnace gases, which was presented by B. B. Frost before the Association of Iron and Steel Engineers, 1010 Empire Bldg., Pittsburgh, Pa. We are asking the Association to send you a copy.—Ed.

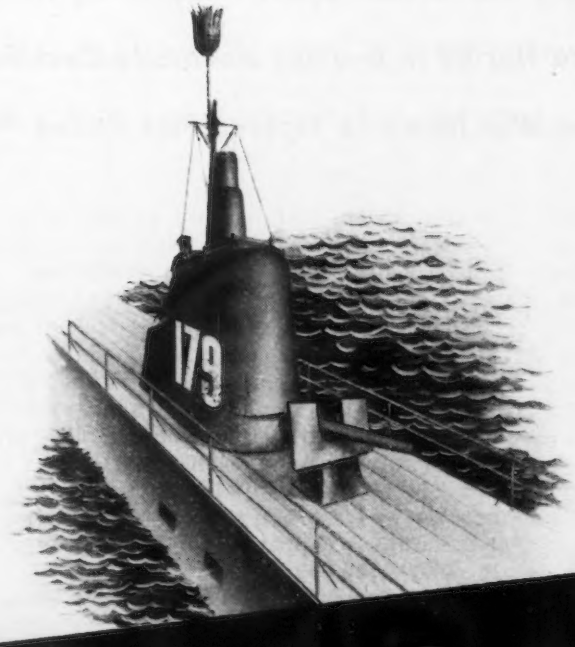
CENTRIFUGAL CASTINGS

Sir:

Thank you for the mention of our company on your "Dear Editor" page of Jan. 27. You intimated that we produce centrifugal castings. We do not operate a foundry of any type and are engaged solely in the manufacture of centrifugal casting machines.

However, the writer does do some actual centrifugal casting work, inasmuch as he is Consulting Engineer on centrifugal casting to the American Brake Shoe Co., and to the American Steel Foundries. He also does consulting work for other concerns on occasion.

NATHAN JANCO
Centrifugal Casting Machine Co.,
P. O. Box 947,
Tulsa, Okla.



Clean Sweep

When a Navy submarine comes into the home port with an old broom tied to the conning tower that is the sign of a "clean sweep." To a Navy man this means that every torpedo fired registered a hit. In metal cleaning, Wheelabrator makes a "clean sweep" in more than 2,000 plants on practically every conceivable cleaning application.

The Wheelabrator method of airless abrasive blasting registers a hit with every efficient business man as it knocks his cleaning problems into bits. Wheelabrating gives you these advantages: High-speed cleaning . . . Low-cost cleaning . . . Reduces horsepower . . . Conserves space . . . Reduces breakage . . . Speeds up machining and grinding . . . Lengthens tool life . . . Simplifies inspection . . . Improves appearance . . . Provides perfect bond for final finishing.

Check the list at the right and see how the Wheelabrator makes a "clean sweep" with cleaning problems for a variety of products.

Whatever your problems are, bring them to us. Our engineering staff has a wealth of sound experience that is ready to serve you.

This Industrial Week . . .

- ***Many Phases of Baruch's Masterful Report Favored by Industrialists***
- ***Nation's Railroads Face Hurdle in Getting Necessity Certificates***
- ***Use of Steel for Packing War Items to Tighten Flat Rolled Picture***

MOBILIZATION for war gave the United States some valuable but hard earned instruction emphasizing the need for speediness, coordination and practicality. Can these lessons be applied in the difficult demobilization era ahead? The Baruch Report, issued Feb. 18, puts the spotlight on this broad question, points out that a businesslike job is entirely feasible, and delineates a program of great scope proposing specific steps on the many key problems, including those of manpower, surplus materials and plants, contract termination, and reconversion. Moreover, reformation of certain governmental conditions and methods is advocated.

Industrialists concur heartily in such Baruch recommendations as those governing the expediting of tooling, avoidance of unneeded military surpluses, reduction of debt, gradual elimination of strictly wartime agencies, the encouragement of private enterprise, and the blasting of red tape.

The report, which is said to have the imprint of Presidential approval and to reflect some of the War Department's thinking tempered by Mr. Baruch's own ideas, has aroused a question in Congress as to protection of Congress' powers. Congress particularly seems to want to direct the reestablishment of veterans and demobilized civilians. From the viewpoint of the public the main thing desired is adequate insurance now against chaotic conditions in the event of sudden cessation of the war.

While insisting that the needs of war are paramount at this juncture, the report nevertheless reminds the War Department that the demands of a healthy economy cannot be retarded during war. This is a subject that has been debated hotly at intervals in Washington for many months.

CURRENTLY, the nation's railroads are facing a hurdle of getting certificates of necessity for the 1944 equipment program scheduled by ODT, because opposition has arisen in certain Washington quarters to amortizing all-steel freight cars under the five-year Treasury plan.

While WPB would like to see the production of nearly 19,000 freight cars in the third and fourth quarters, and has made material available to keep all capacity filled, railroad executives say they do not think more than 50,000 cars and 1000 locomotives will be made this year due to lack of manpower in shops. Only 9000 cars are scheduled now for production in third quarter, but orders for 13,000 additional have been placed, pending the decision on amortization. Orders for about 11,000 cars have been placed for first and second quarters.

The total metal allocation to ODT for second quarter was: Carbon steel, 1,490,000 tons; alloy steel, 105,900 tons; copper and copper products, 24,510,000 lb., and 5,756,000 lb. of aluminum.

Approximately 370,000 tons of steel were allocated in the second quarter for freight cars, 37,500 tons for locomotives, 550,000 tons for rails, 291,000 tons for track accessories, and about 80,000 tons for frogs and switches.

Recognizing the increasingly critical situation in automotive replacement parts, the WPB granted the entire ODT request of 137,000 tons of carbon steel for this purpose, a 47 per cent increase over the 93,000 tons granted for the first quarter. The military spare parts program, too, is larger this year, and constitutes a sizable share of all combat vehicle production today.

TWO widely heralded civilian goods ventures, the providing of more household irons and the experimental production of diversified goods by small plants in three areas, are lagging. Difficulty in proving non-interference with war work and difficulty in holding down to 1942 ceiling price levels are said to be a drag on the civilian iron project.

Steel production this week is still strong, the national ingot rate remaining at 96.5 per cent. In some quarters of the industry it is expected that the absolute necessity for making furnace repairs may be a slight drag on operations during the next few months. Labor for tearing down and rebuilding open hearths is scarce.

The tight situation in flat rolled steel appears likely to become even more hectic since a new Ordnance Department packaging program requiring large quantities of 12 to 14 gage sheet is imminent. Third quarter tin mill production is expected to exceed 800,000 tons, compared with an approach to 800,000 tons for the second quarter and slightly more than 600,000 tons in first quarter. Tubular goods mills are working at top speed against huge backlogs of orders.

AMONG current problems in the steel industry is the situation whereby to an increasing extent, molybdenum, nickel, and other alloys have been creeping into carbon steel heats where they are not

Steel Market Briefs

• GENERAL—Order volume will be high until outcome of European invasion becomes definitely known. Ingot stocking has diminished or disappeared. Repairs on furnaces may cause a two or three-point decline in the near future.

• FLAT ROLLED STEEL—Still tough. Plate directives heavy. No signs of let-up for some months. Carryovers at some plants are huge. Deep cutbacks have been made on barrel program, but still probability of later reinstatement of considerable tonnage. Sheet inquiries heavy. Deliveries are more extended. Change in the course of the war in Europe would drastically alter this picture.

• BARS—Backlogs on larger sizes heavier. Schedules well filled at some plants for first three months. Into August for some. Small sizes easier. Ammunition demands will support large bars for few months at least.

• TIN PLATE—Substantial tonnages of beer cans for export to be made in second quarter. Even more in third quarter. Third quarter tin mill production expected to exceed 800,000 tons, compared with an approach to 800,000 tons for the second quarter and slightly more than 600,000 tons to be produced this quarter.

• RAILS—Close to 2,200,000 tons expected to be produced this year. Second quarter stepped up from 515,000 to 550,000 tons. Return to mill on rail price portends upward adjustment by OPA.

• CANCELLATIONS—Increasing as a result of cutbacks, but continuing to be offset by heavy volume of new orders. Many cancellations turn into new orders at a later date, but trend is upward.

desired. Poor segregation of scrap and poorly meshed government orders are at the root of the troublesome problem, which is bothering certain mills more than others. Where possible, the heats with high residuals now are being diverted to such products as tie plates, spikes, fence and reinforcing bars, instead of going into vital uses where dies might be harmed and other damage caused. Steel producers have been urging customers to make wider use of triple alloy steels, but a $6 price differential is a barrier to wider acceptance of certain of these grades. Some customers recently have been pressing WPB to ease restrictions on SAE 2320, 3140 and 4140 steel.

So serious is the mixed carbon steel scrap problem that one steel company is sending a letter with every scrap order, specifying that carbon grades which contain in excess of 0.30 per cent nickel and 0.06 per cent moly will be rejected.

GETTING ready for hearings on the demand of the CIO-USWA for a 17c. per hour increase in wages, the War Labor Board has announced a panel of six which will consider the case. Meanwhile, WLB called a hearing for Wednesday of the present week on the question of extending contracts between USWA and 74 steel companies. They were cited to show cause why an interim order should not be issued extending contracts as requested by the union.

A further angle to the labor picture is a report that steel fabricators and miscellaneous manufacturers of steel products may be pressing to have their own WLB panel hearing, instead of being included with the companies actually producing iron and steel. Different competitive conditions would justify a separate hearing, it is held by the fabricators. The union naturally would oppose the move.

OPA'S study of carbon steel prices is proceeding as expected and it is now reported that findings will be released in two or three weeks, followed several weeks later by recommendations covering alloy steel. Meanwhile, the study into merchant iron ore prices which has been under way for a month is expected to result in a meeting of interested parties next Monday.

Congress Questions Broad Principle Involved in Baruch Report

By DONALD BROWNE
Washington Staff

o o o

• • • **Clearly bearing** the imprint of Presidential approval, Bernard M. Baruch issued a demobilization report last Friday which reminded the War Department that the demands of a healthy economy must not be retarded during the war, and warned WPB and industry and labor in general that the needs of war come before plans for reconversion, but that those plans must be formulated immediately.

Senator George, Democrat of Georgia, chairman of the Senate Postwar Committee, said that while most of the differences between the Baruch report and the report of his committee could be easily ironed out, the two reports are irreconcilable on the point of whether postwar economics should be governed by directive order or by general policies laid down by "the representatives of the people," meaning Congress. From Senator Murray, Democrat of Montana, chairman of Montana, came the comment that the Baruch report was "admirable" but that he was not prepared to endorse all of its principles. The Montana Senator added that the report "properly emphasizes" the need for broad legislative action by Congress.

One of the chief differences between the Baruch report and the recent George report is that the former opposes the creation of an Office of Demobilization which would have supreme authority over reconversion subject only to the direction by War Mobilizer Byrnes. The Senate committee would deprive the War Department of any authority over reconversion. The Baruch report would make the War Department an equal authority over reconversion with WPB.

The Baruch report which is strongly dominated by War Department thinking tempered by Mr. Baruch's own ideas holds out benefits to all classes of people.

Veterans and demobilized civilians are assured of a re-establishment of private enterprise, jobs through economic resurgence caused by a civilian goods boom and a government plan for distribution of war surpluses and peace production surpluses to foreign countries needing reconstruction.

To the civilian population is offered immediate introduction into retail channels of war surpluses which are needed by domestic economy. The general surplus plan is conditioned upon a three-fold method of disposition.

The plan is:

1—Sell during the war to state, local and foreign governments such goods which are perishable in nature or tend to early obsolescence; 2—ration over a period of time those goods of standard quality which are relatively durable; 3—scrap all war goods obsolescent in nature, or likely to remain unsold after strategic requirements are met.

Personal subsidies of credit during the adjustment period will be granted by the government to "those requiring it" and particularly for smaller business groups and returning service men.

Industry is told that it can resume peace production plans under an "X" day reconversion plan to be formulated now and put into effect as soon as the war in Europe ends. The War Department has geared its supply program to this hypothetical "X" day.

Speedy reconversion financing through government assistance and private guaranteed loans, and a termination plan which with minor exceptions agree with the bill introduced recently by Senators Murray and George are inducements to industry and labor.

In the same category is a suggested tax law to be enacted now and put "on-the-shelf" to reduce taxes from war to peace levels, "thereby providing necessary incentive for initiative and enterprise and stimulating employment.

Attached to all of the demobilization programs affecting labor, industry and returning servicemen are strings whereby controls can be maintained by War Mobilizer James F. Byrnes.

WPB is given many reconversion duties under the report. However, most of its authority is shared with the War Department, particularly in "X" day reconversion matters. Nothing is said about how soon limited civilian production can start above present levels.

Some of WPB's duties are:

Setting up policies for order of termination; determining the priority of civilian manufacture; allocating materials to war as well as reconverting industries; assisting in mak-

DETROIT DREAMS: *Industrial designers in the auto city are really letting their dreams take form. The gadget in the lower left is a lawnmower, but you will still have to walk in order to direct it. Too bad it wasn't equipped with the chair shown in the center picture.*

ing policy on termination and surpluses through membership in two new interdepartmental bodies which are to govern these activities; and making plans for general reconversion through industry advisory committees.

The usual administration slap at pressure groups is contained in the report which also recommends that wartime industrial controls be relaxed in an orderly fashion and as quickly as feasible. The report does not say, however, when this period of relaxation should end and government controls dropped.

The War Department is gently chided although praised for its "fine advance planning which is under way and civilian agencies are told to "organize themselves to use the information effectively." The chiding has to do with War Department policy on making known its shifts in production programs public.

"To assure that cancellations will be planned in advance as far as is practicable and to remedy the inadequacies we found, we are recommending this tightening up of the cancellation procedure:

"1. The procurement agencies, in acting on the decision of the Chiefs of Staff, to inform the WPB of possible cancellations a soon as they begin to think of them, this should be done so WPB and other civilian agencies can become properly attuned for swift action when decisions are made.

"**We recommend** that the OWI, WPB and the procurement agencies work out the necessary machinery for informing the public fully and frankly as to the problem involved and the actions taken."

In calling for "speediest resumption of civilian production" to control the inflationary gap and make for a smooth transition to peace through enabling government and industry to plan for "X" day, Mr. Baruch dealt with great sagacity with the War Department fears of "complacency" if civilian plans are made, or put into effect.

He said: "With the hardest and bloodiest fighting ahead, some will object to such planning, in the fear that talk of resuming civilian production will divert people from the war; and perhaps, even precipitate a scramble by some to get back into peacetime production. We have weighed this view most carefully. It is an argument not without basis. But we conclude that the American people will face the facts courageously if the Government deals frankly with them.

"An early or sudden collapse of the Nazis in Europe, finding us unprepared for handling the transition problem could result in such chaos and confusion as to seriously obstruct the most effective prosecution of the war against Japan, and the last few weeks have given every American a special reason for not wanting to lose a minute in getting on with that job.

"Plan for peace? Yes. Let up on war? No."

TERMINATIONS — Termination features of the plan include: To assure quick cash pending settlement, immediate payment in full for completed and uncompleted contracts to prime and sub-contractors; payment of interest in termination claims; loans by local banks to war contractors to assure against delays in claim validating; direct government loans if banks aren't able to handle loans in 30 days; quick, fair, and final settlement through negotiation by contractors and procurement agencies.

Review powers of Controller General limited to fraud; settlements made by team of negotiators; teams filing reports and keeping records; contractors to keep records for three years; additions of Controller General and Attorney General to Joint Contract Termination Board.

Establishment of Joint Contract Termination Board within OWM to unify procedures and policies of all agencies. Chairman of this board to report to Congress, maintain surveys of V, VT, and T loans; recommend changes in contract settlement.

Spread acceptance by war contractors of uniform termination article for fixed price contracts.

Speedy handling of subcontractor claims. Prompt clearance of government property from private plants.

SURPLUS PROPERTY — Surplus property features of the plan include:

(CONTINUED ON PAGE 104)

WLB Steel Wage Panel

• • • The War Labor Board announced the names of the members who will form the panel to take evidence in the wage dispute between the USWA-CIO and the steel industry. Hearings will begin soon on procedure, which will be reported to the WLB before the panel takes evidence on the merits of the case. The panel members are:

Public—David L. Cole, chairman, public member of the Second Regional-WLB in New York and chairman of the New Jersey State Board of Mediation, and N. P. Feinsinger, vice chairman, director of the WLB disputes division and until recently chairman of the WLB trucking commission.

Industry — Hugh Morrow, president of the Sloss-Sheffield Steel and Iron Co., Birmingham, Ala., and Edwin D. Bransome, president of the Vanadium Corp. of America.

Labor—John Despol of San Francisco, international representative of the USWA on the Pacific Coast, and Stephen Levitzky of Pittsburgh, a charter member and international representative of the USWA.

SUPREME COMMAND: ***Meeting in London on Feb. 1, to plan second front operations were: (seated, left to right) Air Chief Marshal Sir Arthur Tedder, Deputy Supreme Commander; Gen. Dwight D. Eisenhower, Supreme Commander; Gen. Sir Bernard L. Montgomery, Commander British Land Armies. Standing (left to right) Lt. Gen. Omar N. Bradley, Commander American Ground Forces; Admiral Sir Bertram Ramsey, Naval Commander in Chief; Air Chief Marshal Trafford L. Leigh-Mallory, Air Commander in Chief; and Lt. Gen. Walter B. Smith, Chief of Staff.***

Eighty-One Years of Steel Production in the United States

• The following tabulation is the production of steel ingots and castings compiled by the American Iron and Steel Institute. After 1933 the figures include only steel castings produced by companies making steel ingots. The chart is appearing in "Steel Facts," published by the Institute.

Years	Net Tons
1863	9,044
1864	10,369
1865	15,262
1866	18,973
1867	22,000
1868	30,000
1869	35,000
1870	77,000
1871	82,000
1872	160,108

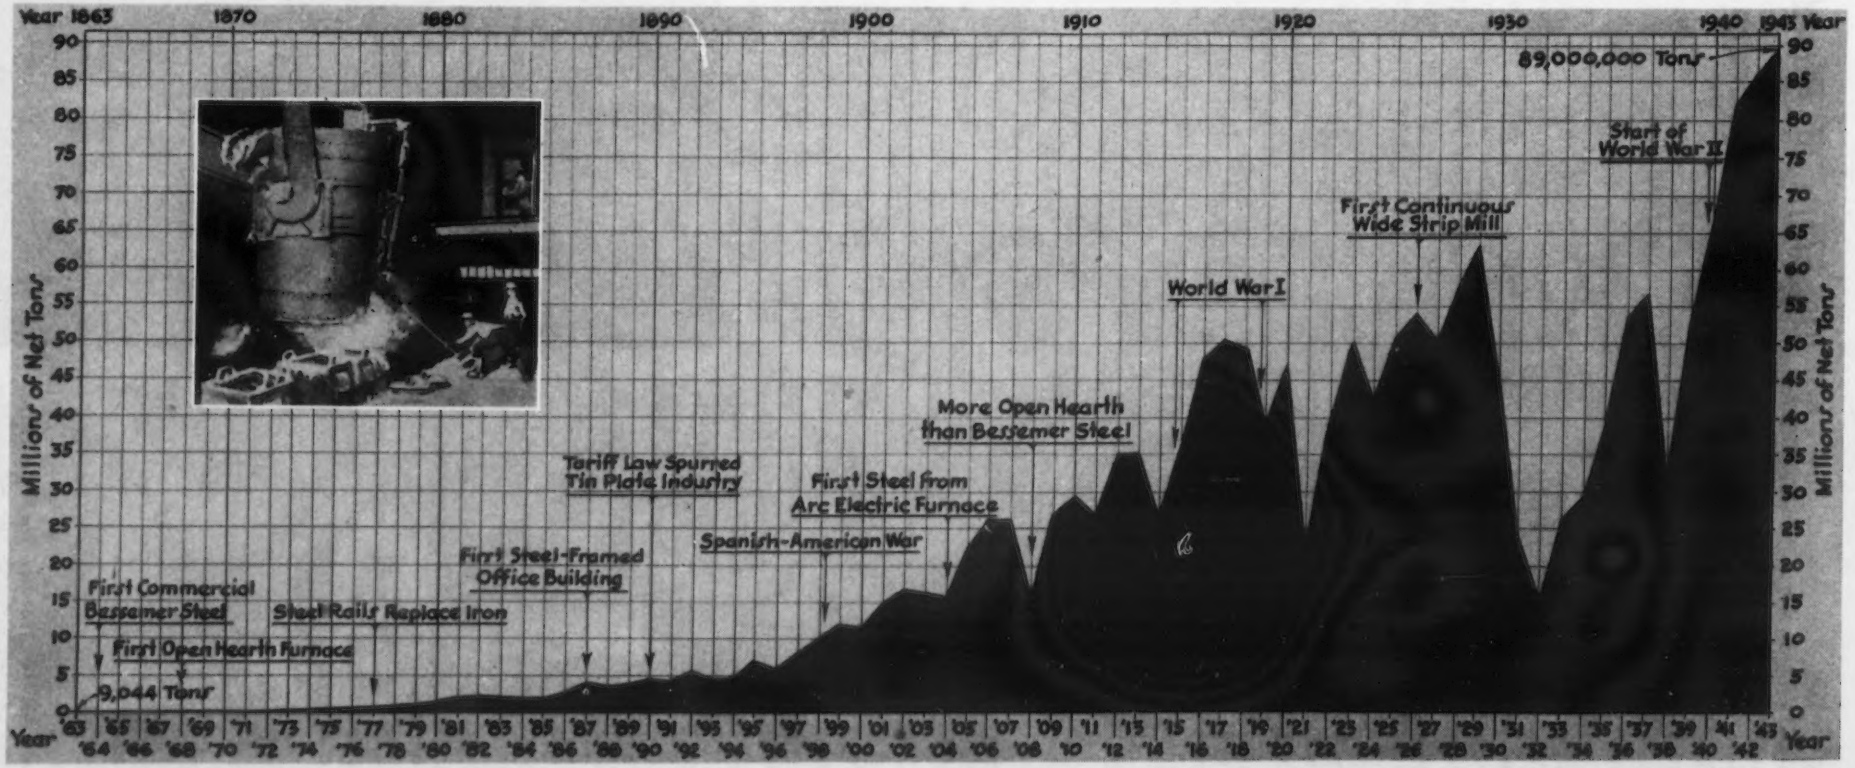
1941	82,839,259
1942	86,031,931
1943	88,872,598*

* Preliminary.



The OWM director shall name a Surplus Property Administrator with full authority to handle all surplus disposal. A Surplus Property Policy Board shall be created with various government agencies represented.

Four major outlets are planned to handle actual disposal, each in a clearly defined field, with no overlapping: Consumer goods to the Treasury Procurement Division. Capital and producer goods, to a single corporation within RFC, consolidating present RFC subsidiaries. Ships and maritime property to the Maritime Commission.

The Surplus Administrator to report to Congress on legislation needed, basing recommendations on actual experience with the problem.

Suggestions by Baruch as to the broad policies that the Surplus Administrator may wish to follow are summed up in 10 basic principles.

All disposal agencies are to make effective use of Industry Advisory Committees. The Army and Navy are to examine inventories of critical civilian items to see what can be released during the war for the civilian economy.

RECONVERSION — Reconversion features of the plan include: Armed Services and WPB to work out an "X" Day reconversion plan based on the assumed defeat of Germany on a hypothetical "X" Day. Contract cancellation shall be integrated with procurement and expansion of civilian production so facilities and manpower are shifted to new war work. A full frank information policy shall be established on all cutbacks and cancellations.

The WPB shall work out in advance policies on which producers should be canceled and which left in production. The choices are to be made after consultation with WMC and other interested agencies.

Protection of small business in the resumption of civilian production as far as practicable without interfering with the war is urged.

Advance listing of the priorities are to be given different civilian needs in any opening up of civilian supply. The highest priority to go to those things which contribute directly or indirectly to improved military efficiency such as vital repairs, transportation.

As far as possible, all competitors to be treated alike in the resumption of civilian production.

Problem of Residuals in Carbon Steel Forces Producers to Take Definite Steps

By D. C. MacDONALD
Cleveland Regional Editor

o o o

• • • **The trend away** from the production of pure analysis carbon steel has been growing during the past few months as a by-product of poor scrap segregation. The impetus placed behind the government alloy scrap segregation order has apparently produced some results in that direction. But with little or no incentive to accurately segregate plain carbon grades, very little scrap moving to the mills today can be trusted as being uncontaminated by one or more alloys, several steel producers report.

Orders for plain carbon steel in one principle area for instance are reported being accepted on the basis that residual nickel will not exceed 0.20 per cent and moly not over 0.08 per cent. A cross check of recent heats from several melters here shows open hearth plain carbon melts running from 0.06 to 0.10 per cent nickel, 0.07 to 0.10 per cent copper, 0.08 to 0.10 per cent molybdenum and in some cases up to 0.10 per cent tin. One exceptionally bad heat reported ran 0.37 per cent nickel and another 0.26 per cent nickel.

Moly is considered to be the most troublesome residual especially when deep drawing qualities are required. Nickel has been proving exceptionally troublesome in free-cutting steels. Chromium, which oxidizes off in the open hearth, has caused no trouble but its waste in this manner is being pointed out.

Just what amount of alloy is going into the making of carbon steel is impossible to estimate. Every car of presumably plain carbon scrap going into the yards of most consumers today is now being analyzed and the mean analysis of the alloy content used as a guide in charging. Melters report that practically every carload has some contamination and a spot check of mean anlysis reports showed nickel running as high as 0.45 to 0.62 per cent in a number of instances indicating that the car probably had nickel scrap running as high as 1.25 or 1.50 per cent mixed in with plain carbon.

Since the analysis limits of plain carbon steel have in reality nearly taken on a new set of tolerances, melters are working with the contaminated scrap to produce "mild alloys" within a given tolerance to be marketed as plain carbon grades. No premiums or discounts enter into the sale and in all cases the steel goes into normal plain carbon uses. However, wherever possible it is diverted to such products as tie plates, spikes, fence, barbed wire, nails and reinforcing bars. The waste of vital alloys in this way is beginning to catch the attention of both industry and the government.

Some dilution of high alloy content scrap is also being achieved by melting turnings in the blast furnace and charging the open hearths with pig containing somewhat less alloy than the original scrap and then further diluting with pure carbon scrap.

The effects of the various residuals are being offset by balancing the analysis through adjusting the carbon and manganese contents. However, troubles with the steels are being reported and one producer has had to cease making certain grades in some furnaces due to the nature of his local scrap supply.

Industry Gives Returning Veterans A Helping Hand in Rehabilitation

Boston

• • • **Progress** is being made by Massachusetts industry in rehabilitation of veterans, especially by large concerns such as the Westinghouse Electric & Mfg. Co., and the General Electric Co. There has not been a single instance where a veteran returning to civilian life and applying for re-employment at the plant he left to enter the armed services has been turned down.

There have been cases, however, where a veteran is incapacitated for his original job, but in such instances he is put to work at some other task. Statistics regarding rehabilitation are not always available because the number of returning veterans is, in the case of some plants, not significant enough to be impressive. However, a very good idea of the progress of rehabilitation is had through the United States Employment Service in Boston. Some 800 war veterans are placed in civilian jobs each month by that organization.

The service reports that a very large majority of veterans want jobs in non-war plants, evidently figuring that postwar security is relatively more essential than high war job pay now. A great many veterans require a month or longer to get their civilian bearings and are strangely lacking in direction and purpose. The greatest handicap to rehabilitation is the many cases of psychoneurosis, the shock of rigorous basic army training making the veteran chronically morose.

Management knows that discontent and self-pity quickly rob producers of their efficiency, therefore it is important not to allow the handicapped man to grow to feel, because of his disability, that he is an object of charity, according to Robert M. Gaylord, president of the National Association of Manufacturers.

He believes that while a veteran is being trained to become self-sustaining it should be done in such a manner that his individuality develops, his earning power increases and his own dignity grows because of the work he is doing. He must realize that he will not be discriminated against because of his disabilities, but at the same time he must be able to produce effectively in competition with other men to keep a job at going rates.

Industry's responsibility for rehabilitation of all veterans who want to work and are able to receive training is vitally important and it is necessary that management take a personal interest in it before it becomes routine, according to Mr. Gaylord.

The average Massachusetts industry keeps in mind that to re-employ men now when plants are running full is one thing, and keeping them on the payroll is another. Manufacturers are therefore keeping before the public the kind of goods they make, and by so doing are laying the foundation for postwar business.

o o o

Steel Research Committee Will Develop Wage Fight Data

Pittsburgh

• • • **Steel companies and** the United Steel Workers of America are making initial preparations for what is believed will be a long, drawn-out, War Labor Board hearing on the CIO's request for a 17c. an hr. raise, shift differentials, guaranteed annual wage, sick leave, etc.

A Steel Case Research Committee, to work with individual iron and steel companies in their forthcoming hearings before the WLB, has been established, according to John A. Stevens, vice-president, industrial relations, U. S. Steel Corp. of Delaware, who is chairman of this committee. Other members are: J. C. Argetsinger, vice-president and general counsel, Youngstown Sheet & Tube Co.; R. Conrad Cooper, assistant vice-president, Wheeling Steel Corp., J. M. Larkin, vice-president, Bethlehem Steel Corp., and, Lauson Stone, president, Follansbee Steel Corp.

The committee will produce data and conduct research on steel industry facts and figures pertinent to the steel case.

The Steel Case Research Committee has retained M. K. Mellott and Co., Pittsburgh, as public relations counsel. Temporary offices of the committee are with the Mellott firm.

The United Steel Workers of America are now preparing their data for the hearing, and, it is believed, much of its argument for higher pay will be built around the cost of living study recently made public by the two labor members of the President's Cost of Living Survey Committee.

Speculative opinion on how much the steel union will obtain in the way of a wage increase, regardless of the method used to produce such an increase, ranges from seven to 10c. an hr.

WLB Holds Hearing

• • • The National War Labor Board scheduled a public hearing, Feb. 23, in the Department of Labor Building, Washington, on the question of extending the contracts between USWA-CIO, and 74 steel companies.

The union has moved to terminate its contracts with these companies in order to negotiate for wage increases and petitioned the Board to extend the contracts as the Board did in the case of 500 steel companies covered by a similar petition Dec. 27, 1943.

Secondary Warehouses Want Zone Price System

• • • **Warehouses are closely** watching the results of the study of steel production costs undertaken by the OPA in an effort to determine the need for ceiling price adjustments since any price adjustments on the mill level obviously will be reflected directly in warehouse costs.

However, as pointed out by the Steel Products Warehouse Association, Inc., Cleveland, an association covering the bulk of the secondary and resale warehouses, such cost adjustments will be automatically translated into adjustment in resale prices on prime materials only. On rejects and seconds, however, resale prices are fixed and will not move in relation to changes on the mill level.

Thus, if mill ceilings increase, the price paid by secondary and reject warehouses will go up but the selling price will remain fixed. To overcome this discrepancy, the association plans to recommend to OPA a zone price structure for secondary products, which would tie resale prices to mill prices. Specific proposals prepared by the Association are being submitted to OPA to provide a basis for the adoption of the prime price structure.

Plates About Half of Flat Rolled Output

Pittsburgh

• • • **Slightly more than** 48 per cent of the total flat rolled steel products produced for sale in 1943 consisted of plates. This compares with 17.3 per cent participation for plates in 1939. The trend, so far this year, is probably close to 50 per cent of flat rolled production, going into various types of plates, due to the continuation of the unprecedented shipbuilding program.

The phenomenal increase in plate production during 1942 and 1943, which materialized, for the most part, through the conversion of wide strip mills, was also supported by unprecedented production records on regular plate units. This gigantic output was necessarily at the expense of sheet and tin mill production.

The tables accompanying this story disclose the various trends in various flat rolled steel production. It is expected that the trend in plate production has reached its zenith, and will, by mid-year, start a slow downward trend, both in participation and in actual production. Likewise, the trend in sheet production, which has been downward because of plate requirements, will probably, in the third quarter of this year, make a slow start toward regaining its pre-war position. These opinions, however, are predicated entirely upon Allied successes in Europe by August of this year—successes which will show, beyond any reasonable doubt, that the defeat of Germany is practically an established fact. Unlooked for military reverses, in the European phase of the war, would, in all probability, hold down not only sheet and tin mill production, but would also keep plate output around present levels.

The loosening up, by the WPB, on tin mill restrictions, means, no doubt, that production of these items in 1944 will be somewhat ahead of 1943, when tin mill output constituted about 9 per cent of total flat rolled steel production, as contrasted with 17.4 per cent in 1939.

In comparing the position of total flat rolled steel output with respect to total finished steel produced for sale, it has maintained its relative importance fairly well since 1939. In that year, total flat rolled production was 46.5 per cent of total finished steel produced, as contrasted with 43 per cent in 1943. The decline in the participation of sheets, tin plate and strip, was almost entirely offset by the substantial increase in plate output.

As a pure guess, it seems possible that the position of flat rolled production and its various components, after the end of the European phase of the war, will probably take a pattern somewhat along the line shown in the statistics below for 1941. At the close of all military hostilities, it seems reasonable to believe that the 1939 pattern will predominate.

Lukens Earns $1,317,280

Coatesville, Pa.

• • • **After all charges** including $4,320,000, for Federal and state taxes on income and a postwar reserve of $733,000, for the 1943 fiscal year which ended Oct. 9, Lukens Steel Co. reported a net income of $1,317,280. This compares with $1,172,522 earned in the 1942 fiscal period after provisions of $3,900,000 for taxes, $330,000 for postwar reserves, and $2,500,000 for renegotiation of contracts.

Manufacturing costs of products sold during the year were 19.5 per cent higher than in 1942, while sales were 13 per cent higher than during 1942. The company purchased $634,000 of its 4.75 per cent sinking fund debentures during the year, of which $298,000 were retired through the operation of the sinking fund and $336,000 are held in the treasury. On Oct. 9, 1943, $1,556,000 of the debentures were outstanding in the hands of the public, which compares with $2,200,000 on Oct. 10, 1942.

Engine Cylinder Life Extended By New Chromium Plating Process

New York

• • • **Postwar motor car,** airplane, marine, and industrial engine cylinders may be expected to run from 4 to 20 times longer than thought possible before Pearl Harbor. Under military restrictions, the existence of a development that prolongs engine life to such an extent has remained practically unknown to the public. It has been used in the Navy's submarines since the beginning of the war, giving undersea craft longer striking ranges.

Of late, it has been adapted to reconditioning cylinders of planes. Tests show that the worn cylinder barrels can be renewed by this process and made capable of six times their original life. It is also being used to reclaim tank engines.

This development was brought to America by a Hollander, Hendrik Van der Horst. It involves coating cylinder walls with a thick layer of hard chromium applied by a special process that leaves the plated surface porous. The plating has high resistance both to wear and the corrosive acids that accumulate in engine combustion chambers.

The chromium is applied to cylinders in such a manner that the surfaces are made porous, like a sponge, to retain an even distribution of oil. Van der Horst, in interesting the Navy in the development, was given the salvaged engines of the ill-fated submarine squalus on which to apply what was aptly termed Porus-Krome. The success of that effort quickly led to further use of the process by the Navy before war broke out.

Recognizing acceptance of the process led to formation of the Van der Horst Corp. of America, which now operates plants in Olean, N. Y. and Cleveland. Under license from this concern, the process is applied to piston rings manufactured by American Hammered Piston Ring division of the Koppers Co., Baltimore; the Wilkening Piston Ring Co., Philadelphia, and the Kohler Co., Kohler, Wis.

In addition to being used in many of the combat vehicle engines, compressors and stationary diesels used by many plants engaged in the war effort are so equipped, and a number of tests and experimental installations are on record.

New York Omnibus Corp. reported that a group of its bus engines proved to have five times longer cylinder life as a result of using Porus-Krome. A tank truck and trailer of the fleet operated by the Willett Co., Chicago, has hauled 110,000 miles and shows only 0.002 in. of wear in its chromium processed cylinders.

These instances, and others now coming to attention in various industries, give promise of "more miles per dollar" from postwar use of this process.

o o o

Large Projects May Aid Bar Sellers

Pittsburgh

• • • **Although** the concrete bar industry is still being pushed around, tonnage-wise (its order volume being only about a third of normal practice) there seems to be some glimmer of hope on the horizon when postwar construction, or even pre-postwar building, finally is permitted.

At a recent meeting, covering construction subjects, some members of Congress hazarded guesses that close to $3,000,000,000 of Federal funds, probably will go for road building after the war. These Congressional sources, however, suggested that State and County personnel do not wait until the war is over to make their plans.

Another angle, which has entered into the discussion of preparing for postwar or pre-postwar construction, is the need for supplying jobs to men who are constantly being released from military service. A rough estimate, given recently, indicated that about 100,000 men a month were being released from the armed forces.

Briefly Told—

Reserves and Renegotiation
Alabama Detinning Plant
Mystic Banks Furnace

• Representing the six Government renegotiating agencies the Joint Price Adjustment Board held that reserves for war contract renegotiation funds which may be set aside are "not to be considered directly or indirectly" in connection with determinations of price adjustment refunds to the Government. Chairman Joseph M. Dodge said that the "increasing practice of providing such reserves is to be encouraged as a matter of sound accounting."

•

• *Affecting 25,000 workers, a liberalized vacation plan for hourly rated employees, allowing a week's vacation with pay for those with one year's service, has been approved by the War Labor Board for the Aluminum Co. of America. The previous vacation system allowed vacation pay only for those with at least two years of service. Employees with five years of service will get two weeks' vacation with pay as heretofore. If time off cannot be taken, the employee will be given vacation pay in lieu of time off.*

•

• The new detinning plant at Birmingham, Ala., financed by the Defense Plant Corp., went into operation Feb. 15. The plant is being supplied with salvaged tin cans from Alabama, Georgia, Florida, Mississippi, and other states with easy rail connections. This was the only complete DPC-built detinning plant project that was finished. Some 25 or 26 other such projects were cancelled before completion. The Birmingham plant was built by H. K. Ferguson Co., Cleveland.

•

• *The Mystic Iron Works has decided to temporarily bank its furnace Feb. 20. In making this announcement it was stated the action was taken to relieve the coke situation, both foundry and domestic, which is decidedly light. The furnace has a sufficient stock of foundry and malleable iron on hand to supply demands as foreseen now, and is in a favorable position to resume operations promptly when it becomes necessary.*

•

• Normal attendance was reported during the day shift at the Bethlehem Steel Co. Hoboken Shipyard Feb. 18, following a strike of approximately 1400 workers on the night shift on Feb. 17. George Brown, manager, said the strike delayed work on Navy vessels and cargo ships. The night shift struck over the disciplining of a shop steward who assaulted his supervisor.

•

• Effective at once, establishment of a new basing point for sales of primary lead was announced by OPA on Feb. 22. The new basing point is Bayfield, Wis., and the maximum price for lead, delivered at Bayfield in carload lots, is established at 6.50 per lb. Bayfield was established as an additional basing point because that city has become a lead consuming center, OPA said. The ceiling price is fixed at .10c. higher than ceilings at other basing points cities in Wisconsin to reflect higher freight costs.

•

• WPB announced simplification of allocation procedures for slab zinc. The action, however, in no way relaxes restrictions on its use. Under amended order M-11, remelt zinc is removed from allocation and scrap zinc deliveries are no longer controlled. Another change is that in procedure for applying for and receiving authorizations to accept delivery of slab zinc. The order no longer requires dealers to obtain a preference rating off of AA-5 or better before making shipment. The changes in reference to remelt zinc and scrap zinc become effective immediately, whereas the new allocation procedure becomes effective April 1, following filing of new applications on March 12.

•

• *Reference in L-65 to WPB application forms, used by manufacturers in requesting permission to ship resistance wire and commercial cooking appliances, have been brought up to date through minor revision of that order, WPB announced. At the same time, the form numbers for appeals and reports under the order were brought up to date. The application forms required under the revised order are WPB form 1319 (instead of PD-556), the report form, WPB-1600 (formerly PD-655), and the appeals form, WPB-1477 (formerly PD-500).*

• Donald M. Nelson said reecntly that WPB is examining with leaders of various consumer goods industries the problems that will arise when the time comes for transition back to peace-time production. These discussions are being held with the members of a number of WPB industry advisory committees, and will be supplemented by meetings with labor groups.

•

• B-24 bombers that once cost $238,000 recently were ordered (4500 of them) for $137,000 apiece; a .50-cal. machine gun formerly priced at $510 is now being bought for $210; light tanks which used to cost $45,000 each have fallen in price to $22,564; Garand rifles are available at $42 vs. $116 previously; a 105-mm. shell is priced at $3.75 vs. $5.97 formerly. These were examples cited by Brig. Gen. A. J. Browning last week in stating that the Army is paying 20 per cent less for equipment than two years ago. More than $9 billion has been saved as a result of these reductions.

•

• Charles R. Hook asserted recently that industry faced possible "economic starvation" unless the government assumed a "more reasonable" attitude toward corporate taxation in the postwar period. The Armco head was speaking before the San Francisco Chamber of Commerce.

•

• *H. E. Hall, president of the Metals Disintegrating Co., Inc., Elizabeth, N. J., has been elected president of the Metal Powder Association, a new group of commercial producers of all types of metal powders. Headquarters of the association will be at 60 East 42 Street, New York.*

•

• Industry faces continued severe cuts in war orders in the next few months with complete or partial cancellation of a large number of contracts, according to Brig. Gen. Albert J. Browning, director of purchases of the War Department, who has just been made chairman of the WPB procurement policy board. Aircraft deliveries, however, will make up for a large part of the reduction in deliveries of other goods to the Army, the general said.

•

• With the lower Great Lakes free of ice there is feverish activity preparing the 25 ships wintered at Milwaukee. While shipmasters have not received definite instructions, it is expected navigation will open much earlier than the traditional April 15, according to Harry C. Brockel, Milwaukee port director. Milwaukee has car ferry service across Lake Michigan all winter and there have been several tankers out of Chicago running this winter.

Metal Allotments Made to ODT

• • • **Continuation of** the upward trend in allotment of controlled materials for domestic transportation was reflected today in ODT's announcement of the WPB's allotment for the second quarter of 1944. ODT officials said that for the second quarter of 1944 domestic transportation will receive a total of 1,812,000 tons of carbon steel, or 94.5 per cent of the 1,917,325 tons requested. This allotment constitutes the largest amount made available since the ODT became the claimant agency for domestic transportation under the CMP early in 1943. For the first quarter of this year, the allotment was 1,538,645 tons.

In addition to the carbon steel, ODT was also authorized proportionate amounts of alloy steel, copper, and aluminum. Railroads will be allotted, during the second quarter, the full quantity of new rail which the ODT requested, amounting to 550,000 short tons. Track accessories totaling 291,500 tons were also authorized, plus a further allowance for frogs, switches and other "B" products for track work.

The ODT requested materials to build 25,000 new freight cars and was granted materials for 18,500, which, according to the WPB, is the maximum capacity available for car building for domestic transportation during the third quarter. Third-quarter capacity must be taken into account in setting the second-quarter allotments owing to the lead time required for production.

ODT officials said that orders placed to date by the railroads for new freight cars fall far short of potential production during the third quarter. They emphasized that unless the carriers expedite additional orders, the materials and plant capacity available for that quarter will not be fully utilized. The same considerations apply to subsequent quarters, they added.

Recognizing the increasingly critical situation in automotive replacement parts, the WPB granted the entire ODT request of 137,000 tons of carbon steel for this purpose, a 47 per cent increase over the 93,000 tons granted for the first quarter. While this increased allotment is expected to contribute to improving the general parts situation in the next few months, production difficulties on critical engine, transmission and axle parts are still being encountered. Material requirements for local transport, motor transport and waterways were met practically in their entirety, the ODT said.

Tool Bits Classed as B Product Under CMP by WPB

Washington

• • • **Tool bits, beginning** in April, will be classified under CMP as a B product. Thus, when tool steel is cut to length and heat treated it will no longer be classified as a controlled material.

In a letter to producers of tool steel from J. T. Whiting, director of the WPB Steel Division, it was pointed out that in Schedule I of CMP Regulation 1, amended Feb. 2, 1944, CMP code numbers 2001, 2005, 2501, and 2505 covering carbon and alloy steel bars will not include, after March 31, 1944, "tool steel, irrespective of grinding, when cut to length and heat treated for use as tool bits." In other words, cutting to length and heat treating tool steel for use as tool bits will mark the change of tool steel from a controlled material to "tool bits; metalworking," a class B product, code 362 under the jurisdiction of the WPB Tools Division.

Manufacturers of tool bits will apply for an allotment of controlled material by filing form CMP-4B with the Tools Division, or, if so notified, with the WPB Field Office. Sales will be made to fill rated orders subject to provisions of WPB orders and regulations governing distribution of class B products.

•

Replacement Method Issued For Damaged or Lost Material

Washington

• • • **WPB announced** rules governing replacement of defective material or material which has been lost, stolen, destroyed or damaged in transit when rated orders were placed for it. A supplier must schedule replacement delivery of material on the basis of the original date of the order as follows:

1—If, in the case of defective or damaged material, he is notified within 15 days after the material was delivered by the person who placed the rated order.

2—If, in the case of material lost, stolen, or destroyed in transit, he is notified by the person who placed the rated order within 45 days of the date the material was shipped.

If the notice is received after the 15 or 45 day period, the supplier must schedule the replacement delivery as if he received a separate order on the date the notice is received.

If the purchaser wishes, he may place an order for material that is defective, damaged, destroyed, lost or stolen, with another supplier than the one from whom it was originally ordered, using the same rating as first used. However, the new supplier must treat the order as new order.

Price Briefs

• Amdt. 92 to RSR 14 applies a new pricing system to used and reconditioned valves.

•

• Amdt. 14 to RPS 4 establishes specific dollars-and-cents differentials on railroad steel scrap generated by railroads, car manufacturing companies, and switching companies to determine their ceilings for 35 listed grades of railroad steel scrap. (Release No. OPA-T-1733)

Priority Changes

L-1-j—Amended order eliminates reference to information supplied when filing WPB Form 1319 to sell, transfer or convert fluid-food trucks, trailers, or tank tractors. (2-16-44)

L-53-b—Amended order waives minimum requirement certificate for certain purchases of construction machinery parts. (2-16-44)

L-112—Amended order eliminates reference to information supplied when filing WPB Form 1319 to sell, transfer or convert industrial power trucks. (2-16-44)

L-161—Amended order prohibits use after April 1 of vulcanized fiber tubing in the manufacture of non-renewable electric fuses except under specified conditions. (2-16-44)

L-298—Amended order requires filing WPB-1319 as the authorized form for the delivery of resistance welding equipment. Formerly Form 2752 had to be filed. (2-16-44)

L-332—Order restricts after March 1 all deliveries of new and used container machinery, including that used for packaging and labeling, can closing, can making, glass jar and bottle making and cleaning or reconditioning. (2-16-44)

P-142—Amended order authorizes operators of transportation systems to schedule a majority of materials for the final three quarters of 1944 without the necessity of seeking each quarter's authorization on WPB Form 2585. (2-15-44)

CMP Developments

• Operating Instruction No. 23, Supp. 3, repair shops are not to apply for controlled materials on Form WPB-2613. This form is intended for use in making application for production materials.

•

• Dir. 16 to Reg. 5, permits steel wire used in making brooms to be ordered under procedures applicable to MRO supplies. (Release No. WPB-4997)

Industry Given Credit by Hoover of FBI for Low Rate of

By EUGENE J. HARDY
Washington Staff

o o o

• • • **Hitler's and Tojo's** hopes of disrupting American war production have been blitzed. The vigilance of the Federal Bureau of Investigation and the cooperation of American industry have held industrial sabotage to a minimum. Of 13,672 cases of sabotage reported to the FBI as of Jan. 1, not one was found to be enemy-inspired. In comparison to the enemy-caused destructive explosions and fires of World War I, acts of this sort have been non-existent during this war.

The files of the FBI show 1404 cases of sabotage in some form uncovered in the investigation of the total cases reported. The Department of Justice has obtained convictions of 508 persons in these cases, resulting in 1341 years of sentences, one life imprisonment and six executions up to Jan. 1. The executions accounted for six of the eight Nazi saboteurs who were apprehended by the FBI before they had an opportunity to do their dirty work.

Sabotage has been uncovered in steel mills, aircraft factories, food processing plants, shipyards, railroads and many other American industries. Motivation behind these acts can be classified under five general headings: Carelessness, spite, horseplay, revenge and the desire to become a hero. Faulty machinery and inadequate plant protection are also contributing factors. The FBI archives hold case histories encompassing all of these.

The saboteur acts in many ways to impede production and the industrialist has to maintain a watchful eye if his plant is to be free from destructive acts. Broadly, the types of sabotage may be broken down into three general categories: Arson, explosion and mechanical. Sabotage which has been uncovered and may possibly occur includes many and varied acts. Following are some of the forms of sabotage which may come up at any time during the course of the war:

(1) Damage to machines and equipment by breakage, abrasives and chemicals; (2) destruction of buildings and machinery by use of explosives and time bombs; (3) attempted damage to key points such as power plants and switchboards; (4) injury to raw materials; (5) creation of fire hazards; (6) bacterial hazards, water and food; (7) theft or damage to blueprints or models; (8) damage or destruction to main transportation routes; (9) injury to precision tools.

With the outbreak of war in Europe on September, 1939, the FBI commenced surveys of all the major industrial plants engaged in war production or designated by the War and Navy Departments as vital. Over 2400 plants were inspected. The surveys showed many cases where carelessness and lack of knowledge of plant protection may have resulted in immeasurable damage had they not been corrected. The FBI found industry extremely cooperative and in all cases speedily remedied conditions discovered by special agents.

In one plant agents discovered that the average age of guards was above 64 years, with some individuals over 80. On a military reservation children living there were given a master key which opened the gates, as a shortcut to school. These children were relied upon to lock the gates after them. In a case of another sort irreplaceable plans and working models of successful experimental government machinery were kept in a flimsy building, protected by two carbon tetrachloride fire extinguishers, which are valueless against wood fires and other combustibles of that type. A great number of plants had fire extinguishers which hadn't been recharged in years, as well as rotten fire hose.

Many plants were found to have inadeqate employee identification systems. Too great reliance was placed on time clocks, but it was quickly pointed out that anyone can punch a time clock, resulting in the adoption of photographic badges as a means of identification in a great number of cases.

A hobo was discovered on a government proving ground. On questioning it was learned that he had been living there for three days without having been challenged. FBI officials emphasize the necessity of maintaining proper systems of employee identification, as one of the major points in protection against sabotage.

In quite another type of case in which the employee was at fault the FBI learned that several barrels of tools, valued at several thousand dollars had been recovered from employees who were taking them from the plant. This happened when a local news photographer asked permission to have the gates closed to enable him to get good picture of crowds leaving the plant. The word soon spread through the plant that the gates were closed so that employees could be searched before leaving the plant and pockets were soon emptied. As trivial as this incident may seem the loss of equipment might become serious if carried on indefinitely.

Other dangers discovered in the FBI survey include fire hazards where spontaneous combustion could have been the igniting agent and cases where vaults constructed to house blueprints and models had wooden floors, and glass windows facing the street, despite the elaborate steel doors and combination locks.

FBI Director J. Edgar Hoover told THE IRON AGE that "the low rate of sabotage has been due in a large measure to the fact that industry has taken due precautions to guard against it."

Another step taken by the FBI to protect American industry from the dangers of sabotage and provide security at home was taken immediately after the Japanese sneak attack with the inception of the alien enemy program by residential directive. Within 24 hr. after Pearl Harbor over 1400 alien enemies of the most dangerous type for many months known to the FBI were taken into custody. Up to Jan. 7, 1944, the FBI with the cooperation of local law enforcement officers, had taken 15,103 alien enemies into custody. These included 5335 Japanese, 6191 Germans, 3553 Italians and 24 Bulgarians, Rumanians and Hungarians. Of these 5176 have been interned, 4820 paroled, 2908 released without further hearing and the remainder released after hearing.

Large quantities of dangerous material have been confiscated from the

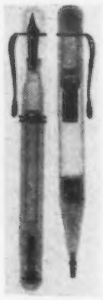
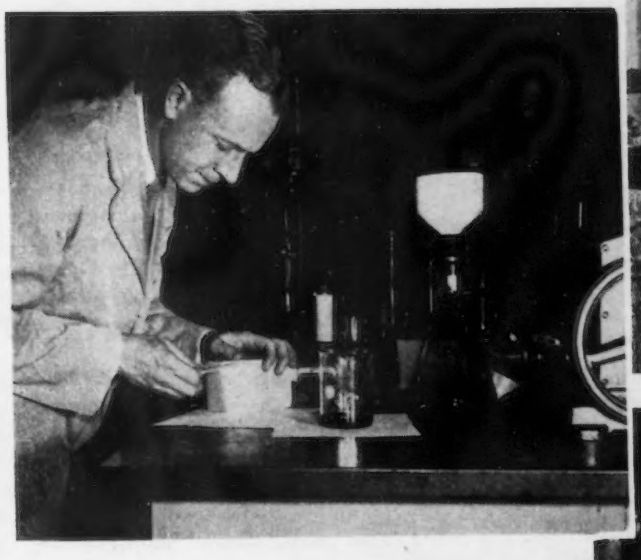
Industrial Sabotage During This War

Much Malicious Work Uncovered in Mills and Factories, but No Cases Inspired by Enemy; Carelessness, Spite, Horse-play, Revenge Among the Many Motives



• Part of Nazi saboteurs' equipment—incendiary pen and pencil set, shown by means of X-ray photo. At right, group of German saboteurs who were executed or imprisoned.

F.B.I. Chief J. Edgar Hoover



• Because of the acts of two small boys, more than $1,000,000 worth of patterns burned in the plant shown in ruins af extreme right. The boys went into the plant carrying a pot containing burning paper and wood, then fled when they saw a "ghost."

Below, at right, equipment of Nazi saboteurs is shown. This box contained ten blocks of TNT and four bombs resembling coal.

Above, FBI scientist is examining TNT blocks brought by German saboteurs.

IF YOUR PLANT is one of the ever-growing number that is extending the useful life of tools, dies, gauges and other production machine parts by hard chrome plating, you will find that the FIRST important STEP in getting successful results is THOROUGH DEGREASING. Surfaces must be CHEMICALLY CLEAN . . . insoluble smut, grease, shop dirt, oil and other accumulations completely removed to assure durable, uniform finishes.

No wonder, then, that many plants, to put this essential cleaning work on a trouble-free, low-cost basis, are using

OAKITE DEGREASING MATERIALS

Applied either by still tank cleaning, anodic degreasing or cathodic cleaning methods, these effective, fast-working materials have effective wetting-out, emulsifying and penetrating properties that SPEEDILY, COMPLETELY remove ALL accumulations. As a result, surfaces are left in the chemically clean, smut-free condition required for the proper adhesion and uniformity of the subsequent chromium plate.

Successful, time-saving, economical Oakite acid-detergent techniques also are available for thoroughly yet safely stripping old chromium plate, wherever necessary, prior to replating.

WRITE FOR *FREE* DETAILS *TODAY!*

Your nearby Oakite Technical Service Representative will be glad to place at your disposal his specialized knowledge and experience on this or any other degreasing and cleaning job you want performed faster, easier or at low cost! Write today . . . no obligation whatever, of course.

homes of these aliens, including 4626 firearms, 306,247 rounds of ammunition, 2300 sticks of dynamite, 2800 dynamite caps and several thousand radio sets and cameras.

Actual cases of sabotage discovered by the FBI show a wide variety of motives and methods, In March, 1943, Eduardo Gonzales, a 19-year-old employee of the Warman Steel Casting Co., Los Angeles, struck an electric furnace with a sledge hammer until the inside brick lining collapsed. On being called into the case FBI officials found that other employees had seen Gonzales committing the damage in question. He threatened to kill anyone who told of seeing him smash the furnace, but five signed statements were obtained. After the lining collapsed the furnace had to be shut off to prevent its destruction.

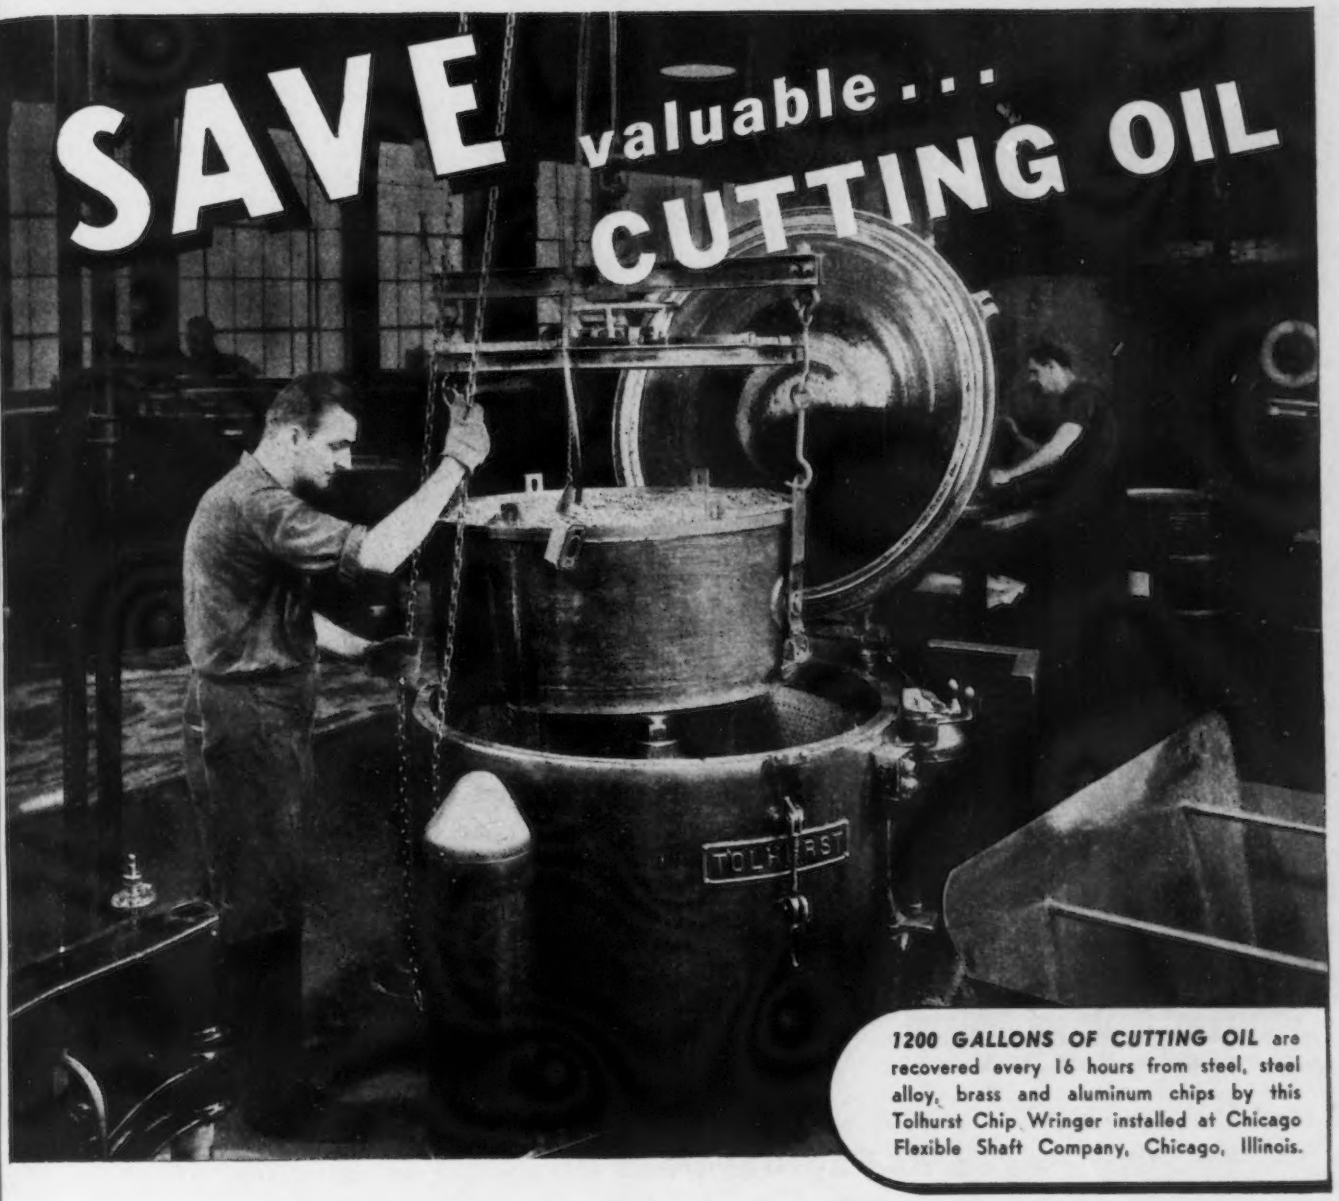
When confronted with this evidence Gonzales admitted the act and gave as his reason his desire to leave the plant early to keep a date with a girl. Gonzales was employed as a melter at the plant and when the furnace was shut down he went home.

He was connected with the "Zoot Suit Gangs" and had a criminal record. He entered a plea of guilty, was given a two-year suspended sentence and placed on probation for five years.

In a case involving spite as the motive, a young 32-year-old carpenter at the Glenn L. Martin Co. plant, Baltimore, was convicted and placed on probation for one-and-a-half years on condition that he make monetary restitution for damage done to an airplane engine shipping case and self-sealing airplane tank. Investigation revealed that he was notoriously headstrong and spiteful among his fellow-workers.

He readily admitted his acts and explained the damage to the shipping case as resentment against a supervisor who ordered him to move the case several times. The only explanation unearthed for damage to the tank, which happened on the same day, was that he was on a rampage.

FBI files also hold the case of a young man employed by the Crown Cork & Seal Co., Baltimore, who plugged fire extinguishers and cut fire hose to create a sabotage scare, which he would discover and emerge a hero. On one occasion he claimed a hose had been plugged before he looked into it and after several slips of this sort he was confronted with the evidence. After pleading not guilty, he was convicted and sentenced to serve



1200 GALLONS OF CUTTING OIL are recovered every 16 hours from steel, steel alloy, brass and aluminum chips by this Tolhurst Chip Wringer installed at Chicago Flexible Shaft Company, Chicago, Illinois.

TOLHURST CHIP WRINGERS recover up to 98.6% of valuable cutting oil from metal chips, through the application of *centrifugal force only*. The routine is very simple and unskilled help can efficiently operate Tolhurst Chip Wringers.

REDUCE TOOL WEAR A plentiful daily supply of fresh, reclaimed oil encourages a more conscientious use of cutting oil. Tool room records show reductions in tool wear run as much as 50% after installing Tolhurst equipment. Frequent collection and processing of chips result in cleaner floors and reduce the hazard of fire. Investigate Tolhurst Chip Wringers for conserving cutting oil — reducing tool wear. Details gladly sent upon request.

15 months. He also had a prior criminal record.

A series of fires committed against the Southern Pacific Railroad were discovered to have been the work of a man who had a desire for revenge against the United States and all humanity. Vincent Palokis was born in Latvia and came to this country in 1908 or 1909. He worked on occasions as a farm laborer but spent most of his life as a hobo and never thought enough of the United States to become a citizen. He was a member of the I.W.W. and has served a jail sentence.

After being taken into custody he boasted to special agents that he did not recognize the American flag and claimed that he would rather be imprisoned or shot than to serve in the United States Army. He also predicted that the United States would be overthrown by force and violence in 1945.

For destroying property of the Southern Pacific Railroad consisting of four bridges, two railroad section houses, three refrigerator cars and two unimportant houses, valued at thousands of dollars, he was sentenced to 15 years in prison after a trial by jury.

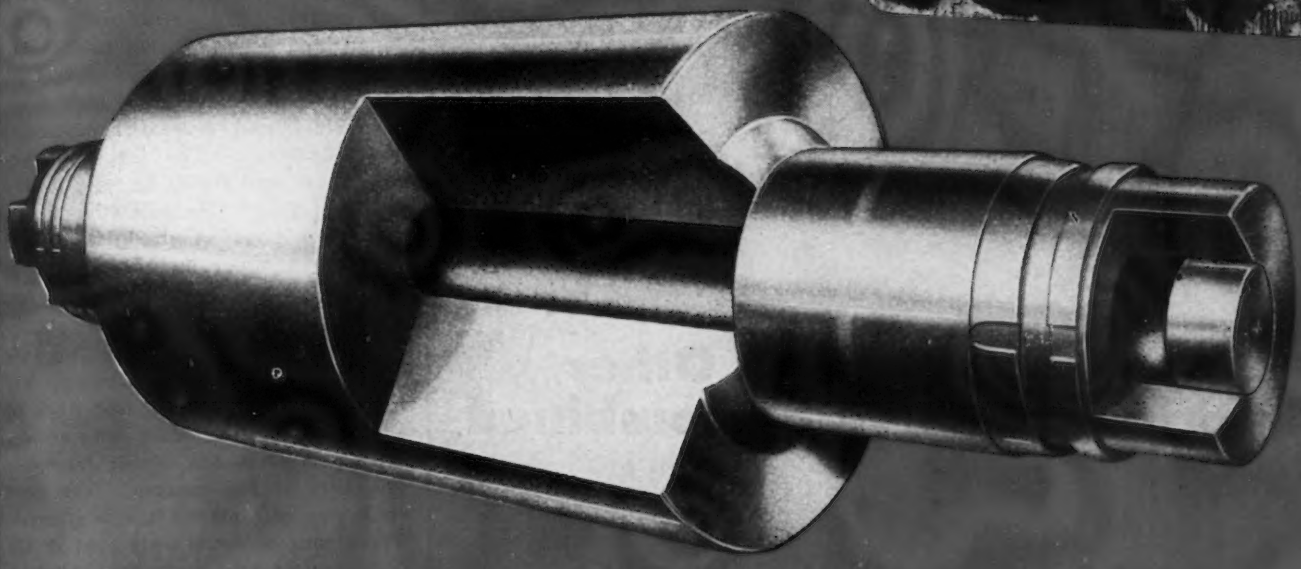
The FBI was called in when glass particles were mysteriously appearing in the hydraulic landing gear systems of Army pursuit planes. After intensive investigation for sabotage special agents discovered the glass was coming from a faulty hydraulic testing device.

Last fall a shipyard laborer was arrested at Orange, Tex., for placing launching wax in locks on seven tool chests and three nipples on storage tanks. The tanks and chests were on a destroyer escort under construction at the plant. Had this ship gone to sea without this being discovered damage might have been extensive. The laborer claimed he did it as a prank and did not intend to harm the United States or his employer.

"To get in some overtime work," an electrician in a West Virginia aircraft factory struck a lead-covered cable with a pair of side cutters, damaging it. The laborer confessed his guilt to FBI agents and said he was intoxicated when the damage was inflicted.

At Waltham, Mass., pieces of wire found in the gears of three important machines provided a sabotage mystery. Investigation by the FBI revealed that employees of that department were in the habit of throwing

OHIO ROLLS—"BEARS FOR PUNISHMENT"



HOLL-O-CAST STEEL ROLLS

have more strength and hardness

because they're heat treated

inside and out

These Rolls are cast with a hole through the center. Rolls cast in this manner have four big advantages:

1. Reduction of ingotism.
2. Positive elimination of internal hot rupture.
3. Stronger resistance to fatigue in the necks.
4. Improvement in heat treating process.

The balanced alloy steel in Ohio HOLL-O-CAST Steel Rolls is selected for strength—and much greater strength is attainable through this special heat treatment than by analysis alone.

SELECT FROM ANY OF THESE 9 TYPES OF OHIO STEEL AND IRON ROLLS:

Carbon Steel Rolls
Ohioloy Rolls
Ohioloy "K" Rolls
HOLL-O-CAST Rolls
Chilled Iron Rolls
Denso Iron Rolls

such metal objects at each other an the wire obviously fell into the ma chines in the course of such horsepla Machines were out of production whi repairs were made.

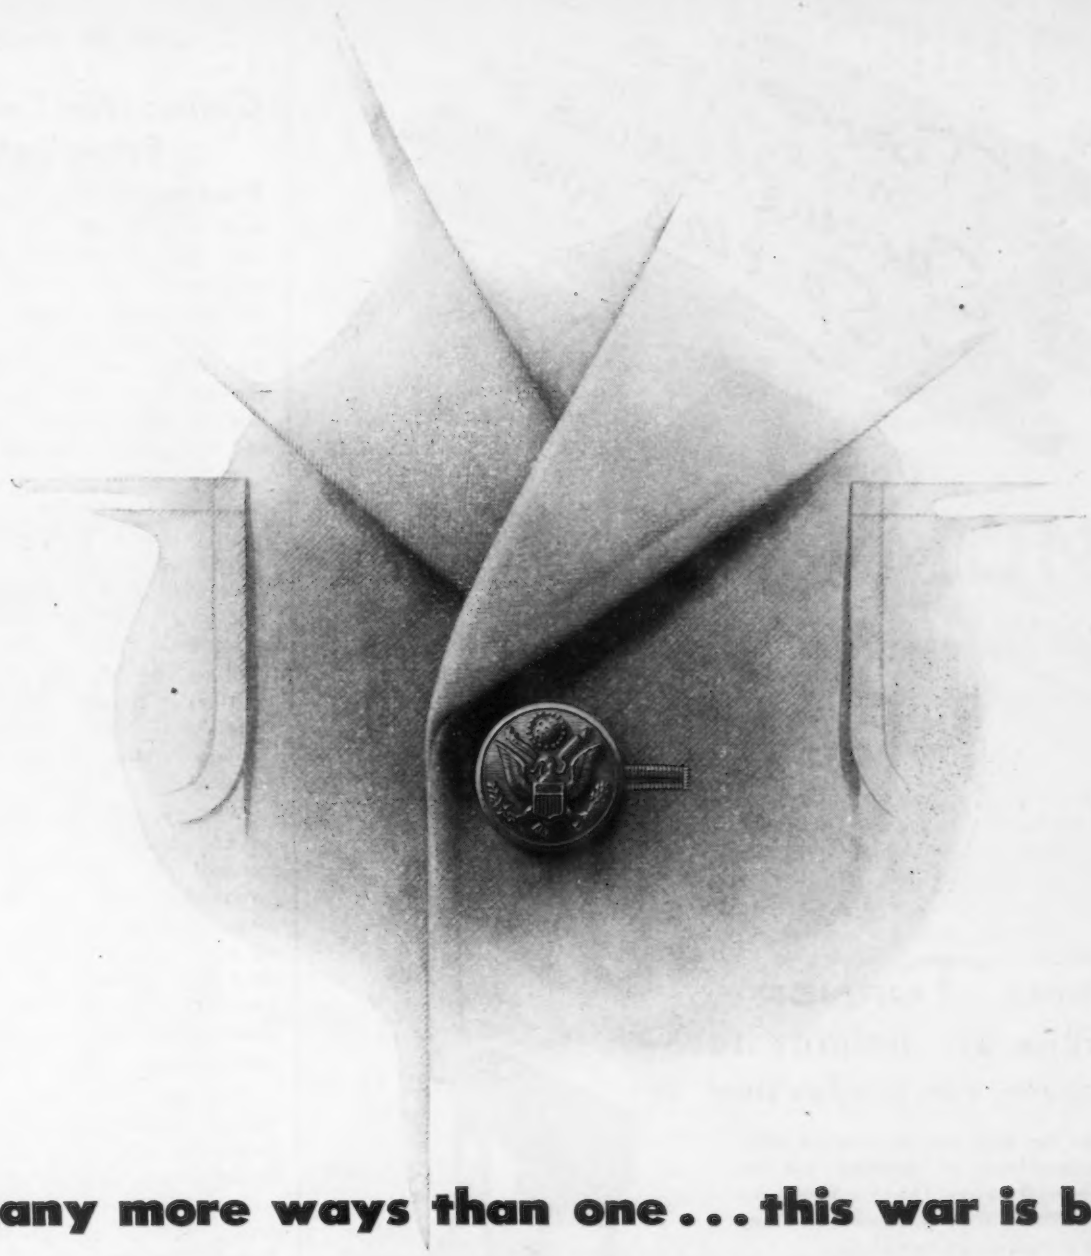
Several cases of suspected sabotag were reported at an Illinois factor It developed that an inspector of ai bombs had twice changed all electri cal controls, had turned off an ai valve, and several times had turne off the water valves of electrical ar welders. As a result, 1000 man hour were lost and several bomb case were damaged. The inspector wa questioned and stated he "did it in spirit of fun!" He pointed out tha the other boys at the plant woul hide his hammer and he wanted t get even. His horseplay cost hi his job.

The production of soup for th Army at a company in Chicago wa held up for a period of one week b 16-year-old Victor Mule, who stole vital part from one of the machine and held it for ransom. The par could not be replaced in this country Three ransom notes were sent to th president of the company. After week had elapsed Mule returned th part, because he had become fright ened when the FBI took over th case. He said he took the part be cause he disliked the president of th company and after having obtained it he decided to demand some money for its return.

Cases of sabotage, intentional and mere horseplay, in the FBI files would fill many pages, but American indus try is well aware of what its problem is, having experienced sabotage or horseplay, which has held up produc tion in almost every type of plant.

"Despite the fact that the peak of war production is in sight, no foreign-directed sabotage has been discovered and the home front is outwardly quiet, industry should not relax any work done along lines of plant protection," said Mr. Hoover. "There is no reason to believe there will be no sabotage, for with the Axis losing on all fronts they will no doubt resort to some drastic last-ditch action, which very likely might be a blow against the production front."

Since the Army has withdrawn all of its guards from plants throughout the country with the exception of those manufacturing secret and critical war materials, Mr. Hoover's admonition should take on a new meaning. Approximately 14,000 soldiers have been relieved of guard duty in various ordnance plants.



In many more ways than one . . . this war is being

"BUTTONED UP" WITH BRASS

TO THE CIVILIAN EYE, Brass is either the parade dress or the battle dress of war . . . either uniform insignia and band instruments, or sleek and shining cartridges and shells. Yet in between these two extremes, Brass has a vast and varied tour of duty on scores of "undercover" jobs . . . as in gun mounts and breech mechanisms, aircraft gyros and navigating instruments, radios, searchlights, sound-detection equipment, ship's engine-room piping and propulsion mechanisms, binnacles, compasses, hospital equipment. And there are countless other functions in which the extraordinary ductility, malleability, durability and corrosion resistance of Brass have never been approached by any other material.

Today the entire energies and resources of this organization are bent to one end: To make every inch of Bristol Brass sheet, rod and wire so thoroughly fit . . . both physically and dimensionally . . . that there will be not one moment of production delay in the plants that make Bristol Brass into munitions and materiel . . . nor any shade of doubt as to its *sure-fire* dependability, when lives depend upon it in action. Yes, Bristol Brass is helping speed *the* day!

Civilian Steel Cut Below Stated Need

Washington

• • • **Although cut slightly** mo than 7 per cent below their reques civilian allotments for carbon ste for the second quarter were increas by 55,000 tons over the first quarte The second quarter allotments grant the Office of Civilian Requiremen are 210,000 tons compared with 15 000 tons allotted for the first quarte

The second quarter allotments controlled materials, announced chairman J. A. Krug of the WPB R quirements Committee, represented scaling down of approximately 1,000 000 tons of stated carbon steel re quirements for the 14 military an civilian agencies. He stated that th military claimants, Army, Navy an Maritime Commission, received slight ly less than their stated require ments.

While pointing out that the suppl of and demand for basic metals ar virtually in balance for all essenti production programs, Mr. Krug em phasized that the increased allotmen of steel for civilian use does not re flect any change in WPB's policy fo restricting the production of civilia goods to the basic essentials, pendin clarification of military trends.

The increased allocation for th second quarter, Mr. Krug said, wil go for the production of those civilia items already authorized by the boar as essential to workers on the hom front. It was not disclosed in Mr Krug's statement but this civilia production will take a new turn i that the Victory specifications fo plumbing and heating products wil be dropped and the output of standard items will be resumed. The other civilian items already approved fo production include such lines as elec tric irons, electric ranges, flashlight cases and pots and pans.

National Steel Earnings Total $11,698,361

• • • **National Steel Corp.** reported preliminary net earnings for the year 1943, after all charges including a re serve of $750,000 for contingencies, of $11,698,361.70. This compares with earnings for the preceding year of $11,929,867.43. Net earnings for the fourth quarter of 1943 were $3,279,- 885.17, compared with earnings in the fourth quarter of 1942 of $3,664,701.32, equal to $1.66 per share.

IN THE QUANTITY PRODUCTION OF SMALL METAL PARTS

WITH POMET

Under the stress of war-time demands, this plant has sped the development of powder metallurgy from the pioneer phases of a new process to practical production routines. Today Pomet parts are saving time, material and labor for many manufacturers who wish to combine high standards with quantity production. A wide variety of complicated parts can be produced quickly and economically using brass, bronze, aluminum, ferrous alloys and other metals, combinations of metals or metals combined with non-metallic powders.

POMET *also gives you these "PLUS" qualities:*

- **CLOSE TOLERANCES WITHOUT MACHINING** In many cases, finished pieces can be held to tolerances of plus or minus .001" or even closer, with all or most of the need for expensive machining eliminated.
- **DENSITY** Small parts which approach high technical density can be made. Complex Pomet parts often satisfactorily replace machine parts which were made by conventional methods.
- **CONTROLLED POROSITY** Pomet parts can be made with intentional porosity for special applications or porosity can be reduced to 5%.
- **WEAR RESISTANCE** Pomet parts can be made to resist strains and stresses such as tension, compression, shearing and abrasion and, in many cases, they out-perform the more expensive parts they replace.
- **DUCTILITY OR HARDNESS** When high ductility is a necessary characteristic, it can be incorporated in Pomet parts. Hardness is also a property that Pomet parts can give you when it is required.
- **COMBINED MATERIALS** Special combinations of metals, where two or more qualities are desired, can be satisfactorily accomplished in Pomet parts. Metals and non-metals can also be combined for the production of cutting and abrasive units.

New and greatly expanded facilities now assure even faster production. Technical excellence is being maintained and constantly improved. In quantities of 20,000 and over Pomet parts are particularly interesting to manufacturers who have to keep cost in line with rigid specifications. We will be pleased to quote on blueprints and specifications, and are in a position to give you exceptional service. We shall also be glad to send interesting and informative literature on request.

POWDER METALLURGY

CORPORATION

A SUBSIDIARY OF GENERAL BRONZE CORPORATION

30-42 Greenpoint Avenue **Long Island City, N. Y.**

HATCHED IN THE OPEN HEARTH

Their strength and ability to take it begins in the Open Hearth that produces high quality steel for the world's finest war planes. Andrews is proud to be one of the steel manufacturers whose product meets the exacting requirements of aircraft producers. Aircraft alloy and carbon steel sheets are made in a wide range of sizes and thicknesses to meet specifications AN-QQ-S-685 (X-4130). AN-QQ-S-686 (X-4135). AN-QQ-S-756 (X-4340). AN-S-11 (SAE 1020-1025). AN-S-12 (NE-8630). AN-S-22 (NE-8635). Information on request.

The Andrews Steel Company produces a limited range of aircraft quality alloy plates

New WPB Form 1319 Will Replace 20 Separate Forms

Washington

• • • To save paperwork and time in handling applications for authorization to purchase or deliver equipment, the new WPB Form 1319 will supplant the old variations of Form 1319 as well as many others, and will cover the entire field with the exception of those coming under the head of the old PD-1a and PD-3a, which are applications for certain preference ratings.

The new form, covering four pages, will have the same places of filing, same number of copies, and same methods of processing as the present forms. The net result is that only one instruction book and one form will control such applications. Copies of the instruction book will be included in "Products and Priorities" monthly publication of the board designed to keep executives and manufacturers informed on current orders and forms.

Inland Will Restore Old Greenwood Furnace

Chicago

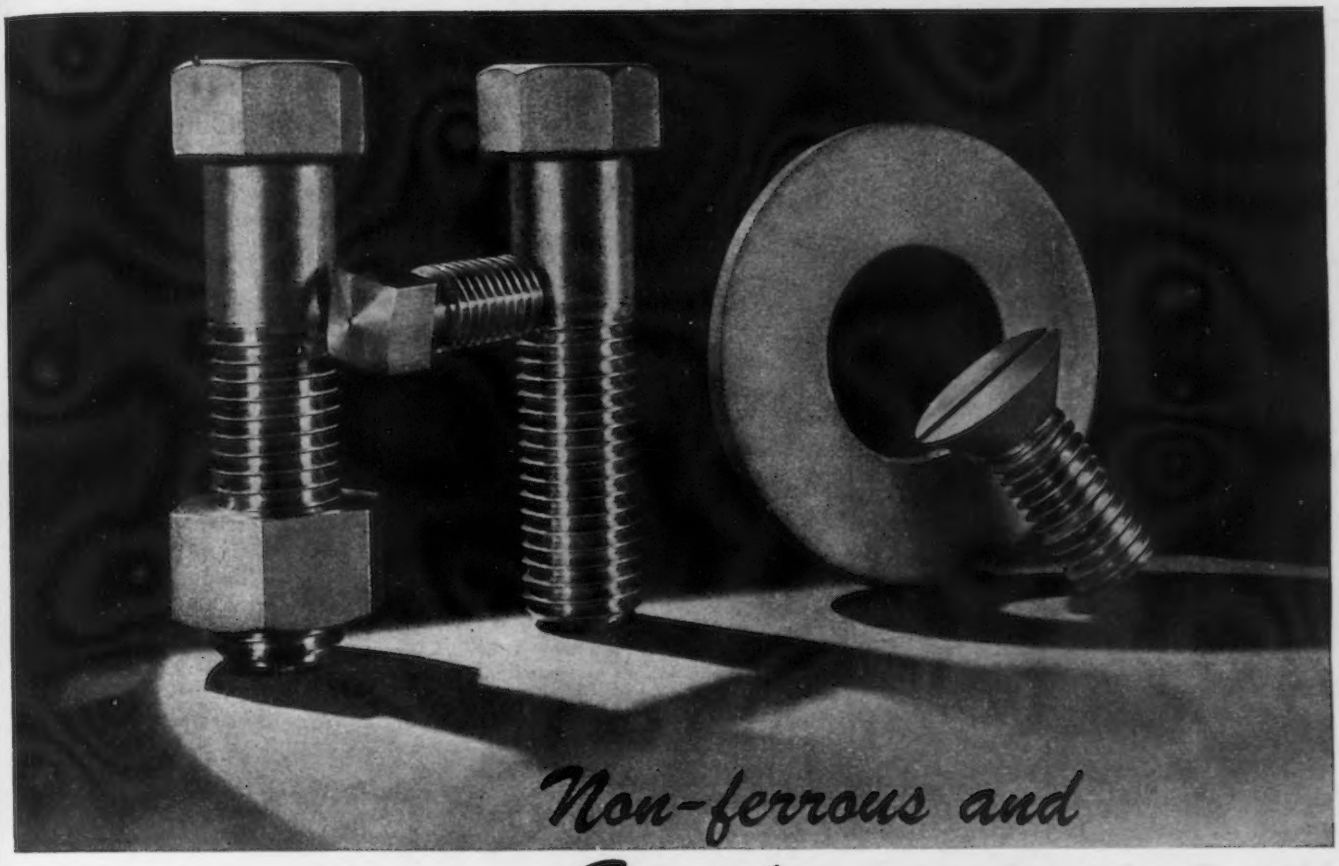
• • • The Inland Steel Co. has announced the purchase of the old Greenwood Furnace west of Ishpeming, Mich., built during the last year of the Civil War for the production of charcoal iron. It now stands as an isolated relic in the woods not far from Inland's Greenwood Mine. The company plans to restore this furnace as nearly as possible to its former state and believes this can be done without using critical manpower or material.

Buyers Trim Inventories of Iron

Buffalo

• • • A Buffalo iron maker running malleable and foundry grades (Tonawanda Iron Works) reports a tendency on the part of buyers to reduce inventories and become more particular about shipping dates and analyses. Also noticeable with the lifting of allocations is a disinclination by the foundry trade to over-order.

While this iron maker reports business on about the same basis as before allocations were halted, he has increased his inventory by 2000 tons since Dec. 1. He now has about 7500 tons in reserve, divided into some 20 to 25 different grades, which he regards as just enough for "elbow room," something he has not had for many months.



Stainless FASTENING

Headquarters

HEADQUARTERS is "a chief place of business." So . . . . . when you need non-ferrous and stainless fastenings, come to Harpers . . . the organization which specializes on the manufacture of bolts, nuts, screws, washers, rivets and specials made of Brass, Bronze, Copper, Everdur, Monel and Stainless . . . an organization not concerned with common steel fastenings.

To serve fastening users, Harper stocks over 4280 different items . . . employs a large staff of engineers and field service men . . . and offers a vast fund of practical non-ferrous and stainless fastening "Know how." Sample this "Know how" by writing (on your letterhead) for a 4-color, 84 page catalog.

HERE'S HOW YOU CAN "Get in the Scrap!"

This A-F Pan-Type Overlapping Beaded Apron Conveyor takes the scrap (via slides) directly from the stamping presses and conveys it out through the wall to a long reversing conveyor of similar construction, which, in turn, conveys the scrap to cars at one end—or to an inclined apron conveyor discharging into trucks at the other end of the line.

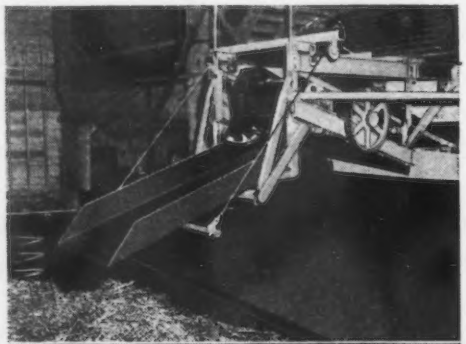
★ ★ ★ ★ ★ ★ ★

Alvey-Ferguson Scrap Salvaging Conveyors Help You to More Efficient Scrap Conversion

YOU KNOW that scrap reserves are declining—and at an alarming rate. Scrap that is needed for vital war products. You've been asked by Uncle Sam to back up the Nation's Scrap Conservation Campaign. But How?

Here's the first really practical, efficient and economical method—the use of an A-F *Scientifically-Planned* Scrap Salvaging System especially adapted for *your* plant!

This photograph shows how the scrap is discharged directly into the cars for immediate shipment to scrap salvaging plants. No trucks are used. No manpower is wasted.



The bottom photograph shows how the A-F Portable Conveyor units carry the scrap discharged from the main conveyor directly to a trailer truck for movement to a steel mill. After one trailer truck has been loaded, scrap can be dumped into either of two other lined-up empty trucks.

Whatever your scrap salvaging, material handling, and metal products cleaning and finishing problems—write us today.

Nelson Explains How Farm Supply Output Is Aided

Washington

• • • **Recognizing the importance** of the farmer in the country's war production programs, and the necessity of maintaining an adequate flow of machinery and equipment to farmers, WPB Chairman Donald M. Nelson in a memorandum to his executive staff, dated Feb. 7, outlined the steps being taken by WPB to aid the manufacture and distribution of farm supplies. The wording of the memorandum indicates that it takes the form of a directive, springing from PD-19 and M-330 establishing a basic policy for the manufacture and distribution of farm supplies.

Mehl to Lecture at Brazilian University

• • • **Dr. Robert F. Mehl,** professor and head of the Department of Metallurgical Engineering and director of the Metals Research Laboratory of the Carnegie Institute of Technology, Pittsburgh, has left this country to deliver the second of a series of lectures on metallurgy at the Escola Politecnica of the University of Sao Paulo, Brazil, in a new lectureship on this subject established last summer.

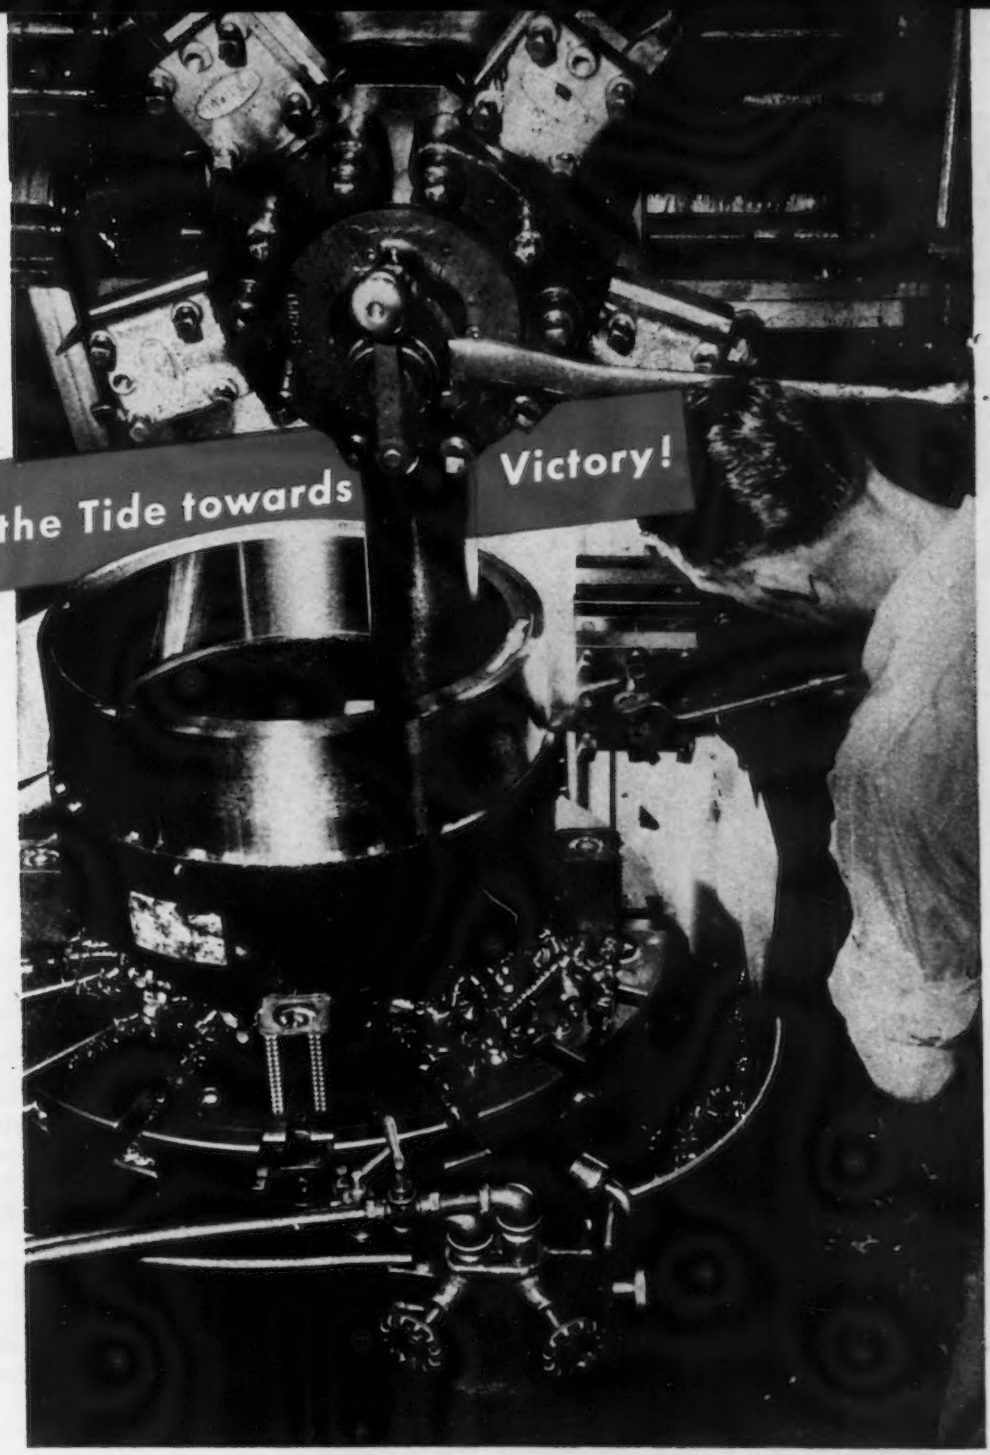
Tungsten-Molybdenum Alloy Distribution System Altered

Washington

• • • **Producers of tungsten,** molybdenum and their alloys are being given an opportunity to schedule that production better through an amendment order M-369, which covers the terms under which these are distributed, WPB reported. The amendment permits each person seeking to acquire such products to make written application to WPB not later than the "first day of the second month preceding the month in which such delivery is desired."

GE Research Director Receives Faraday Medal

• • • **Dr. Irving Langmuir,** associate director of the General Electric Research Laboratory, was awarded the Faraday Medal of the Institution of Electrical Engineers, London, according to a radiogram he has received from Stanley Angwin, president of the Institution. Plans for its actual presentation will be made later.



Big jobs on big, high powered and fast machines—jobs held to extremely fine limits of accuracy. That's the formula which spells success to the Marine Construction program. One of these big jobs is illustrated above . . . turning and boring a part for a Marine Turbine . . . the censored production data would shock the enemy . . . the accuracy, typical of all work on Bullards, is easily held to very close limits. For obviously the machine is the famous Bullard Vertical Turret Lathe, with rapid power traverse for the swiveling turret head. Two heads cutting simultaneously with independent feeds shorten cutting time. Indexing of one head while the other continues its operation cuts lost time between cuts. Consult with Bullard engineers for aid in TURNING the tide towards Victory!

Procedure Simplified for Class B Product Manufacturers

Washington

• • • **The WPB Controlled** Materials Division on Feb. 11, announced a simplified procedure under which manufacturers of one product, part of the output of which are Class B products and the rest of which are unclassified products, may file a single Controlled Materials Plan-4B application to cover the entire production of the item. Allotments of controlled materials for the manufacture of Class B products are obtained from WPB Industry divisions. Unclassified products are those that do not contain controlled materials forms or shapes of copper, aluminum or steel.

If the manufacturer elects to file the single CMP-4B application for his entire production, he must explain in a letter accompanying it that the products covered include both Class B and unclassified products.

No Ease Sighted for Enamel or Galvanized Ware

Washington

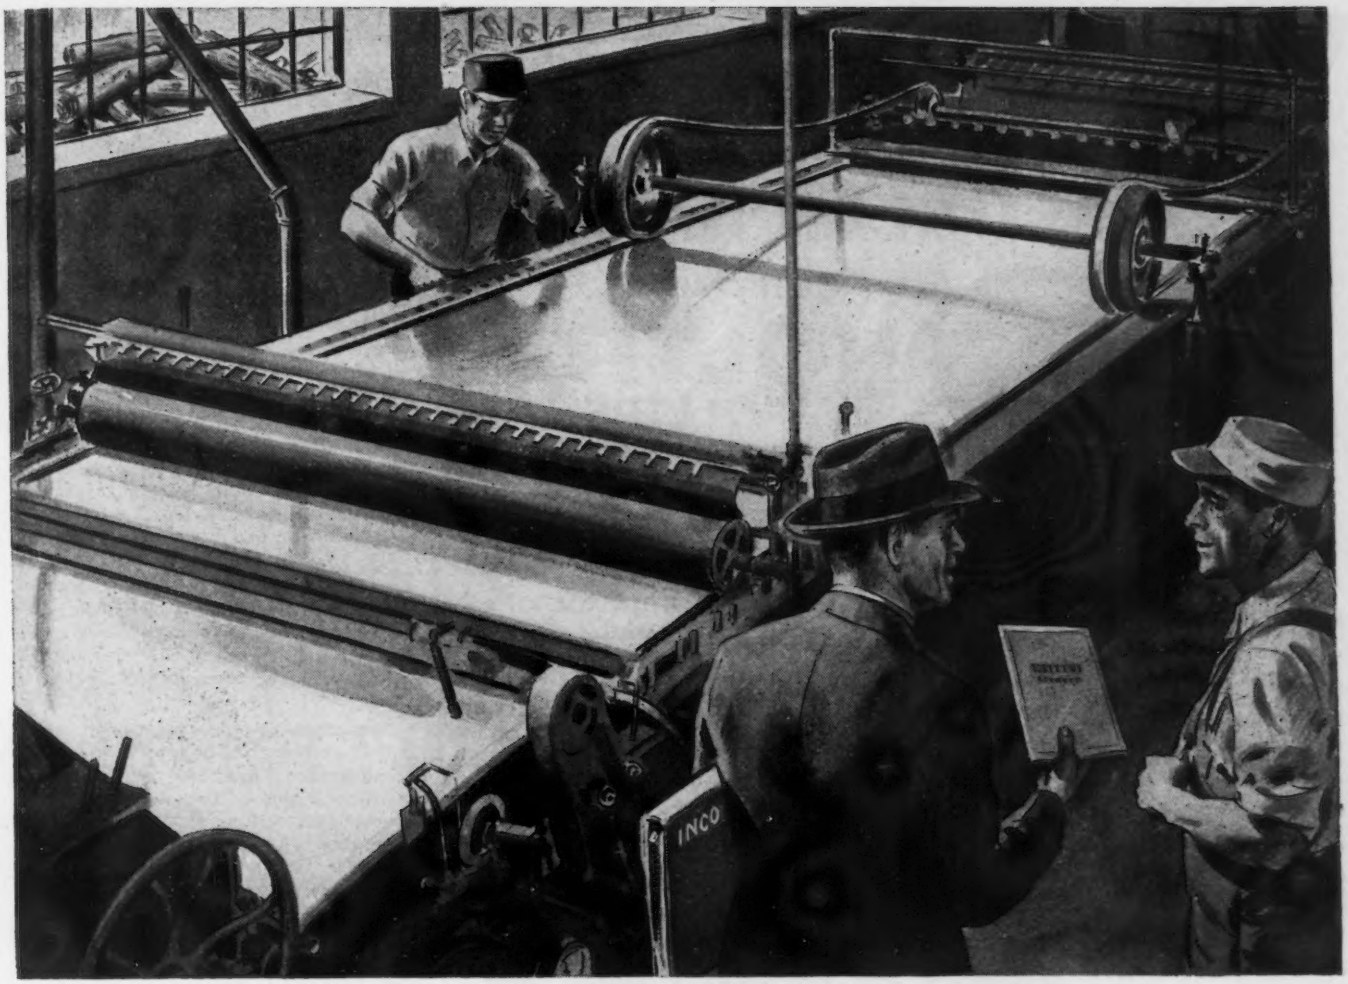
• • • **The WPB Galvanized** Ware Manufacturers Industry Advisory Committee has been told that while galvanized ware requirements for the second quarter of this year are being given serious consideration by WPB, no large-scale relaxation of the controls over production of civilian goods in general can be considered until the outcome of impending military operations is known.

A major factor in connection with galvanized ware production is the short supply of galvanized sheets. A large part of the sheet rolling capacity is needed for the fabrication of steel plates for ships, tanks, landing barges, and other war goods. Consequently, facilities for rolling galvanized sheets are and will continue to be extremely limited.

Adams Directs Consumer Goods

Washington

• • • **The appointment of** Stanley Adams as director of the Consumers Durable Goods division of WPB was announced. Mr. Adams has been connected with WPB and its predecessor agency, OPM, since May 19, 1941.



NICKEL AIDS THE PAPER AND PULP INDUSTRY

to KEEP 'EM PRODUCING!

"Paper is one of the sinews of war" . . .

A basic tool of communication . . . strategic substitute for metal in many products.

Made, for example, into new export containers that protect their contents against water, vapor, and grease, it's a vital factor in the Battle of Supply.

So the need is tremendous . . .

And the industry's vast output is possible largely because paper-making is almost entirely a machine process.

Plant engineers agree that when you depend so much on machinery, you'd better have machines that are dependable.

That is why . . . thanks to those engineers and the machine designers . . . equipment in paper and pulp mills includes large amounts of Nickel alloyed materials.

Metals so fortified help a lot to keep machines producing, because Nickel imparts toughness . . . strength . . . corrosion resistance.

Thus, when properly used in critical parts, "a little Nickel goes a long way" toward increasing dependability.

From grinder cylinders to dryer rolls, from digesters and save-all pans to Fourdrinier rails and beams, Nickel alloyed parts stand up better to abrasion, wear, and corrosive chemicals.

We have long enjoyed the privilege of cooperating with technical men interested in the selection, fabrication, and heat treatment of metals . . . not only in the paper industry but in many others. Whatever *your* industry may be . . . if you'd like to have such assistance . . . counsel and printed data are available on request.

New Catalog Index

New Catalog C makes it easy for you to get Nickel literature. It gives you capsule synopses of booklets and bulletins on a wide variety of subjects—from industrial applications to metallurgical data and working instructions. Why not send for your copy of Catalog C today?

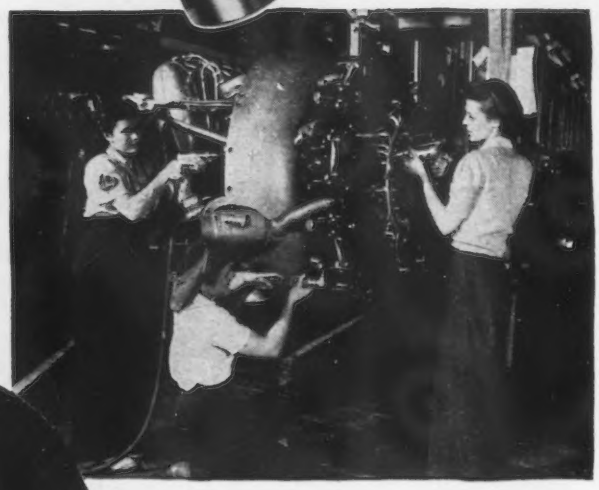
WOMEN WORKERS AND ALL GREEN HANDS can drive HOLTITE —PHILLIPS— SCREWS and BOLTS

with speed, safety and efficiency! Basic training time for inexperienced workers is cut to a minimum and production increased without hazards of injuries, spoiled work or burred heads.

The illustration below shows a specific instance of the proficiency in power driving that can be attained by women workers. At the Consolidated Vultee Aircraft Corporation in some departments power tools replace hand-driven screw drivers and wrenches commonly used when men were employed. This production - boosting operation has been made possible by the adoption of recessed head screws. By this modern fastening practice, experienced workers can cut fastening time up to 50% and more.



When Speed Nuts are used with HOLTITE Sheet Metal Screws in place of machine screws, another saving in production time is effected, as the small tapered point permits a quicker start when nuts are run on. The smooth threads with faster lead reduce turning time and provide a tighter lock to defy vibration.

HOLTITE "Thread-Forming" Sheet Metal Screws eliminate tapping operations by cutting their own threads in the material as they are driven in. For all metal-to-metal fastenings, specify HOLTITE Type "A," "Z" or "C" sheet metal screws.

CONTINENTAL SCREW CO. New Bedford, Mass., U.S.A.

BUY MORE WAR BONDS

News in Brief

• Pratt & Letchworth Co., Inc., Buffalo, is making railroad castings on a subcontract for use on Russian locomotives and freight cars. The plant is diverting facilities to production of more railroad equipment, its peacetime specialty, as war orders near completion. The foundry recently installed a 1000-kv X-ray unit.

•

• Maday Body Works, Buffalo, completed government orders for converting small trucks into larger Army units and will revert back to its peacetime field of repairing and rebuilding bodies of motor-transport equipment. Employment will be cut slightly.

•

• Producing chains for all battlefronts, Columbus McKinnon Chain Corp. of Tonawanda, N. Y., reports enough back orders to keep its plants operating at capacity for the remainder of 1944.

•

• General Drop Forge division of Brown Lipe Gear Co., Buffalo, reports production has increased about 500 per cent in the past three years. General Drop Forge was bought by Brown Lipe in 1941 and more than $2,000,000 has been spent on expansion. Output of forgings for landing craft engines is being increased but more than half the plant's production continues to go to the aircraft industry.

•

• The Industrial Marketers of New Jersey are holding a Fact Forum for the Future on March 21, at the Essex House, Newark, N. J. It will highlight the facts about applications of light metals, plastics, electronics, synthetic rubbers, and light airplanes after the war. A speaker from a leading company in each field will present concrete evidence of what can be expected from these products.

•

• Completion of a Navy contract for 40 LST's ten days ahead of schedule was announced by U. S. Steel's American Bridge Co. The record was achieved by Bridge Co.

•

• The Steel Co. of Canada, Ltd., established a new high record for the production of steel ingots in 1943. Notwithstanding increased steel production, sales in value declined approximately one per cent in comparison with the previous year, due largely to variations in the demands for the wide range of products manufactured and changes in control method which affected, from time to time, the production of different lines. Contraction of production of less essential products, followed later by partial relaxation of controls, did not tend to lessen existing difficulties. The current rate of basic steel production continues slightly under full capacity, and is supported partially by orders originating from mutual aid shipments. The trend of costs continues upwards, being influenced latterly by increases in coal mining wages.

POWER TO LIFT A TANK in the palm of your hand!

★ It weighs less than 4 pounds. It's so compact you can hold it in the palm of your hand. But it delivers enough pressurized power to lift a General Sherman tank. That's the amazing, new PESCO Pressure-Loaded Hydraulic Pump!

Never, until PESCO engineered it for modern aviation, was there so small a pump of equal displacement capable of delivering 3000 p.s.i. Radical improvements in design plus precision manufacture of the highest order are the ingredients.

Through PESCO design, entirely new opportunities are opened up for the more practical and efficient use of hydraulics in your product or plant. And that goes for controlled liquid flow as well as pressurized power. For PESCO's advanced design and performance extends through a complete line of hydraulic, pneumatic, vacuum and fuel pumps and pumping systems. Practically without exception, the precision equipment PESCO makes has been engineered to specifications of performance never dreamed of before modern aviation.

We would welcome the opportunity to tell you of our facilities to engineer PESCO equipment to meet your own specific problem. PESCO Engineering Service is available to you. Just write.

SEND FOR THIS BOOK "Pressurized Power and Controlled Flow by PESCO". This book pictorially tells the story of PESCO equipment, manufacturing facilities and engineering service. A copy will be mailed promptly upon request.

STANDARD CONVEYOR COMPANY is able, through long experience, to specify and build for a diversity of handling needs . . .

A procession of products, of the widest imaginable variety, is pouring off assembly lines today — on time, or ahead of schedule — because Standard Conveyors are helping to channel the flow of production. Whether the rate of manufacture is several hundreds a minute or one an hour, Standard builds the right type of conveying equipment to meet the situation.

The range and versatility of Standard Conveyor equipment is the result of nearly 40 years of close contact with inside-the-plant transportation — in plants large and small, making products as widely diverse as steel or cosmetics. The benefit of this experience is available to you, without obligation.

The counsel of Standard Conveyor engineers is valuable in deciding on the right kind of conveying equipment to "deliver the goods" faster—at lower cost — now or for postwar production. *Write for comprehensive reference book — "Conveyors by Standard"—Catalog No. 1A-2.*

Sales and Service in Principal Cities

ENGINEERED FOR FASTER PRODUCTION

jor Eastern aircraft firms has been announced at New York. Delmar Anderson, superintendent of production planning and tool design for the Buffalo plants of Curtiss-Wright Corp., was elected president. Thomas A. Herbert of Consolidated-Vultee is vice-president, Harry W. Tomkins of the Buffalo plants of Curtiss-Wright is secretary, and Charles H. Miller of Bell Aircraft is treasurer.

•

• The Society of Automotive Engineers has organized an Air Transport Engineering Activity Committee to facilitate cooperative solution of engineering problems arising in air line operations. William Littlewood, engineering vice-president of American Airlines, Inc., Jackson Heights, L. I., is chairman.

•

• While Canadian farm machinery production this year is still governed by manufacturing restrictions, certain types of equipment are being speeded up on the assembly line and will be in good supply by the spring and be available for seasonal requirements. Total equipment supplies for 1944 will be 80 per cent of the 1940 figure, with repair parts totalling 156 per cent of that year's tonnage. There is no lack of factory capacity, but there are lacks of materials and manpower. Because of military requirements, we will still face restriction problems in motors, ball-bearings, and malleable castings. Canada imports 70,000 tons of farm equipment from the United States this year and that 50,000 tons of this will be tractors.

•

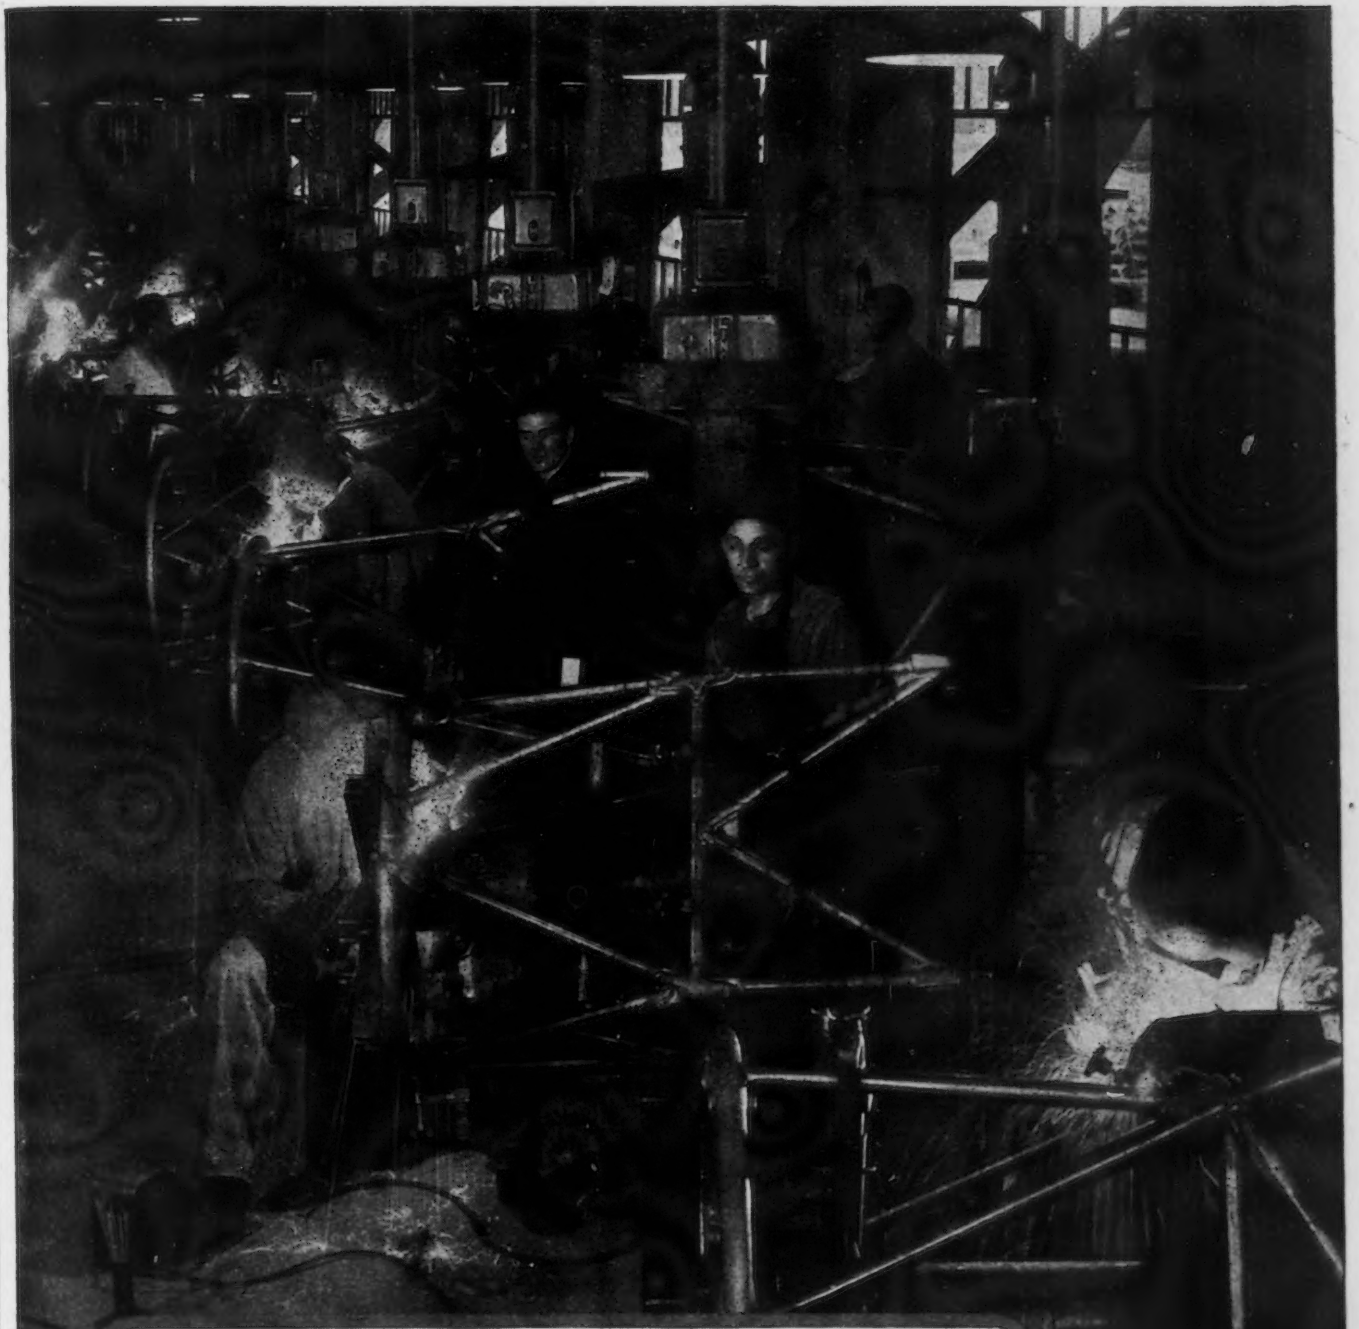
• U. S. Rubber Co. announced the development of multipore, a filter material containing as many as 6400 perforations to the square inch, which is now being used by chemical plants, food factories, medical manufacturers, coal and iron mines, steel mills, liquor distillers, and many other types of industry. These filter screens are made of either hard or soft rubber, and may be compounded to resist abrasion, high temperatures, alkaline and acid solutions, as well as certain oils and greases.

•

• Five members of the machinery fraternity in the Cincinnati area were honored by the Ordnance Department of the U. S. Army recently, for outstanding service in the production of machine tools during the critical period of the machine tool shortage. W. W. Radcliffe, president of the E. A. Kinsey Co., and E. C. Elstad, president of the Seifreat-Elstad Machinery Co., were given citations. Letters of commendation were given to J. F. Jewett, J. C. Mullen, and Arthur C. Pletz. The awards were given to these men by Col. J. C. Schoublin, chief, Cincinnati Ordnance District, at a special ceremony Jan. 31, in recognition of the work done by these men, who are members of the Cincinnati Ordnance District Machine Tool Panel.

•

• Trico Products, Inc., at Buffalo, has applied for permission to convert automatic screw machines used in making 20-mm. projectiles to the production of other munitions. Production of all 20-mm. ammunition has been discontinued at Trico, according to Col. Frank J. Atwood, chief of the Rochester Ordnance District.



MASS-PRODUCTION WELDING

● Time-saving, money-saving mass-production methods are employed throughout our manufacture of welded steel tube, tubular parts and assemblies for the transportation industry. Notable are *double* fixtures for the final welding of bomber motor mounts. Your jobs benefit by these advanced methods.

Among the Week's Trade Notes

Nash Motors Division of Nash-Kelvinator Corp. has purchased a tract of land in Walworth County, Wis., for a postwar automobile proving ground.

●

Western Electric Co., Inc., has leased Area 2 of the Eau Claire Ordnance Plant at Eau Claire, Wis., formerly engaged in arms production. The move was made to take care of expanding production of the company.

●

Lincoln Park Tool and Gage Co. has changed its name to Lincoln Park Industries, Inc. The management, personnel and policies of the company remain unchanged. At the same time the merger of Carbur, Inc., with Lincoln Park was announced.

●

Steel Ingot Production, Inc., New York, has announced the appointment of A. B. Agnew, 4 Smithfield Street, Pittsburgh 22, as sales agent for its "SP" Ingot Mold Insulation.

●

Pennsylvania Salt Mfg. Co. has moved its New York office to 40 West 40th Street.

●

Wyman-Gordon Co., Worcester, Mass., has just installed a new 120-ton anvil base for a 20,000-lb. hammer. The base is 8 ft. high, 10 ft. long and 6 ft. wide, and will be used as a spare. The company is making aircraft crank cases and crank shafts.

●

Heald Machine Co., Worcester, has given Worcester Polytechnic Institute $25,000 to establish a James Nichols Heald research fund, honoring the company's founder, a Tech graduate in 1884.

●

Casco Shipbuilding Co., Freeport, Me., has been liquidated.

●

King Tap & Tool Co., Inc., 84 Chestnut St., North Attleboro, Mass., is being liquidated. All machine tools offered for sale were purchased new in 1941-1942-1943.

●

Joseph T. Ryerson & Son, Inc., has purchased Bethlehem Steel Co.'s Pittsburgh steel warehouse plant, located in Carnegie, Pa. Ryerson has also opened a sales office in the Grant Building, 330 Grant Street, Pittsburgh 19.

●

Rice Lake Engineering Works, Inc., has been organized at Rice Lake, Wis., to conduct a general machine shop business by William A. Cameron, Marie Alnes and Marion McCuskey.

●

Wesley Heat Treating Co., Manitowoc, Wis., has doubled its capital stock to $100,000 and will move its general office from Green Bay to Manitowoc.

●

Dixie Metal Products Co., Bessemer, Ala., formerly owned by the Bessemer Coal, Iron & Land Co., has been sold to three Birmingham men who have formed a new corporation under the name of the Dixie Metal Products Co., Inc.

●

Meriam Co., Cleveland, Ohio, has changed its name to Meriam Instrument Co. Management remains the same.

●

Progressive Welder Co., Detroit, has opened a factory branch office at 1007 Broxton Avenue, Room 222, Los Angeles 24. Howard Dally and A. N. Seedorf are the local field engineers at the new branch.

●

Davison Chemical Corp., Baltimore, has announced the formation of the Process Division with E. B. Dunkak as manager.

●

H. M. Harper Co. has appointed Harris B. Carlock, 1329 North Highland Avenue, N. E., Atlanta, as its representative in that section of the country.

●

William H. Keller, Inc., Grand Haven, Mich., has changed its name to Keller Tool Co. There is no change in personnel or management.

FARVAL—

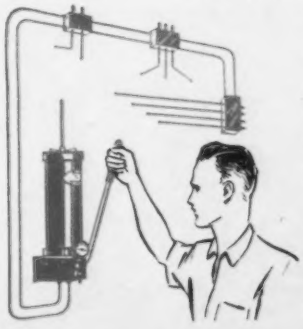
the Safe, Sure Way

from HERE to THERE

THE Farval Centralized System—typified by the genial little tyke who makes "special deliveries" right on the dot—feeds lubricant under hydraulic pressure to each bearing in the exact amounts required.

Whether your equipment is new or old—whether bearings are at floor level or high out of reach—the Farval System measures the lubricant required by each and delivers the correct amount at regular intervals, missing none.

This is no day for guesswork on anything—lubrication least of all. Farval will insure your present production against shut-downs caused by faulty lubrication—will help keep your peacetime equipment rolling on 24-hour schedules too.



Lubricate *your* bearings the Safe, Sure Way and you will save Time—save Men—save Power—save Lubricant—Increase your Production.

Farvalize in '44!

Defense Plant Corp. Contract Award

• • • Defense Plant Corp., RFC subsidiary, has authorized the following contracts:

Boeing Aircraft Co., Seattle, Wash., to provide additional plant facilities in Renton, at a cost in excess of $2,500,000, making a total commitment of more than $21,700,000.

Reynolds Metals Co., Richmond, to provide additional facilities at a plant in Louisville, Ky., at a cost in excess of $600,000, making a total commitment of more than $2,500,000.

Pittsburgh Equitable Meter Co., Pittsburgh, to provide additional machinery and equipment at a plant in Oakland, Cal., at a cost in excess of $75,000, making a total commitment of more than $500,000.

Precision Castings Co., Syracuse, N. Y., to provide plant facilities at Fayetteville, at a cost in excess of $425,000.

Tyson Roller Bearing Corp., Massillon, Ohio, to provide additional equipment at a plant in Massillon, at a cost in excess of $100,000, making a total commitment of more than $400,000.

Carworth Farms, Inc., New City, N. Y., to provide additional plant facilities in New City, at a cost in excess of $60,000, making a total commitment of more than $145,000.

Silica Products, Oregon, Ltd., Eugene, Ore., to provide plant facilities at Eugene, at a cost in excess of $60,000.

American Viscose Corp., Wilmington, Del., for the acquisition of machinery and equipment for a plant in Front Royal, Va., at a cost in excess of $5,000,000.

McCrossin Engineering Co., New York, to provide plant facilities at Rusk, Tex., at a cost in excess of $2,500,000.

Frank Foundries Corp., Moline, Ill., to provide facilities at a plant in Muncie, Ind., at a cost in excess of $95,000.

Sprout & Davis, Inc., Whiting, Ind., to provide automotive equipment at a cost in excess of $30,000.

Lockheed Aircraft Corp., Burbank, Cal., to provide additional plant facilities at Burbank at a cost in excess of $370,000, making a total commitment of more than $8,000,000.

Packard Motor Car Co., Detroit, to provide additional equipment at a plant in Detroit at a cost in excess of $635,000, making a total commitment of more than $3,285,000.

General Electric Co., Schenectady, N. Y., to provide equipment at a plant in Bridgeport, Conn., at a cost in excess of $220,000.

Green River Distilling Co., Stamping Ground, Ky., to provide facilities at a plant at Stamping Ground at a cost in excess of $160,000.

Pascagoula Ice & Coal Co., Pascagoula, Miss., to provide equipment at a plant in Pascagoula at a cost in excess of $110,000.

Pennsylvania Salt Mfg. Co., Philadelphia, to provide equipment at a plant in Philadelphia at a cost in excess of $40,000.

PLOUGHSHARE AND SWORD

★ Udylite war production equipment requires no major conversion to meet the demands of peacetime use.

True, metal finishing requirements will change. New cycles will be required. New products will demand new handling but through it all your basic metal finishing tools will not change—the faithful "swords" of war will become the "plowshares" of peace.

Udylite metal finishing equipment has proved its worth under the strain of wartime performance, the same engineering and dependable quality which enabled it to withstand the rigors of forced production will make Udylite equipment doubly valuable in normal times.

Udylite's staff of experienced engineers offer you the country's most complete line of dependable polishing, plating and anodizing equipment backed by their years of technical "know how". Start RIGHT with Udylite equipment.

Call or write Udylite for your Metal Finishing requirements.

THE UDYLITE CORPORATION

1651 E. Grand Blvd., Detroit 11, Mich.

Continuous Casting

(CONTINUED FROM PAGE 65)

& Iron Co. The Williams patents (1,793,268; 2,206,888; 2,079,644, and 2,187,720) are concerned principally with mold design and methods of mold cooling and lubrication.

When reported on back in 1940, Williams was occasionally casting experimental heats of steel in 4 x 4-in. cross-section at speeds of about 8 ft. per min. It is rather obvious that to continuously cast molten steel at any worthwhile speed, the heat exchange between the mold wall and the coolant must be rapid and accurately controlled. Williams makes his mold of commercially drawn copper or brass tubing of about ¼-in. wall section, which mold is fastened into a very accurately machined cooling chamber. The wall of the heavy steel cooling chamber is only separated from the inner mold wall by a fraction of an inch, and a multitude of flutings in the cooling chamber press against the mold wall keeping it in shape and directing a very high pressure water flow along the mold wall to rapidly scour the heat away.

The Williams mold does not move. As the billet or ingot emerges from the bottom it passes through a series of sizing rolls that prevent bulging of the walls by ferrostatic pressure from the molten interior. Water sprays surround these sizing rolls and the ingot is quite cool when it gets down to a set of pinch rolls which withdraws the ingot from the mold. Mold lubrication is frequently used, and this is automatically introduced around the edge of the molten metal pool by a multitude of orifices, the volume of lubrication being controlled by the speed of the pinch rolls withdrawing the billet.

About a year ago, the Williams process was taken over by the Republic Steel Corp. for extensive experimental investigation at the Cleveland Corrigan-McKinney plant. So far the original Williams molds have been used, but a much larger associated structure has been devised to permit casting of quite long billets. A drawing of this structure and a superimposed picture of the mold section is shown on page 58. It will be seen from the drawing that facilities have been incorporated permitting the bringing of a sizable volume of molten steel (6 tons) in a ladle directly from the open hearth floor, elevating this ladle to the top of the structure for pouring theough the Williams

Production Records ARE BEING MADE WITH

H-W ELECTRIC STEEL FURNACE REFRACTORIES

FOR BASIC PRACTICE

- Star Silica Roofs
- H-W Improved Metalkase Sidewalls
- H-W Magnamix Bottoms

FOR ACID PRACTICE

- Star Silica Roofs
- Star Silica Sidewalls
- H-W Ganister Bottoms

The excellent service secured with STAR silica refractories in the roofs of both acid and basic electric steel furnaces has resulted in their widespread adoption by producers of electric steel. STAR silica refractories are likewise preferred by many operators for sidewalls in acid electric steel furnaces.

The durability of H-W IMPROVED METALKASE linings in basic electric steel furnace sidewalls is reflected in the increased tonnages being produced in the many plants where they are established. A comparison of H-W IMPROVED METALKASE with other refractories in like service, we believe will definitely demonstrate their superiority.

Wherever a trial of H-W MAGNAMIX (a Washington magnesite ramming mixture) has been made in the bottom of basic electric steel furnaces, it has met with instant favor since it has proved to be economical, durable and easily applied.

Prepared by crushing ganister rock (quartzite), H-W GANISTER is established as a material of highest quality for use in the bottoms of acid electric steel furnaces.

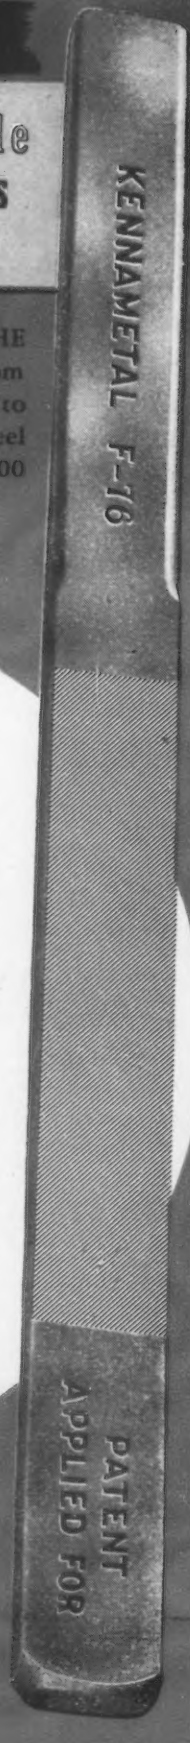
Another KENNAMETAL First!

New KENNAMETAL Lathe File Produces Sensational Results

One KENNAMETAL LATHE FILE removed the burrs from 100,000 shells as compared to 800 to 1,000 shells by a steel file—a production ratio of 100 to one!



Just as the introduction of KENNAMETAL-tipped milling cutters in 1939 is revolutionizing the milling of steel, the NEW KENNAMETAL LATHE FILE promises to establish new standards of efficiency and economy in the filing of steel and other metals. For example . . .

★ KENNAMETAL Lathe Files permit filing speeds of 3 to 10 times that possible with steel files, matching the unusually high cutting speeds of KENNAMETAL carbide tools.

★ KENNAMETAL Lathe Files do not burn up at high speeds but outlast steel files 50 to 200 times.

★ KENNAMETAL Lathe Files cut hardened steels up to 62 Rockwell C which the ordinary file will not touch . . . do a noteworthy job on cast iron and brass at surface speeds around 900 feet per minute, and efficiently file high-carbon, high-chromium steels at 800 surface feet per minute.

At present, KENNAMETAL LATHE FILES are available in one size—Style F-76, illustrated. It is 11" long, ¾" wide, and ¾" thick, having a substantial filing surface 4" long of grade K4H KENNAMETAL (80.6 Rockwell C), single cut with teeth at 30° shear angle, 40 per inch. Shank is shaped for convenient handling.

PRICES
1 to 9 files . . . $15.00 each
10 to 99 files . . . $13.00 each
100 or more . . . $12.50 each
F.O.B. Latrobe, Penna.

FEATURE CONTINUATION

mold. Casts of lengths up to 50 ft. have been made.

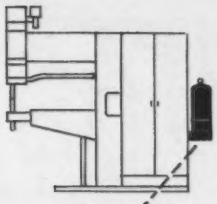
However, experimental data so far from Republic are scanty, as only 40 or so casts have been made, ranging from some very promising metal to worthless casts. These casts all went through a Williams mold essentially the same as that described back in 1940. While the billet lengths are far longer than those produced by Williams at that time, the technique and results otherwise have been little different. None the less, Republic engineers are convinced the operation has possibilities, and have come to some tentative conclusions, subject of course to alteration as experimentation continues.

It is believed that present mold design pretty well limits the casting of, say, a 3 x 8½-in. section at speeds of from 5 to 8 ft. per min. Since faster speeds are desirable some alteration in mold design may have to be evolved, for otherwise a great deal of trouble with bleeding and breakout can be expected. Like previously described in the discussion of the Junghans-Rossi machine, a very critical phase of the operation is that small time interval wherein the ingot shell has frozen and contracted away from the mold wall, but still is not subject to the stringent cooling of the water sprays located below the mold. Several ideas have been developed that may permit drastic cooling to proceed in this zone of operation. Furthermore, the great heat involved has a tendency to result in some mold warping, and here again a change will likely be made to minimize this. It has also been found that the mold wall can be thickened somewhat without interfering appreciably with heat transfer.

Republic is currently constructing new molds of sizes 5 x 10 in. and 6 x 6 in., incorporating therein some of the refinements already discussed. It has been found that 20-gage carbon steel molds work just about as satisfactory as does brass, and a trial with a 24-gage stainless steel mold showed little or no superiority over the carbon steel. It was further found that the mold wall could be ½ in. thick with no appreciable slowing of thermal exchange, although for certain design reasons a thin-walled mold is deemed more desirable.

On several trial runs the steel was poured at near the freezing temperature of 2600 deg. F., and the mold coolant rose about 15 deg. in temperature when circulating at 150 gal. per min. At this rate the water was picking

SCIAKY

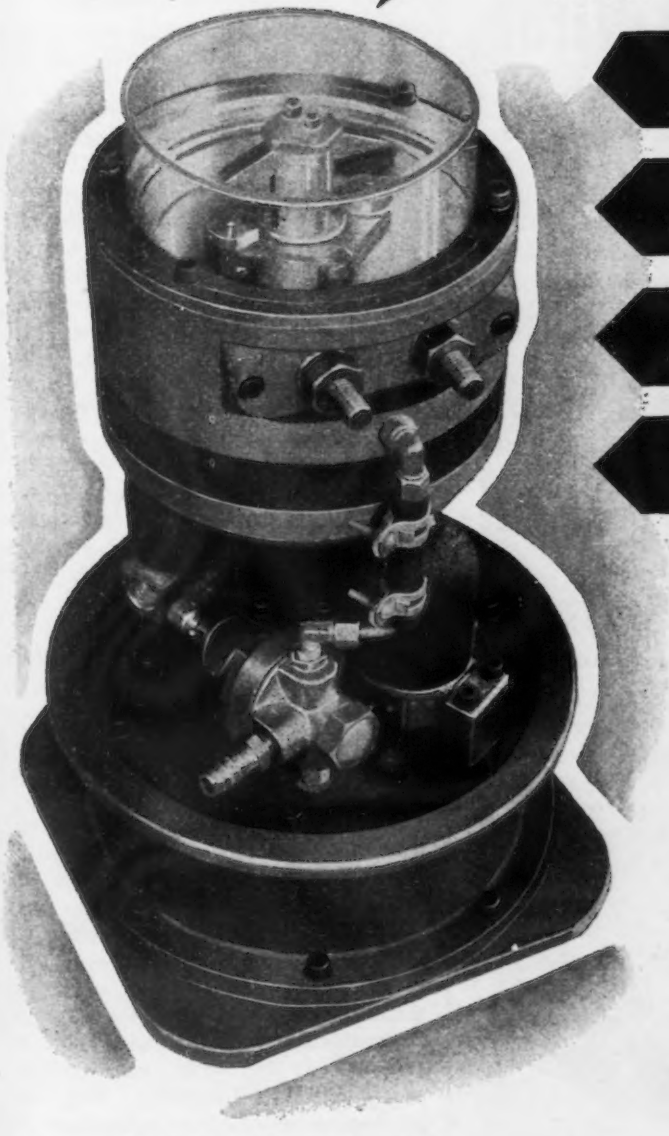


announces a significant achievement in the field of electro-magnetic stored energy resistance welding . . .

a d-c current interruptor — *without arc*

DYNATROL

PATENT PENDING



NO ROUTINE MAINTENANCE REQUIRED

ACCURATE CONTROL OF SECONDARY CIRCUIT DUE TO ABSENCE OF ARCING IN PRIMARY

INCREASED EFFICIENCY OF ELECTRO-MAGNETIC ENERGY SYSTEM — SHORTER CHARGING TIME

SPEED INCREASED 20% OVER MACHINES OPERATING ON CONTACTOR SYSTEM

THE SCIAKY DYNATROL provides the answer to contractor problems on electro-magnetic stored energy resistance welding equipment. This high-speed device performs the function of accurately interrupting the charging current to the reactor *without arc*.

....The problem of interrupting a d.c. current in a highly reactive circuit has always been considered difficult. On former Sciaky machines, this was accomplished by a contactor unit, which together with an arc-blowing device, arc-laminating shields, etc., produced a highly accurate interruption of the charging current.

However, in industrial production, the continuous arcing finally results in a deterioration of the contact tips, requiring periodical maintenance and replacement. It was considered desirable to solve this problem in such a way that the same consistent welds be produced without any maintenance of the interrupting device. To this end, the DYNATROL was developed and was found to be not only a means of more accurate and efficient current interruption, but also, because of the shorter charging time, *actually increases operating speeds 20%*.

The DYNATROL is available on all Sciaky Stored Energy machines up to 50KW.

Three-deck oven showing three REEVES Motodrives

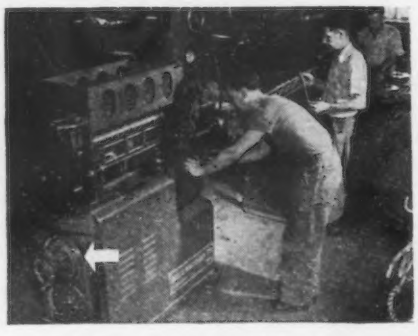
REEVES Speed Control Vital Aid in Welding Rod Production

● The Moslo Machinery Company, Cleveland, Ohio, manufactures a complete line of equipment for producing flux-coated welding rods, and standardly furnishes REEVES Vari-Speed Motodrives on machines in the line to insure fast, uniform high-quality output.

Automatic rod feeder is equipped with a REEVES Motodrive to set feed of electrodes, according to nature of flux and balance of production program. A REEVES Motodrive regulates speed of transfer conveyor to synchronize rod travel from die head with brushing operation, depending on wire size and production schedule. The brushing machine is equipped with a REEVES Motodrive to synchronize its operation with delivery from transfer conveyor and drying rate of oven.

The final operation is drying, and Moslo has developed a special three-deck drier, each deck controlled through a REEVES Motodrive to maintain accurate balance of time, temperature, humidity and flux.

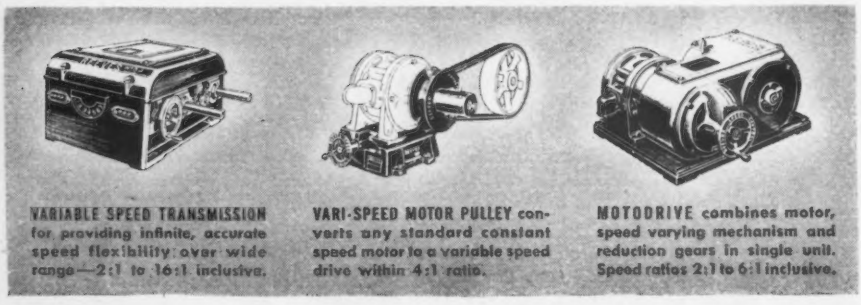
Moslo Machinery Company is only one of thousands of machine builders



REEVES-equipped Automatic Feeder

who furnish REEVES Speed Control as standard equipment to insure most efficient operation under all changing conditions. REEVES units are easily applied to machines in service. Send for copy of catalog I-435 giving complete information on REEVES Variable Speed Drives.

REEVES PULLEY COMPANY • COLUMBUS, INDIANA



VARIABLE SPEED TRANSMISSION for providing infinite, accurate speed flexibility over wide range—2:1 to 16:1 inclusive.

VARI-SPEED MOTOR PULLEY converts any standard constant speed motor to a variable speed drive within 4:1 ratio.

MOTODRIVE combines motor, speed varying mechanism and reduction gears in single unit. Speed ratios 2:1 to 6:1 inclusive.

up about 18,000 B.t.u. in about 6 sq. ft. of mold surface. And, since in the very best of high duty boiler installations of modern Naval design the maximum heat exchange is on the order of 3000 B.t.u. per sq. ft. per min., the opinion was that at the 8 ft. per min. speed the casting of the 3 x 8½ in. section was progressing just about as fast as theoretically possible in order to freeze the entire cross-section to a solid.

In actual practice, however, only the outer skin of the ingot need be frozen in the mold, the interior being solidified as the result of water spraying below the mold. For the 3 x 8½-in. section, a total of, say 10 sq. in. of outer cross-section would be fully sufficient to solidify in the mold. This would permit a *theoretical* casting speed far above the 8 ft. per min. used in the experiment cited above.

Parenthetically, it might be pointed out that when Bethlehem experimented with continuous casting of steel in 1941, somewhat similar conclusions were reached. As seen from the photographs on page 61, the Bethlehem set-up was comparatively simple. The copper mold was water-cooled by means of five sets of copper coils fastened to the outside surface of the mold. Bethlehem cast 4-in. rounds, and made about 30 casts in all. Speeds of 15 ft. per min. were reached, but optimum speed seemed to be 8 to 10 ft. per min. Carbon steels, from 0.1 C to 0.5 C were tried, and thermal cracks were found in all analyses above 0.3 C. In general, the surface condition was poor, with laps, folds and bleeding, as may be seen in the photograph on page 61. The mold itself seemed to stand up well and the coolant showed no large rise in temperature. A secondary cooling spray was located around the bottom of the mold. The experiment, however, was abandoned because of pressure of other work, and not very many definite conclusions were established.

But, all the mold refinements being worked out by Republic, together with some alterations in the handling of coolant to additionally improve the scouring of heat off the interior of the mold wall, may possibly open the way to faster speeds and serve to stabilize the operation considerably, the result being that a year from now this unit can well be of great interest to the entire steel industry. For, like all continuous casting operations it may be a means whereby a relatively small capital expenditure can furnish immediate break-downs for rod and wire mills, and perhaps be a means of

BREECH BLOCKS AND HOUSINGS OF *Barium Steel* PROVIDE THE KICK OFF

Barium Alloy Steel again demonstrates its ability to handle tough assignments.

For the Breech Blocks and Housings of many of the guns in Uncle Sam's Navy are products of Barium's *Unified Control:*

Melted and refined in Barium's furnaces

Forged under Barium's giant presses and hammers

Scientifically heat treated and quenched

Machined in Barium shops

It is *team-work* like this that accounts for Barium success in furnishing hard-to-make ordnance. We invite your inquiries for Die Blocks, Hammer Rods and Heavy Forgings.

locating some small plants in remote areas to handle local requirements and to draw upon surrounding scrap supplies.

Goss Process:

The only other equipment in experimental operation with steel is that designed by Norman P. Goss, of the Cold Metal Process Co., Youngstown, Ohio. This method was just mentioned back in 1940, since at that time it had only been conceived and patented. Subsequently, however, a machine has been built and operated at intervals at the Duluth, Mich., plant of the American Steel & Wire Co. Conscious of the concern of Junghans-Rossi and Williams with the need for uninterrupted cooling of the ingot during that short interval after the skin is formed and pulls away from the mold wall, Goss in his patent (2,-225,373) provides for a mold made up of numerous sections, each section individually cooled. Particularly interesting is the means provided whereby as the metal skin freezes and pulls away from the mold wall a finely divided solid material is introduced through many orifices in the mold wall. This material is capable of remaining solid during the casting operation and also capable of accommodating itself to the interstices between the cast metal and die wall. In this manner the walls of the die are protected from abrasion and galling, and the congealing metal is also protected from run-outs and abrasion. This material also maintains a heat-conducting contact between the ingot skin and the die wall.

The Goss method also provides for sealing off the top of the mold and introducing above the metal pool an inert or reducing gas to prevent metal oxidation, and also under sufficient pressure to create considerable hydrostatic pressure, if so desired. Below, the mold, as in practically all continuous casting processes, there are provided a number of cooling sprays and a set of pinch rolls to withdraw the ingot from the mold.

Since the Goss method sets up a number of additional variables, such as many different and controllable zones of cooling, the pressure, volume and points of entry of the material to fill up the gap between ingot skin and mold wall, and the amount of gas pressure above the metal pool, it is apparent that many adjustments can be made in speed of casting, in condition of ingot surface, and in metal-

Stearns Suspended MAGNET at DUQUESNE PAYS FOR ITS OPERATION

This 65" Stearns Suspended Circular Magnet above the head pulley of the main belt conveyor at the Warwick mine of Duquesne Light Co. recovers enough scrap metal to pay for its operation.

But—the important feature of this magnet installation is that it protects crushers and other valuable machinery.

You too may have a problem of protection, reclamation or purification that can be efficiently, profitably solved with magnetic equipment. Consult Stearns Magnetic Milwaukee for advice and recommendations.

HOLLY, MICHIGAN

lurgical structure of the steel throughout the cross-section.

In the casts already made it has been determined that the mold is a feasible piece of equipment, that sound metal can be cast at fair speed, and a very smooth ingot skin can be secured. Here again, like the Williams process. The Goss method of casting steel needs considerably more experimental investigation, but can well be a method very much worth watching for the effect it could possibly have on the economics of steel production.

Users of Fork Trucks Queried as to Desires

Chicago

• • • **To guide its** engineers in designing materials handling equipment for postwar manufacture, Clark Tructractor, Battle Creek, Mich., a divition of Clark Equipment Co., has inaugurated a study of customer preferences, similar to those employed by the automobile industry.

A questionnaire has been circulated among industrial concerns to determine their materials handling habits and preferences. Dealing principally with fork trucks, users are asked, with regard to their needs and preferences, such questions as where the driver should be placed, type of power preferred, make of battery for electric trucks, tilting requirements, upright data, tires, ramp climbing ability under full load, underclearance data, speeds, turning radius, weight and width of machine, safety features, and for opinions on other features. The questions are illustrated by small drawings showing the features discussed.

The survey is based on the thesis that the present 30 to 50 per cent of unskilled men in industry must be reduced to 5 or 10 per cent if American industry is to compete with low cost foreign labor and that one of the ways to do this is to substitute efficient materials handling equipment for unskilled workers.

Patent List Omitted

• • • Omitted from this week's magazine are the seized metalworking patents, which have appeared in 15 preceding numbers. Publication will be resumed in an early issue.

. . . News and Market Activities

International Detrola Merger Explained

Elkhart, Ind.

• • • **In a move to diversify** its activities and find new uses for its working capital in the face of a slackening machine tool market, the International Machine Tool Corp., Elkhart, Ind., has acquired Detrola Corp., Detroit, which makes radio and other electronic devices. In explaining the merger, which was effected Dec. 31, 1943, C. Russell Feldmann, president of the new International Detrola Corp., stated that the machine tool firm possessed resources, particularly working capital, upon which it might be difficult to show an adequate return on the machine tool business alone in view of the present trend in sales.

The Detrola Radio Division, which on Dec. 31, 1943, had war contracts totaling about $19,100,000, on the other hand, had lacked adequate capital for expanding war work and to take fullest advantage of the civilian market after the war, Mr. Feldmann said. Civilian radios have not been made since May, 1942. Pre-war products of Detrola included portable and home radios, record changers and automobile radios.

By the addition of consumer goods products, Mr. Feldmann expects International to be able to iron out some of the violent fluctuations in machine tool production. Post-war activity in the radio division should place at the disposal of the corporation funds for research and product development in the machine tool divisions during periods of slack sales when engineering expense is ordinarily curtailed. Several long term projects of this nature have already been planned, one of them stemming from research in surface finishes as a result of the development of superfinishing equipment.

One of the immediate effects of the merger has been the retirement of a $2,400,000 V-loan which had been a Detrola obligation. A V-loan of $5,500,000 of the International Machine Tool Corp. had been paid earlier, leaving the International Detrola Corp. free from all bank indebtedness. International also retired during 1943 the remainder of its outstanding preferred stock.

Mr. Feldmann has been president of both Detrola Corp. and International Machine Tool Corp., as well as being board chairman and principal stockholder of Strong, Carlisle & Hammond Co., distributor of machinery, mill supplies and other items with main offices in Cleveland and a branch in Detroit. Since Dec. 12, 1942, and during 1943, Strong, Carlisle & Hammond acquired practically all of the common stock of Detrola Corp. The Cleveland firm now owns a large block of stock of International Detrola Corp. Capital stock of International Machine Tool Corp. was increased by 152,000 shares to effect the merger, making a total of 490,000 shares outstanding at a par value of $1. A seventh consecutive quarterly dividend of 25c. was recently declared.

Detrola stockholders received one share of International Detrola in exchange for 1.8 shares of Detrola Corp., with International holders retaining their present holdings.

Net sales (unaudited) of Detrola for the 12 months to December 31 were $11,746,248.72 and net profit $522,957.86 after provisions for Federal taxes and an estimated refund to result from renegotiation. Net profits of International for 12 months ending October 31, 1943, were $1,191,517.89 after Federal income taxes and provision for estimated refund to result from renegotiation.

o o o

Tool Redistribution Explained

Cleveland

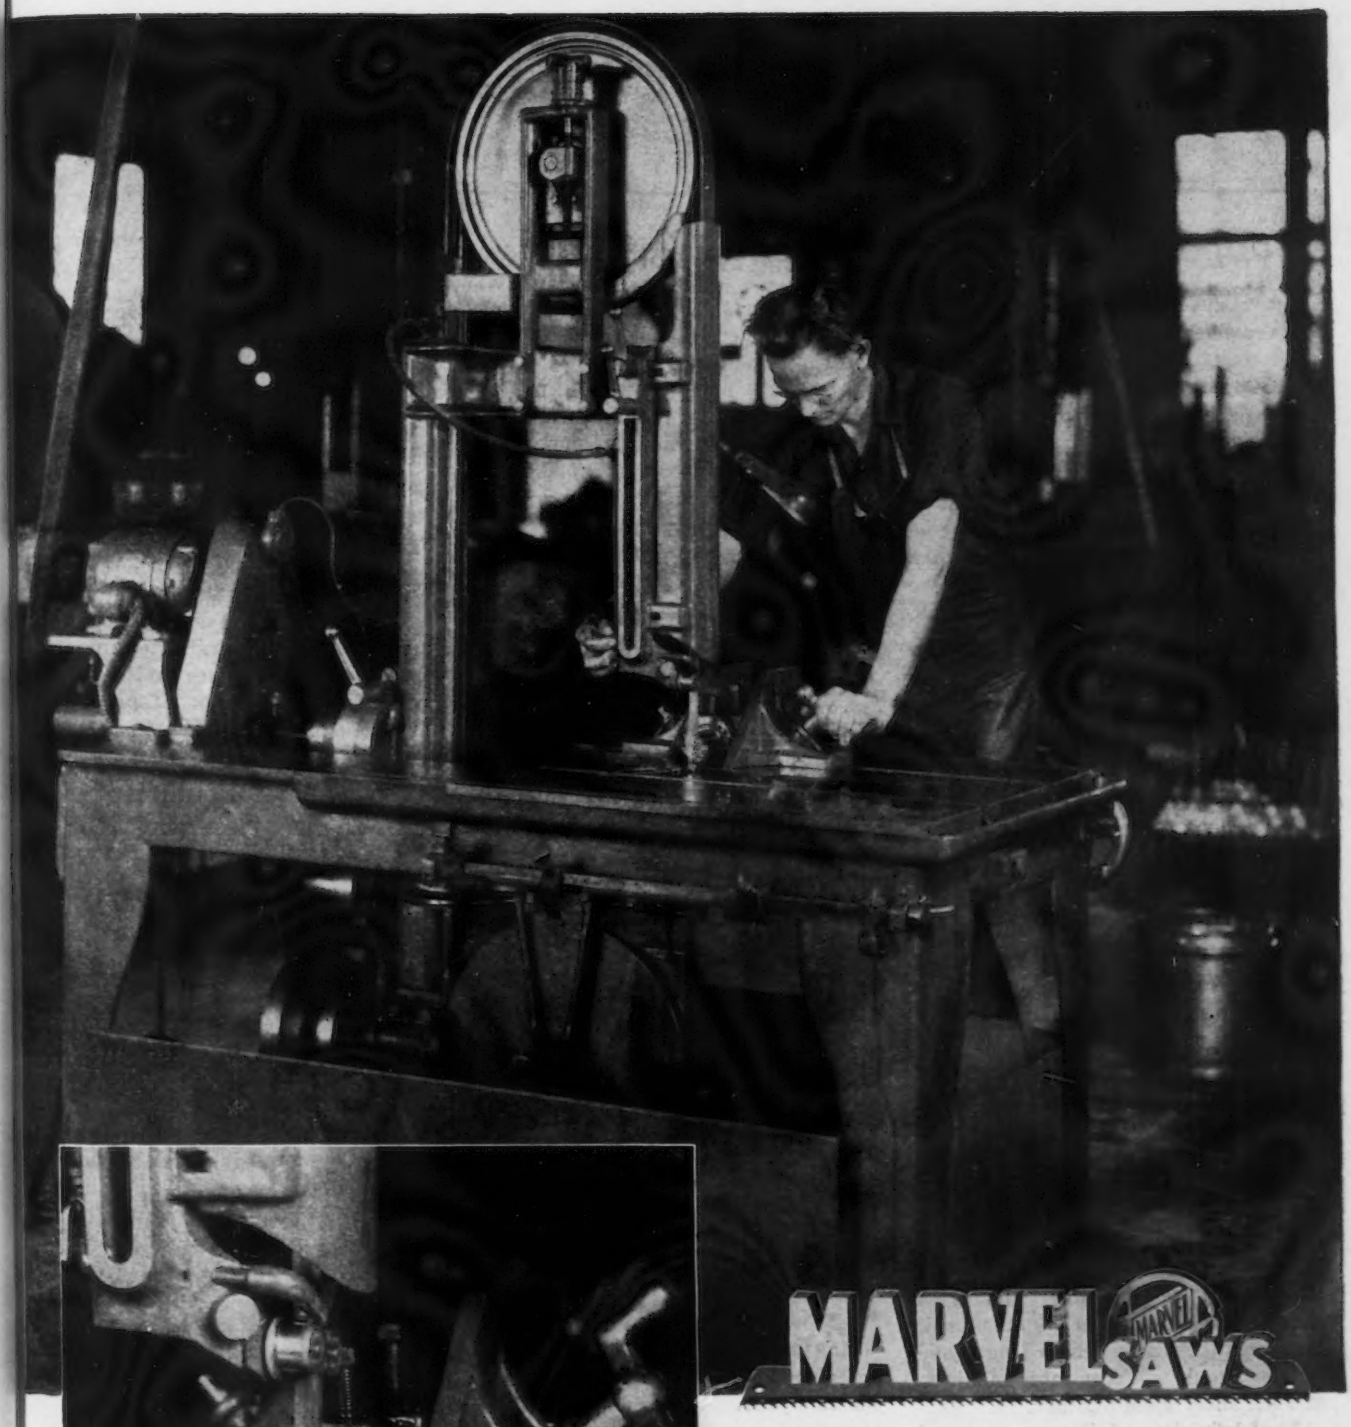
• • • **The local WPB** redistribution department reports January as the largest volume month in the 20 months' existence of this regional office for the referral of machine tools in the idle and excess categories to new war plant or essential civilian users. The dollar value of referrals of machine tools for the month of January totaled $2,057,296 on the basis of OPA used machine prices. These used tools originated from DPC, Army Ordnance, Navy, and both prime and subcontractors as well as second hand machine tool dealers. Listings of idle and excess machine tools on hand at the regional WPB office include a reasonably comprehensive list covering the entire nation, plus voluntary listings from local contractors and government and military agencies in the region.

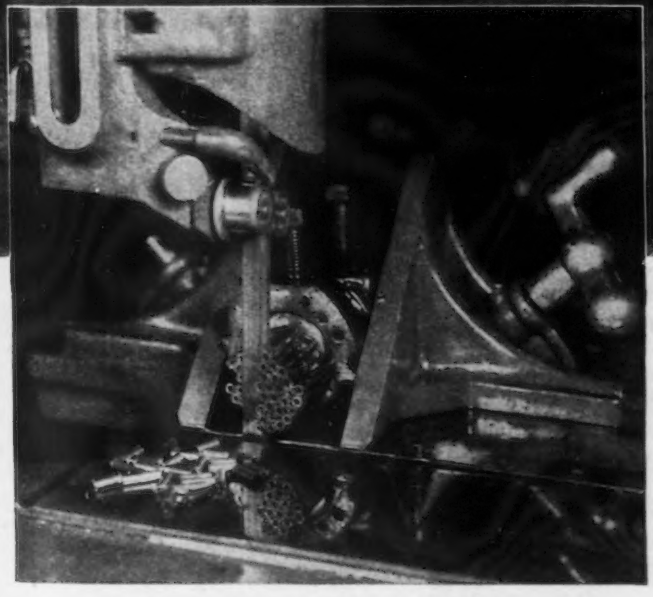
The WPB is reported to have sponsored an order which would make mandatory reporting of all idle and excess machine tools regardless of the holder. This would place all holders under the same restrictions as now govern used machine tool dealers and would serve to give the WPB a complete listing of all tools which might be available and also provide a picture of what the postwar supply of such tools might be. It is believed that issuance of this order is being withheld for inclusion with some over-all plan for the redistribution of tools in the event of serious contract cutbacks and during the postwar era.

The method of applying for tools today falls into roughly two general methods: Should a war plant or essential civilian producer have need for additional equipment, application for a new tool or series of tools can be made on either WPB-541 or 542. This application goes to the district WPB office where it is screened for necessity. During the screening process the possibilities of subcontracting the work rather than supplying a new machine are considered. If this is found to be impossible or unsatisfactory the application goes to the regional office which then offers, if possible, a substitute machine from among the listings of idle and excess machines. If such equipment is found to be satisfactory, a deal is consummated through the actual holder of the machine with the WPB redistribution division acting only as the intermediary.

RFC Loan Plan

• • • **RFC is offering** to loan manufacturers money to cover reconversion costs. RFC Chairman Charles B. Henderson on Feb. 14 made public a letter to the managers of all RFC loan agencies in which he said "the RFC must be prepared to carry out our responsibility to the national economy in the exercise of our statutory lending powers for demobilization, contract termination and reconversion to peacetime operations."





Cutting-off nested small diameter tubing—50 pieces per cut. On production jobs like this, the extreme accuracy and comparatively fine teeth of the blade produce smooth-edge, semi-finished pieces at very low cost.

MARVEL SAWS

"It has increased production about 30%" at Independent Pneumatic Tool Co.

Used to cut off a great variety of stock; cold drawn tubing (2335 S.A.E., 3115 S.A.E., and 3135 S.A.E.), angle iron, and round, hex and square bars in a wide range of sizes, this MARVEL No. 8 Metal-cutting Band Saw "has increased production about 30%" in the cutting-off department of the Independent Pneumatic Tool Co., Chicago.

The most versatile metal-cutting saw built, the MARVEL No. 8 is a truly universal tool. It handles work up to 18" x 18" cross section; cuts at any angle from 45° right to 45° left; does mitering, notching; saves warehouse delays and "cutting extras" and saves hours of machining by roughing work to size and shape.

Copper Requests Show Heavy Demand

• • • **Crude copper production** declined slightly in January, from 98,553 net tons to 96,004 tons, according to the Copper Institute. Refined output also declined 11,863 tons last month to 92,781 tons.

Deliveries to consumers declined from 115,850 tons in December to 101,586 tons in January. However, February and March deliveries will undoubtedly rise again. March requests for copper have been quite large as inventories which were permitted to drop to unhealthy levels are rebuilt.

Although the government agencies are reluctant to admit openly that copper cannot now be considered in the scarcity group, there has been some lifting on use restrictions. With the revocation of L-106, virtual freedom was given for the use of copper and copper base alloys for the civilian production of automobile radiators, gaskets, fuel and oil lines, brake and clutching lining rivets, and other essential parts that formerly incorporated copper in their composition. During the copper shortage these parts were made of substitute materials. Revocation of the order, however, does not permit the manufacture of any products with copper other than those specifically enumerated in L-158, which remains in force, and prohibits the use of copper and copper base alloys for decorative or other non-essential parts. Also remaining in force is conservation order M-9-c, which prohibits the use of these metals whenever substitution of a more plentiful material is practicable.

The revocation of L-106 will result in making available approximately 5,000,000 lb. of copper per quarter for the parts specified in L-158. The return to use of the more familiar material will also mean, it is estimated by industry, more satisfactory products, and considerable savings in manhours of labor for production, maintenance and installation of these parts in civilian cars.

Copper Sheet Redefined

• • • **The definition** of an item of brass mill product, used in rules governing warehouse deliveries of such items, has been modified to indicate that difference in temper will differentiate one item of copper and brass sheet from another, WPB announced last week. Formerly, both length and temper would differentiate one item of such sheet from another.

The definition of items, contained in CMP Regulation 4, dealing with sales of controlled materials by warehouses, governs amounts of specific controlled materials forms and shapes of brass mill products that can be delivered by a warehouse. Limitations on deliveries are on an item basis, and as a result, the definition has a direct bearing on deliverable amounts.

•

Canadian Output Earmarked

Toronto

• • • **No difficulty** is expected in disposing of all the refined copper, lead and zinc that can be produced in Canada this year. All surplus production of refined copper and zinc, in excess of domestic requirements, is under contract to be sold to the United Kingdom. Although the supply position is easier in these two metals, the general expectation in the industry is that contracts will not be disturbed. Lead was not covered in the original war contracts, but the outlook is that it too will continue to be readily marketable. The position with respect to zinc concentrates is more obscure at the moment. Output of zinc concentrates is largely if not entirely under contract to the United States. This production, therefore, is more sensitive to the mounting surplus of metal stocks in that country. Metal consumption is divided into three classes for priority purposes: War uses, essential civilian uses and non-essential civilian uses. Supply is gradually becoming available for non-essential civilian uses and a gradual progressive relaxation of present restrictions may be expected as the year goes on.

•

Schedule Corrections

Washington

• • • **The portion of** schedule III of CMP Regulation No. 1 dealing with the time for placement of authorized controlled material orders for copper and aluminum was inadvertently omitted from the regulation revision on Feb. 2. Schedule III indicates the number of days in advance of the first day of the month in which delivery of controlled materials is required that orders must be placed with producers.

As a result of the omission, it has been necessary to insert the portion of the schedule dealing with copper and aluminum in the regulation by Amendment No. 1. There have been no changes in the number of days indicated in each case.

	Days Prior to First of Month in Which Shipment Is Required
Brass mill copper and copper base alloy products:	
Copper and non-refractory alloys	45
Refractory alloys	60
Wire and cable products:	
Bare wire and cable	35
Weatherproof wire and cable	35
Magnet wire	35
Rubber insulated building wire	35
Paper and lead cable	40
Varnished cambric cable	35
Asbestos cable (type H-F)	60
Rubber insulated wire and cable (mold or lead cured)	45
Foundry copper and copper base alloy products:	
Castings (rough castings, not machined—assuming patterns are available)	
Small simple castings to fit 12 x 16 in. flask	7
Large intricate and centrifugal castings	14
Aluminum, all forms and shapes	45

SALES REGULATIONS: On and after March 15, 1944, no operating railroad not operating in a basing point named may sell or offer for sale iron and steel scrap to a consumer or his broker without obtaining prior written approval from OPA unless prior to that date it has filed with OPA a statement in writing setting forth maximum on-line price for No. 1 Railroad Heavy Melting Steel and describing the method used to calculate this price. The statement shall include: The most favorable basing point selected; the price at such basing point; the location of the scrap accumulation point; the lowest established charge for transporting scrap by rail from such accumulation point to the named basing point; and the foreign line proportion of such lowest established charge.

MAXIMUM PRICES: The maximum on-line price of any grade of steel scrap from an operating railroad operating in a basing point shall be the price set for the scrap at the highest priced basing point in which the railroad operates. For an operating railroad not operating in a basing point, the price shall be the price set for the scrap at the most favorable basing point less the foreign line proportion of the lowest charge for transporting scrap by rail from scrap accumulating point of railroad to such basing point. "Scrap accumulation point" is that point from which greatest tonnage was shipped in 1943. "Most favorable basing point" that the basing point which will yield the highest maximum on-line price. In no case need the on-line maximum price fall below $15.00 per gross ton for No. 1 Railroad Heavy Melting Steel. The maximum price of any grade of steel scrap originating from a non-operating railroad shall be the price established for the scrap at the most favorable basing point minus the transportation charges for rail, vessel, or motor vehicle shipment or combinations of these, and for established charges shown in OPA Price Schedule No. 4. Where the non-operating railroad is located in a basing point shown above, the following switching charge deductions will be applicable: Chicago—84c.; Pittsburgh—55c.; Detroit—53c.; Cleveland, Los Angeles, San Francisco, Sharon, and Youngstown—42c.; Seattle—38c.; Buffalo—36c.; Birmingham and Kansas City—32c.; Ashland, Canton, Cincinnati, Duluth, Kokomo, Portsmouth, Steubenville, St. Louis, Wheeling, and Wilmington—28c.; Middletown and Philadelphia—14c.; and Sparrows Point—11c.

SCRAP PREPARATION: With the exception of unprepared scrap prepared in-transit, railroad steel scrap prepared by a dealer or moving through a dealer's yard shall be deemed to have lost its railroad origin, and shall be classified and priced as steel scrap other than railroad scrap except in specified grades peculiar to railroad origin (listed in the schedule). For these listed grades the maximum shipping point and delivered prices shall be the same as those established for non-operating railroads for those grades. The maximum shipping point price of any grade of railroad cast iron scrap sold by a dealer shall be the same as that established for the railroad seller. "Unprepared scrap" shall have its customary trade meaning and shall not include such demolition projects as bridges or box cars which must be so priced that the prepared scrap will deliver to the consumer within the maximum delivered price established.

PREPARATION CHARGES: If unprepared scrap is purchased from an originating railroad, the consumer may designate a dealer to prepare such scrap on a preparation fee basis. The maximum preparation fee shall be the established differentials between the unprepared scrap and the listed grade for which the scrap is prepared. For example: $3.50 per gross ton for prepared No. 1 Railroad Heavy Melting Steel from Structural and/or Wrought Iron and Steel Uncut; or $2.50 for cutting rails 18-in. and under from Scrap Rails of Random Lengths; or $4.00 per ton for No. 2 Bundles prepared from No. 1 Sheet Scrap. For cast, an in-transit preparation fee will be applicable only for preparing Cast Iron No. 3 into Cast Iron No. 1, for which the maximum preparation fee shall be $3.50 per gross ton. (Previous dealer fee was $2.50.)

MAXIMUM PRICE ON PREPARED SCRAP: The maximum delivered price for railroad scrap prepared in-transit shall be the maximum on-line price for the unprepared scrap, plus the applicable rail transportation charges incurred in moving scrap to dealer's yard, plus the applicable preparation fee, plus transportation charges from the dealer's yard to point of delivery.

Cast Iron Scrap

Maximum on-line price, per gross ton, for any of the following cast grades will be the price shown at the highest priced zone in which the railroad operates or is located.

	Per Gross Ton		
	Zone A	Zone B	Zone C
Cast Iron, No. 1	$18.00	$19.00	$20.00
Cast Iron, No. 2	17.00	18.00	19.00
Cast Iron, No. 3	14.50	15.50	16.50
Cast Iron, No. 4	13.25	14.25	15.25
Cast Iron Brake Shoes	13.25	14.25	15.25
Malleable	20.00	21.00	22.00
Wheels, No. 1	18.00	19.00	20.00

Zone A includes Mont., Idaho, Wyo., Nev., Utah, Ariz., and N. M. Zone B includes N. D., S. D., Neb., Colo., Kan., Okla., Texas, and Fla. Zone C includes all states not named in zones A and B, and includes switching district of Kansas City, Kansas-Missouri.

CAST IRON GRADE DEFINITIONS: Cast Iron, No. 1—Cast iron scrap such as columns, pipe, plates and/or castings of miscellaneous nature, but free from stove plate, brake shoes, and/or burnt scrap. Must be cupola size not over 24 x 30 in. and no pieces to weigh more than 150 lb. Free of foreign material. No. 2—Cast iron scrap in pieces weighing over 150 lb. not more than 500 lb. and free from burnt cast. No. 3—Cast iron scrap in pieces over 500 lb., includes cylinders, driving wheel centers, and/or all other castings. Free from hammer blocks or bases. No. 4—Burnt cast iron scrap such as grate bars, stove parts, and/or miscellaneous burnt scrap. No. 5—Driving and/or car brake shoes of all types except composition filled. Malleable—Malleable parts of automobiles, railroad cars, and locomotives. No. 7—Wheels, No. 1, includes cast iron car and/or locomotive wheels.

* Baled turnings are $5 per gross ton higher.

BUNDLES: Tin can bundles are $4 below dealers' No. 2 bundles; No. 3 bundles are $2 less than No. 1 heavy melting.

AT NEW YORK CITY or Brooklyn, the maximum shipping point price is $15.33 for No. 1 heavy melting, f.o.b. cars, f.a.s. vessel or loaded on truck. Minimum set at $14 per gross ton at any shipping point in U. S. Other grades carry differentials similar to those in table. New Jersey prices must be computed on basis of all-rail. At Boston the maximum is $15.05 for No. 1 f.o.b. cars, f.a.s. vessel or loaded on trucks. Shipments from a New England shipping point to a consumer outside New England carry maximum transportation charge of $6.66 per ton.

SWITCHING CHARGES: Deductions for shipping points within basing point (cents per gross ton) are: Chicago, 84c.; Pittsburgh, Brackenridge, 55c.; Detroit, 53c.; Midland, Johnstown, Sharon, Youngstown, Warren, Weirton, Cleveland, Toledo, Los Angeles, San Francisco, Pittsburg, 42c.; Seattle, 38c.; Buffalo, Claymont, Harrisburg, 36c.; Atlanta, Birmingham, 32c.; Butler, Monessen, Canton, Steubenville, Cincinnati*, Portsmouth, Ashland, Coatesville, Phoenixville, Bethlehem, Kokomo, Duluth and St. Louis, 28c.; Alabama City, Ala., 26c.; Minnequa, Colo., 22c.; Middletown, 14c.; Conshohocken, Sparrows Point, 11c.

*Basic open hearth and foundry grades, and auto springs and crankshafts, deduct 80c. per ton.

BASING POINT includes switching districts of city named.

Basing point	Switching districts:
Pittsburgh	Bessemer, Homestead, Duquesne, Munhall, McKeesport
Cincinnati	Newport
St. Louis	Granite City, E. St. Louis, Madison, Ill.
Chicago	Gary
Claymont	Chester, Pa.
San Francisco	So. San Francisco, Niles, Oakland

MAXIMUM SHIPPING POINT PRICE: Where shipment is wholly or partially by rail or vessel, or combination of rail and vessel, the scrap is at shipping point when placed f.o.b. railroad or f.a.s. vessel. For motor vehicle shipments scrap is at shipping point when loaded. Then maximum shipping point price shall be: (a) For shipping point located within a basing point, prices shown in above table for scrap at basing point in which shipping point is located, minus applicable switching charge deduction shown in paragraph above labeled **"Switching Charges."** (b) For shipping points outside basing point, price listed in above table hereof for scrap at most favorable basing point, minus lowest charge for transportation from shipping point to such basing point by rail or water carrier or combination. Where vessel movement is involved, in lieu of established dock charge or any cost customarily incurred at the dock, 75c. per ton must be included as part of deduction in computing shipping point price; 50c. at Memphis; $1 at Great Lakes ports; and $1.25 at New England ports. If no established transportation rate exists for a portion of movement from shipping to basing point, actual charge or cost customarily incurred by shipper in such portion of movement shall be included as part of deduction in computing shipping point price. For exceptions see official order.

UNPREPARED SCRAP: For unprepared scrap, maximum prices shall be $3.50 (and in the case of the material from which No. 1, No. 2, and No. 3 bundles are made $4) less maximum prices for the corresponding prepared scrap. In no case, however, shall electric furnace, acid open hearth and foundry grades be used as the corresponding prepared scrap. A preparation-in-transit charge for unprepared scrap is provided.

NEW LISTED GRADES: Priced in dollars per gross ton less than No. 1 heavy melting steel. Pit scrap, ladle skulls, slag reclaim, etc., of 85% or more Fe priced less $2; 75 to 85% Fe less $4; under 75% Fe less $8 per ton. Mill scale less $8 per ton. Mill cinder and grindings, shipping point maximum price of $4 per gross ton at all U. S. shipping points.

CHEMICAL BORINGS: No. 1 (new, clean, containing not more than 1% oil), $1 less than No. 1 heavy melting; No. 2 (new, clean, containing not more than 1.5% oil), $2 less than No. 1 heavy melting. If loaded in box cars add 75c. mill scale, $8 less than No. 1 heavy melting.

Tool Steel Scrap Prices (MPR 379)

	SEGREGATED Solids Per Lb. Cont. W	SEGREGATED Turnings Per Lb. Cont. W
Type 1. 12% min. W, 1% max. Mo	$1.80	$1.60
Type 2. 5 to 12% W, 1% max. Mo	1.60	1.40
Type 3. 1 to 5% W, 1.5% max. Mo	1.25	1.25
*Type 4. 7% min. Mo, 2% max. W	0.125	0.105
*Type 5. 3.5 to 6% Mo, 4.5 to 6% W	0.135	0.115

UNSEGREGATED SOLIDS
$1.50 per lb. contained W if 5% or more.
$1.15 per lb. contained W if 1 to 5%.
$0.80 per lb. contained Mo if 1.5% or more.

UNSEGREGATED TURNINGS
$1.30 per lb. contained W if 5% or more.
$1.00 per lb. contained W if 1 to 5%.
$0.70 per lb. contained Mo if 1.5% or more.

If both W and Mo are within ranges, payment may be for both W and Mo content.

*Per lb. of scrap material.
If segregated, a premium of $1.50 per lb. of contained Co allowed if Co content is 3% or over. No scrap considered segregated if Co content ranges between 0.5 and 3%.
If Cu or Ni content over 0.25%, price shall be reduced by 50%.
If 500 lb. or less is sold, either segregated or unsegregated, price shall be reduced 2c. per lb. of scrap material.

Revised price schedules, establishing dollars and cents differentials for railroad scrap and establishing revisions in cast iron scrap grades are shown on page 158. These schedules, amendment 14 to RPS No. 4, replace the previous schedules on Railroad Steel Scrap and Cast Iron Scrap sold by railroads.

The various basing points for finished and semi-finished steel are listed in the detailed price tables, pages 157-169.

Composite Prices . . .

Starting with the issue of April 22, 1943, the weighted finished steel price index was revised for the years 1941, 1942 and 1943. See explanation of the change on page 90 of the April 22, 1943, issue.

Weighted index based on steel bars, beams, tank plates, wire, rails, black pipe, hot and cold-rolled sheets and strip, representing 78 per cent of the United States output. Index recapitulated in Aug. 28, 1941, issue.

Based on averages for basic iron at Valley furnaces and foundry iron at Chicago, Philadelphia, Buffalo, Valley and Southern iron at Cincinnati.

Based on No. 1 heavy melting steel scrap quotations to consumers at Pittsburgh, Philadelphia and Chicago.

. . . Prices of Finished Iron and Steel

Steel prices shown here are f.o.b. basing points, in cents per lb., unless otherwise indicated. Extras apply. Delivered prices do not reflect 3% tax on freight. (1) Mill run sheet, 10c. per 100 lb. under base; primes 25c. above base. (2) Unassorted 8-lb. coating. (3) Widths up to 12-in. (4) 0.25 carbon and less. (5) Applies to certain width and length limitations. (6) For merchant trade. (7) For straight length material only from producer to consumer. Discount of 25c. per 100 lb. to fabricators. (8) Also shafting. For quantities of 20,000 to 29,999 lb. (9) Carload lot in manufacturing trade. (10) Prices do not apply if rail and water is used. (12) Boxed. (13) Portland and Seattle price, San Francisco 2.50c. (14) This base price to be used in figuring annealed, bright finish wires, commercial spring wire.

EXCEPTIONS TO PRICE SCHED. NO. 6

Slabs—Andrews Steel Co. $41 basing pts.; Wheeling Steel Corp. $34 Portsmouth, Ohio; Empire Sheet & Tin Plate Corp. $41; Phoenix Iron Co. (rerolling) $41, (forging) $47; Granite City Steel Co. $47.50.

Blooms—Phoenix Iron Co. (rerolling) $41, (forging) $47.

Sheet Bar—Empire Sheet & Tin Plate Co. $39 mill; Wheeling Steel Corp. $38 Portsmouth, Ohio.

Billets, Forging—Andrews Steel Co. $50 basing pts.; Follansbee Steel Corp. $49.50 Toronto, Ohio; Phoenix Iron Co. $47.00 mill.

Billets, Rerolling—Continental Steel Corp. may charge Acme Steel in Chicago switching area $34 plus freight from Kokomo, Ind.; Northwestern Steel & Wire Co. (Lend-Lease) $41 mill; Wheeling Steel Corp. (small) $36 Portsmouth, Ohio; (blooming mill sizes) applicable base, f.o.b. Portsmouth, Ohio; Stanley Works may sell Washburn Wire Co. under allocation at $39 Bridgeport, Conn.; Keystone Steel & Wire Co. may sell Acme Steel Co. at Chicago base, f.o.b. Peoria; Phoenix Iron Co. $41 mill; Continental Steel Corp. (1¾ x 1¾) $39.50, (2 x 2) $40.60 Kokomo, Ind. (these prices include $1 size extra); Keystone Steel & Wire Co. $36.40 Peoria; Connors Steel Co. $50.69 Birmingham; Ford Motor Co. $34 Dearborn, Mich.

Structural Shapes—Phoenix Iron Co. $2.35 basing pts., (export) $2.50 Phoenixville; Knoxville Iron Co. $2.30 basing pts.; Sheffield Steel Corp. $2.55 St. Louis.

Bar Size Shapes—(Angles) W. Ames & Co., 10 tons or over, $3.10 mill.

Rails—Sweet Steel Co. (rail steel) $50 mill; West Virginia Rail Co. (lightweight) on allocation based Huntington, W. Va.; Colorado Fuel & Iron Corp. $45 Pueblo, Colo.

Hot Rolled Plate—Granite City Steel Co. $2.65 mill; Knoxville Iron Co. $2.25 basing pts.; Kaiser Co. $3.20 Pacific Ports.

Merchant Bars—Sheffield Steel Corp. $2.75 St. Louis; W. Ames & Co., 10 tons and over, $2.85 mill; Eckels-Nye Steel Corp., $2.50 basing pts. (rail steel) $2.40; Phoenix Iron Co. $2.40 basing pts.; Sweet Steel Co. (rail steel) $2.35 mill; Joslyn Mfg. & Supply Co. $2.35 Chicago; Central Iron & Steel Co. $2.20 basing pts.; Granite City Steel Co. $2.35 Granite City; Calumet Steel Div., Borg Warner Corp. (8 in. mill bars) $2.35 Chicago; Knoxville Iron Co. $2.30 basing pts. Laclede Steel Co., sales to LaSalle Steel granted Chicago base, f.o.b. Madison, Ill.

Reinforcing Bars—W. Ames & Co., 10 tons and over, $2.85 mill; Sweet Steel Co. (rail steel) $2.35 mill; Columbia Steel Co. $2.50 Pacific Ports.

Cold Finished Bars—Keystone Drawn Steel Co. on allocation, Pittsburgh c.f. base plus c/l freight on hot rolled bars Pittsburgh to Spring City, Pa.; New England Drawn Steel Co. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to Massfield, Mass., f.o.b. Massfield.; Empire Finished Steel Corp. on allocation outside New England, Buffalo c.f. base plus c/l freight Buffalo to plants f.o.b. plant; Compressed Steel Shafting Co. on allocation outside New England, Buffalo base plus c/l freight Buffalo to Readville, Mass. f.o.b. Readville; Medart Co. in certain areas, Chicago c.f. base plus c/l freight Chicago to St. Louis, f.o.b. St. Louis.

Alloy Bars—Texas Steel Co. for delivery in U. S. except Texas and Oklahoma may use Chicago base, f.o.b. Fort Worth, Tex.; Connors Steel Co. when shipped outside Alabama, Mississippi, Louisiana, Georgia, Florida, Tennessee, Pittsburgh base, f.o.b. Birmingham.

Hot Rolled Strip—Joslyn Mfg. & Supply Co. $2.30 Chicago; Knoxville Iron Co. $2.25 basing pts.

Hot Rolled Sheets—Andrews Steel Co., Middletown base granted on shipments to Detroit or area; Parkersburg Iron & Steel Co., $2.25 Parkersburg.

Galvanized Sheets—Andrews Steel Co., $3.75 basing pts.; Parkersburg Iron & Steel Co. $3.85 Parkersburg; Apollo Steel Co. $3.75 basing pts.; Continental Steel Co., Middletown base granted on Kokomo, Ind., product; Superior Sheet Steel Co. granted Pittsburgh base except for Lend-Lease.

Pipe and Tubing—South Chester Tube Co. when priced at Pittsburgh, freight to Gulf Coast and Pacific Ports may be charged from Chester, Pa., also to points lying west of Harrisburg, Pa.

WAREHOUSE PRICES

Delivered metropolitan areas per 100 lb. These are zoned warehouse prices in conformance with latest zoning amendments to OPA Price Schedule 49.

*Recommended for large sections only. Note: The extras shown are in addition to a base price of 2.70c. per 100 lb., on finished products and $54 per gross ton on semi-finished steel major basing points and are in cents per 100 lb. and dollars per gross ton in semi-finished. When acid open-hearth is specified and acceptable add to basic open hearth alloy differential 0.25c. per lb. for bars and bar strip, $5.00 per gross ton for billets, blooms and slabs. The ranges shown above are restricted to sizes 100 sq. in. or less or equivalent cross sectional area 18 in. wide or under with a max. individual piece weight of 7000 lb.

BASE QUANTITIES

Standard unless otherwise keyed on prices.

HOT ROLLED: Sheets, strip, plates, shapes and bars, 400 to 1999 lb.

COLD ROLLED: Sheets, 400 to 1999 lb.; strip, extras on all quantities; bars, 1500 to 39,999 lb.; NE alloy bars, 1000 to 39,999 lb.

EXCEPTIONS: (1) 150 to 499 lb. (2) 150 to 1499 lb. (3) 400 to 1499 lb. (4) 450 to 1499 lb. (5) 500 to 1499 lb. (6) 0 to 1999 lb. (7) 400 to 1999 lb. (8) 1000 to 1999 lb. (9) 450 to 3749 lb. CAST IRON WATER PIPE

Per Net Ton

6-in. and larger, del'd Chicago.... $54.80
6-in. and larger, del'd New York... 52.20
6-in. and larger, Birmingham 46.00
6-in. and larger f.o.b. cars, San Francisco or Los Angeles 69.40
6-in. and larger f.o.b. cars, Seattle. 71.20

Class "A" and gas pipe, $3 extra; 4-in. pipe is $3 a ton above 6-in. Prices shown are for lots of less than 200 tons. For 200 tons or over, 6-in. and larger is $45 at Birmingham and $53.80 delivered Chicago, $59.40 at San Francisco and Los Angeles, and $70.20 at Seattle. Delivered prices do not reflect new 3 per cent tax on freight rates.

LAKE SUPERIOR ORES

(51.50% *Fe, Natural Content, Delivered Lower Lake Ports**)

Per Gross Ton

Old range, bessemer, 51.50 ..... $4.75
Old range, non-bessemer, 51.50..... 4.60
Mesaba, bessemer, 51.50 ..... 4.60
Mesaba, non-bessemer, 51.50 ..... 4.45
High phosphorus, 51.50 ..... 4.35

*Adjustments are made to indicate prices based on variance of Fe content of ores as analyzed on a dry basis by independent laboratories.

PRICES

SEMI-FINISHED STEEL

Billets, Blooms and Slabs

Pittsburgh, Chicago, Gary, Cleveland, Youngstown, Buffalo, Birmingham, Sparrows Point (rerolling only). Prices delivered Detroit are $2.00 higher; delivered E. Michigan, $3 higher; f.o.b. Duluth, billets only, $2.00 higher; billets f.o.b. Pacific ports are $12 higher. Delivered prices do not reflect three per cent tax on freight rates.

	Per Gross Ton
Rerolling	$34.00
Forging quality	40.00

For exceptions on semi-finished steel see the footnote on the page of finished steel prices.

Alloy Steel

Pittsburgh, Chicago, Canton, Massillon, Buffalo, or Bethlehem, per gross ton 54.00

Shell Steel

	Per Gross Ton
3 in. to 12 in.	$52.00
12 in. to 18 in.	54.00
18 in. and over	56.00

Basic open hearth shell steel, f.o.b. Pittsburgh, Chicago, Buffalo, Gary, Cleveland, Youngstown and Birmingham.

Prices delivered Detroit are $2.00 higher; E. Michigan, $3 higher.

Note: The above base prices apply on lots of 1000 tons of a size and section to which are to be added extras for chemical requirements, cutting, or quantity.

Sheet Bars

Pittsburgh, Chicago, Cleveland, Youngstown, Buffalo, Canton, Sparrows Point, Md.

	Per Gross Ton
Open hearth or bessemer	$34.00

Skelp

Pittsburgh, Chicago, Youngstown, Coatesville, Pa., Sparrows Point, Md.

	Per Lb.
Grooved, universal and sheared	1.90c.

Wire Rods

(No. 5 to 9/32 in.)

	Per Lb.
Pittsburgh, Chicago, Cleveland	2.00c.
Worcester, Mass.	2.10c.
Birmingham	2.00c.
San Francisco	2.50c.
Galveston	2.25c.

9/32 in. to 47/64 in., 0.15c. a lb. higher. Quantity extras apply.

TOOL STEEL

(F.o.b. Pittsburgh, Bethlehem, Syracuse)

	Base per lb.
High speed	67c.
Straight molybdenum	54c.
Tungsten-molybdenum	57½c.
High-carbon-chromium	43c.
Oil hardening	24c.
Special carbon	22c.
Extra carbon	18c.
Regular carbon	14c.

Warehouse prices east of Mississippi are 2c. a lb. higher; west of Mississippi 3c. higher.

CORROSION AND HEAT-RESISTING STEEL

(Per lb. base price, f.o.b. Pittsburgh)

Chromium-Nickel Alloys

	No. 304	No. 302
Forging billets	21.25c.	20.40c.
Bars	25.00c.	24.00c.

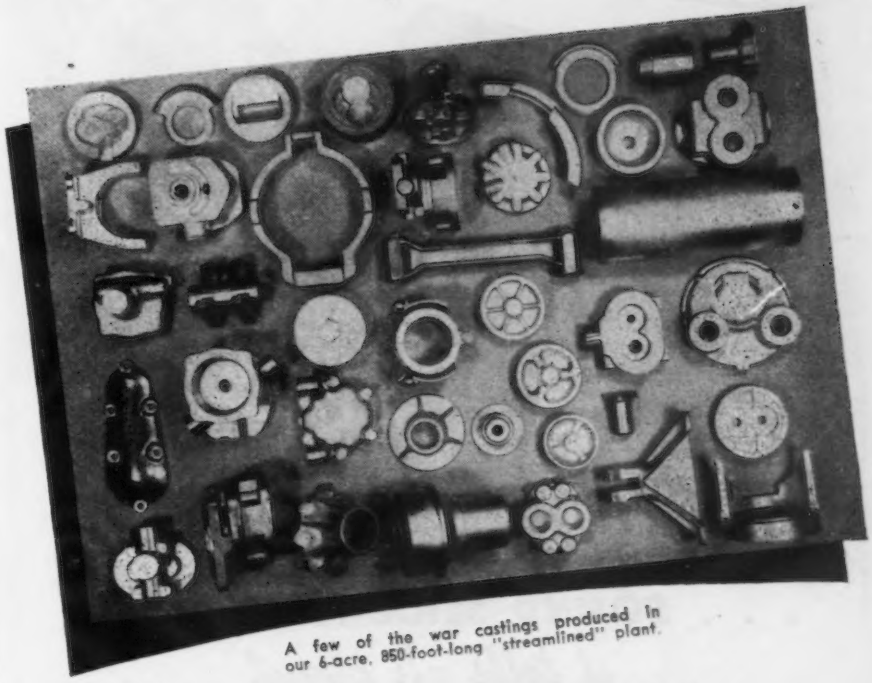
	No. 304
Plates	18.00c.*
Sheets	19.00c.

*Includes annealing and pickling.

PERMANENT MOLD
ALUMINUM CASTINGS
Prompt Delivery!



A few of the war castings produced in our 6-acre, 850-foot-long "streamlined" plant.

ALUMINUM CASTINGS

—permanent mold — of all types, sizes, and weights . . . for all requirements.

with a Complete Service • • •

PERMANENT MOLDS . . . completely engineered, designed and manufactured.

ALUMINUM ALLOYS . . . any alloy desired.

HEAT TREATED . . . to all specifications.

RIGID CONTROLS . . . X-ray inspection, controlled production, to meet the most exacting needs.

CENTRAL LOCATION . . . 15 Railroads insure prompt service to all points.

DELIVERY . . . in any quantities — and to meet all schedules.

Send us your blue-prints and specifications for immediate quotation.

. . . SOUND SLIDE FILM TODAY
it tells all about
TOOL STEEL WELDING

The Welding Equipment & Supply Company presents two sound slide films about tool steel welding that should be of vital interest to master mechanics, superintendents, tool process and tool conservation personnel, designing and method engineers, foremen and welding operators. These sound films are the only complete technical information available *anywhere* on the proper procedure and application of tool steel welding. Technical information contained in these films will help to save material, man hours, and eliminate production delays.

These sound slide films will be shown to your organization without obligation, by merely writing us on your company stationery for an appointment.

These films are also available for instruction use in schools and industrial plants at a nominal fee. Wire or write us today.

GRAY FORGE IRON: Valley or Pittsburgh furnace $23.50

(1) Pittsburgh Coke & Iron Co. (Sharpsville, Pa., furnace only) and the Struthers Iron and Steel Co., Struthers, Ohio, may charge 50c. a ton in excess of basing point prices for No. 2 foundry, basic, bessemer and malleable.

(2) Price shown is for low-phosphorous iron; high-phosphorous sells for $28.50 at the furnace.

(3) E. & G. Brooke Co. permitted to charge $1.00 per ton extra.

(4) Pittsburgh Ferromanganese Co. (Chester furnace only) may charge $2.25 a ton over maximum basing point prices.

Basing point prices are subject to switching charges; silicon differentials (not to exceed 50c. a ton for each 0.25 per cent silicon content in excess of base grade which is 1.75 per cent to 2.25 per cent); phosphorous differentials, a reduction of 38c. per ton for phosphorous content of 0.70 per cent and over; manganese differentials, a charge not to exceed 50c. per ton for each 0.50 per cent manganese content in excess of 1.00 per cent. Effective March 3, 1943, $2 per ton extra may be charged for 0.5 to 0.75 per cent nickel content and $1 per ton extra for each additional 0.25 per cent nickel.

METAL POWDERS

Prices are based on current market prices of ingots plus a fixed figure. For ton lots f.o.b. shipping point, in cents per lb.

Copper, electrolytic, 150 and 200 mesh	21⅛ to 23⅛c.
Copper, reduced, 150 and 200 mesh	20½ to 25⅛c.
Iron, commercial, 100 and 200 mesh, 96 + % Fe	13½ to 15c.
Iron, crushed, 200 mesh and finer, 90 + % Fe	4c.
Iron, hydrogen reduced, 300 mesh and finer, 98½ + % Fe	63c.
Iron, electrolytic, unannealed, coarser than 300 mesh, 99 + % Fe	30 to 33c.
Iron, electrolytic, annealed minus 100 mesh, 99 + % Fe	42c.
Iron, carbonyl, 300 mesh and finer, 98-99.8 + % Fe	90c.
Aluminum, 100 and 200 mesh	*23 to 27c.
Antimony, 100 mesh	20.6c.
Cadmium, 100 mesh	$1
Chromium, 150 mesh	$1.03
Lead, 100, 200 & 300 mesh, 11½ to 12½c.	
Manganese, 150 mesh	51c.
Nickel, 150 mesh	51½c.
Solder powder, 100 mesh, 8½c. plus metal	
Tin, 100 mesh	58¾c.
Tungsten metal powder, 98%-99%, any quantity, per lb.	$2.60
Molybdenum powder, 99%, in 200-lb. kegs, f.o.b. York, Pa., per lb.	$2.60
Under 100 lb.	$3.00

*Freight allowed east of Mississippi.

PRICES

BOLTS, NUTS, RIVETS, SET SCREWS

Bolts and Nuts
(F.o.b. Pittsburgh, Cleveland, Birmingham or Chicago)

Machine and Carriage Bolts:

	Per Cent Off List
½ in. & smaller x 6 in. & shorter	65½
9/16 & ⅝ in. x 6 in. & shorter	63½
¾ to 1 in. x 6 in. & shorter	61
1⅛ in. and larger, all length	59
All diameters over 6 in. long	59
Lag, all sizes	62
Plow bolts	65

Nuts, Cold Punched or Hot Pressed:
(Hexagon or Square)

½ in. and smaller	62
9/16 to 1 in. inclusive	59
1⅛ to 1½ in. inclusive	57
1⅝ in. and larger	56

On above bolts and nuts, excepting plow bolts, additional allowance of 10 per cent for full container quantities. There is an additional 5 per cent allowance for carload shipments.

Semi-Fin. Hexagon Nuts	U.S.S.	S.A.E.
7/16 in. and smaller	..	64
½ in. and smaller	62	..
½ in. through 1 in.	..	60
9/16 in. to 1 in.	59	..
1⅛ in. through 1½ in.	57	58
1⅝ in. and larger	56	..

In full container lots, 10 per cent additional discount.

Stove Bolts

Packages, nuts loose	71 and 10
In packages, with nuts attached	71
In bulk	80

On stove bolts freight allowed up to 65c. per 100 lb. based on Cleveland Chicago, New York on lots of 200 lb. or over.

Large Rivets
(½ in. and larger)

	Base per 100 lb.
F.o.b. Pittsburgh, Cleveland, Chicago, Birmingham	$3.75

Small Rivets
(7/16 in. and smaller)

	Per Cent Off List
F.o.b. Pittsburgh, Cleveland Chicago, Birmingham	65 and 5

Cap and Set Screws

	Per Cent Off List
Upset full fin. hexagon head cap screws, coarse or fine thread, up to and incl. 1 in. x 6 in.	64
Upset set screws, cup and oval points	71
Milled studs	46
Flat head cap screws, listed sizes	36
Fillister head cap, listed sizes	51

Freight allowed up to 65c. per 100 lb. based on Cleveland, Chicago or New York on lots of 200 lb. or over.

RAILS, TRACK SUPPLIES
(F.o.b. Mill)

Standard rails, heavier than 60 lb., No. 1 O.H., gross ton	$40.00
Angles bars, 100 lb.	2.70
California Ports	3.15
(F.o.b. Basing Points)	*Per Gross Ton*
Light rails (from billets)	$40.00
Light rails (from rail steel)	39.00
	Base per Lb.
Cut spikes	3.00c.
Screw spikes	5.15c.
Tie plates, steel	2.15c.
Tie plates, Pacific Coast	2.30c.
Track bolts	4.75c.
Track bolts, heat treated, to railroads	5.00c.
Track bolts, jobbers discount	63-5

Basing points, light rails, Pittsburgh, Chicago, Birmingham; cut spikes and tie plates—Pittsburgh, Chicago, Portsmouth, Ohio, Weirton, W. Va., St. Louis, Kansas City, Minnequa, Colo., Birmingham and Pacific Coast ports; tie plates alone—Steelton, Pa., Buffalo. Cut spikes alone—Youngstown, Lebanon, Pa., Richmond, Oregon and Washington ports, add 25c.

ROOFING TERNE PLATE
(F.o.b. Pittsburgh, 112 Sheets)

	20x14 in.	20x28 in.
8-lb. coating I.C.	$6.00	$12.00
15-lb. coating I.C.	7.00	14.00
20-lb. coating I.C.	7.50	15.00

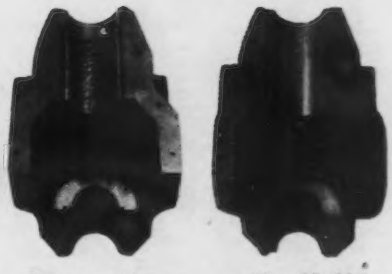
Our customers make machinable Arc Welds on CAST IRON



Before machining — After Machining
After being welded with PHILLIPS "600" Electrode this cast iron housing was machined through the fusion zone.

This book tells what procedure is best for *your* cast iron welding.

Send for your copy TODAY

PHILLIPS "600" Electrode, a non-ferrous, flux-coated rod, produces deposits that are of the color of cast iron and are *fully machinable through the line of fusion.* It can be used in all positions with A.C. or D.C. and maintains a steady and quiet arc without excessive spatter. This electrode is salvaging many valuable castings daily in hundreds of foundries and machine shops. Complete procedure information is contained in our 12-page book on "4 Ways to Salvage, Reclaim and Conserve Iron Castings by Electric Arc Welding." A copy is yours for the asking.

Business and the Doghouse

I BELIEVE it was Eric Johnson, head of the U. S. Chamber of Commerce, who recently said that business, at last, was out of the doghouse. What he meant was that the performance of industry and business in meeting and even surpassing obligations connected with war production had succeeded in changing public opinion with respect to the efficiency of private enterprise.

Mr. Johnson wisely added the caution that the door to the doghouse is still open and that whether the vacancy continues therein will depend upon how the recent occupants behave and perform in the months to come.

The question naturally arises as to who or what put them in the doghouse to begin with. It is an interesting question because the answer might point the way to keeping out of it in the future.

Ask any number of businessmen this question and you will get a variegated list of answers. One will tell you that FDR booted them into the doghouse during the first term and slammed the door shut during his second. Another will say that it was the Russian influence acting through a combination of New Dealers and fellow-travelers. Another will say it was the labor unions. Vice-President and astrologer Wallace would probably say it was written in the stars and ordained by Heaven.

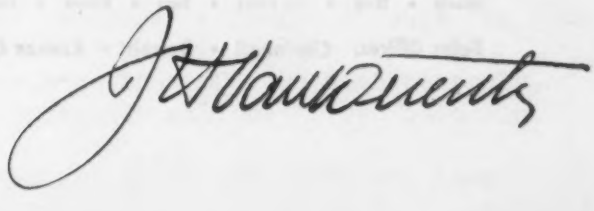
Personally I do not think that any of these were the real causes, although all of them undoubtedly helped. I believe that the people most responsible were businessmen and industrialists themselves. They went in under their own steam, or lack of it, to get out of the rain.

There are two schools of thought with respect to help in difficult situations. There is the "God help us" school and the "God helps those who help themselves" school. During the dark days of the depression, the former gained plentifully of adherents at the expense of the latter.

If children had refused to accept presents from Santa Claus, he could never have built up his enormous institution and following. Similarly, if so many businessmen and industrialists had not scurried to Washington for help and guidance in the 1930's, the chances are that bureaucracy would not have attained its present stature and that the doghouse might not have been built.

It was not the going to Washington for help that did the trick so much as the attitude of despair of many of those who went there with the "God help us" plea. Business has as much right to demand help when it needs it as labor or any other member of the American family. But, like labor, it should demand and not beg and it should go with a plan and not in a daze.

All of this is just a gentle reminder to business and industry that the doghouse is still there. Surely we will need the aid of government in solving our postwar problems, but it should be aid patterned on a plan drawn by business, industry and labor and not left to the beneficence of politicians.



Read this Shocking Truth!

Nearly 9,000,000 men and women have been killed, maimed or injured on and off the job since America went to war. Preliminary estimates for 1943 alone indicate that 4,300,000 war workers were killed or injured on or off the job—of this number 45,000 lost their lives. And, to make matters worse, non-fatal industrial accidents are increasing.

Here Is What You Can Do About It!

Study the safety organization within your own plant. Review its record. Find out whether or not it is inadequate, or has been outmoded, and cannot successfully cope with the hazards of new manufacturing methods, or greatly increased wartime employment. Satisfy yourself that it is being encouraged and equipped to perform at top efficiency. Check its program to determine whether or not employes are trained in safety for their protection when off the job as well as when on the job.

Utilize the information and opportunities for safety training offered by national agencies. Send your foremen and supervisors to the free safety engineering short courses offered at leading colleges.

If your community has a safety council, take an active interest in it. If such a council does not exist, become the leader and see that one is organized, bringing together industrialists, merchants, professional persons, civic leaders, and police, fire, city and school authorities—all the people who have the greatest interest in the accident costs of the community.

Take action today! Help conserve manpower for maximum war production—for an earlier Victory.

The IRON AGE
MARCH 2, 1944

NEWS FRONT

► Ore operators again will present OPA with a formal price increase proposal. The operators have assembled figures showing the effect of rising cost factors in narrowing the profit margin.

► The Government already has sold approximately 4,000,000 tons of excess steel, and now has nearly 2,000,000 tons to sell, according to T. S. Fitch, WPB special assistant. Saying that 15-20,000,000 tons of steel may be in the surplus category on sudden war ending, Mr. Fitch recommended that the steel industry itself set up machinery for disposal, i.e. depend on no bureaucracy.

► Germany's current railroad locomotive position is similar to that of the last war, when General Ludendorff said: "This is the time when locomotives become more important than guns".

German plants each month must turn out 300 locomotives to make good those destroyed or damaged beyond repair, and another 100 needed as replacements for those worn out. Most trains now carry several anti-aircraft guns, but armor plating the cabs is undesirable because of the heat exhaustion of crews. Each night the majority of locomotives are dispersed over the countryside around those towns within reach of Allied bombers.

The Allied air attack on Kassel wrecked Germany's foremost engine factory, the Henschel A.G.; and Soviet raids on Koenigsberg, East Prussia, have extensively damaged the great locomotive repair shops there.

More than anything else, the great losses in rolling stock was a major reason for the German General Staff decision to shorten the front in Russia.

► The armed forces now have in use over 500,000 jeeps, which seems to be the most ubiquitous of military equipment.

► The Japanese captured a great many Garand rifles in the Philippines. Later they used them against Americans in the Buna and Lae-Salamaua campaigns.

► Steel shipments of the seven principal rail lines serving the West Coast in 1940 totaled 1,642,965 tons. In 1942 the figure rose to 8,109,972 tons. The latter figure involves considerable cross-hauling, and the net movement of steel to the Far West in 1942 is estimated at 5,000,000 tons.

This is equivalent to 1700 trains of 70 cars each.

► CIO is very proud of a new contract with the Douglas Aircraft Vernon plant. It guarantees merit increases, reviews wages automatically every 16 weeks, provides an 8 per cent per hour shift differential, and provides against discrimination.

► Grass seed is being shipped to Italy by air transport. It is being planted around airports to keep down the volcanic dust which is injurious to aircraft engines.

The Allied armies in Italy must be no end confusing to the Germans and Italians. There are the Americans, English and Canadians; the French troops are primarily Goumiers, which means Berbers, who are not Moors but are white men who are remnants of the great Vandal kingdom in North Africa; the Indian troops with the British are not Indian but are Gurkhas, who are Mongolian mercenaries from the Kingdom of Nepal, which is not part of India.

► The Canadian Government has enacted a national code in wartime labor relations affecting 2,500,000 of the estimated 3,500,000 industrial employees in the Dominion. The code provides definite procedures for settlement of disputes and also provides definite penalties for both management and labor.

► Price uncertainty is holding up distribution of 1944 commercial trucks to a vehicle-hungry trade. OPA already has allowed Ford an increase of 11 per cent on the retail price of one truck model, and Reo has been permitted increases on five models.

Chevrolet has an application in for price increases straight through its line, but OPA as yet has made no decision.

► Machine tool executives now think that no more than 500,000 machine tools of the original 800,000 units built in the war emergency will be thrown onto the market as idle and excess equipment.

Arsenals, technical schools, China, the Soviet Union and other war torn nations are expected to absorb the 300,000.

A Machine Tool Builder Makes

Navy Diesel Engine Cases

. . . Faced with a rapid decline in turret lathe business, Warner & Swasey, Cleveland, took a contract for machining destroyer and submarine type diesel engine cases and developed some unique ideas in setup and tooling.

By GEORGE L. KLUTER

Works Manager,
Warner & Swasey Co., Cleveland

IT is usual to set up plant facilities to handle a given quota and type of production. Recently Warner & Swasey Co. has had to reverse the procedure and fit production to existing facilities.

In the wake of its all-time peak output of turret lathes, some 75 per cent of the total capacity of Warner & Swasey plants became available for subcontract war work. Selection of the wide range of jobs, now in progress, was made with the view to fitting them together, like parts of a jig saw puzzle, into an overall machine load that would match the capacity of existing equipment. Obviously, this was possible only in a rough way. The jobs were not readymade to fit the established setup. In replanning them, the company made some ingenious departures in operational sequence and tooling.

Among the first subcontract jobs to undergo such revision was the machining of six and eight cylinder diesel engine cases for power plants of the type used on the Navy's submarines and destroyers. The work was assigned for handling on equipment formerly devoted to production of beds of Warner & Swasey turret lathes. In contrast to the precision castings from which the turret lathe beds were machined, the diesel engine cases are a composite structure of forgings, boiler plate, and stampings, all welded together and delivered in rough form, as shown in the cutaway view, Fig. 1.

To handle existing equipment and at the same time to meet or exceed output schedules, a survey of the experience of other engine case subcontractors was made. This, when reflected against Warner & Swasey's own background of machine tool production, focussed the planning effort on simplifying the extensive drilling and boring operations required. It was concluded that the bulk of these operations could be handled more rapidly on radial drills than on the boring mills usually employed for such operations, because of the reduced time required for locating each hole in sequence.

Throughout the entire machining of these engine cases, considerable time was saved, in even the more usual processes employed, by revising setup operations to assure precision results. For example, use of two planer tables, to permit location and positioning of one engine case while a second case mounted on the other table is being planed, both speeded and improved this phase of operations. All alinement is taken from layout lines scribed at either end of each case by the welding contractor. After the required rough cuts are taken on the planer, the engine case is laid-by for a period of at least a week so that stresses released by removal of the outer surfaces of the structure have time to equalize.

Rough Planing

In all rough planing operations the case is mounted directly on the planer table as shown in Fig. 2, without use of the customary parallels in order that the fullest possible bearing surface be utilized to reduce strain on the structure. The bearing surface is shimmed and care is taken to clamp directly over such packed positions to avoid setting up stress.

During part of the finish cut, the planer is used to rough out the camshaft bearing for alinement. The lower halves of the cam bearings, welded integrally with the engine case, are 4-in. thick boiler plate in which the bearing surface is cut out with an acetylene torch.

In a subsequent milling operation, to rough and finish the camshaft groove and leave 0.003 in. for reaming stock, a large convex form cutter is used on a planer miller, shown in Fig. 3. The mating halves of the camshaft bearings are machined separately, being clamped in a turning fixture chucked in a turret lathe and bored to fit interchangeably, preparatory to reaming after assembly.

A special gage block for setting a dial indicator to the required depth of both halves of each camshaft bearing makes possible fast and accurate checking of this work.

Illustrative of the method employed to drill, countersink, ream and tap the considerable number of holes for dowel pins and attachment, lug and holddown bolts is the operation by which 32 1-in. holes are drilled in the cylinder deck. A plate jig permits full utility of the flexibility and quick positioning features of the radial drill used for the entire sequence. Four holes are provided around each cylinder bore and each is reamed to size. To save time in the final hand tapping operation, these holes are tapped to 0.002-in. undersize. The 14-pitch thread must meet specifications for a Class 5 fit, or a tolerance of —0.000 and +0.0018 in.

Cylinder Bores

To extend the advantage of radial drill operations to the roughing and finishing of cylinder bores, however,

presented an unusual problem. The cylinder sleeve bores of the eight cylinder engine cases as received consist of torch-cut openings through the 1½-in. boiler plate of the top deck and rough forgings welded integrally with the structure approximately 8½ in. below each opening.

Machining Bores

The special tool shown in Figs. 4 and 5 was designed to make a pilot cut, rough and semi-finish cut in each pair of upper and lower bores simultaneously. A second such tool gives them final finish. Since the lower of the two bores, which support the cylinder sleeve when the engine is finally assembled, requires a recess for water circulation, a third tool, with an internal expansion device activated by the drill feed, was provided.

To aline these tools for cutting the cylinder bores with a radial drill, a fixture of difficult design and structure was indicated. To simplify this phase of the tooling problem, it was decided to make the engine case itself serve as part of the necessary fixture. The tooling setup of this arrangement is shown in detail in Fig. 6.

This, of course, made it necessary to impose close tolerances on the overall planing of external surfaces of the engine cases. However, it is axiomatic that increased precision achieved in one operation simplifies its attainment in the remaining operations of a given machining sequence.

The setup for roughing and finishing the cylinder bores, with the previously mentioned special tools on a radial drill, employs a lower and upper guide plate. The lower guide plate is part of an auxiliary base for the radial drill. On it, the engine case is located against hardened and ground blocks, being brought into position by push screws. Bronze bushings are provided in the lower guide plate directly under each cylinder bore. The upper guide plate, which has inset blocks of hardened and ground steel for locating points, is supported above the cylinder deck and clamped to the camshaft structure.

In this manner, the accurately planed external surfaces of the engine case are used to reference the openings in the template with the bronze bushings in the lower plate. Together, they hold the boring bar on which the special cutting heads are mounted in alinement for cutting both upper and lower cylinder bores simultaneously, as shown in detail in Fig. 6.

The boring bar has a bushing to fit the template. Each of the two heads is equipped with a pilot cutter, to bring the bores into round ahead of the rough cutter. The latter is mounted on the opposite side of the head and slightly in advance of the pilot tool.

Additional cutters, mounted in the head, chamfer the bores and semi-finish the upper bore and the upper half of the lower bore. This leaves the lower half of the lower bore about 0.045 in. smaller in diameter, which

actually constitutes a third cylinder bore.

All eight cylinders are rough and semi-finished in this manner, it being only necessary to hoist the boring bar with its cutting heads from one opening to the next and swing the radial drill into position to continue the work. The bores are finished in similar manner, except that the cutting heads used for this operation have only three cutters in place of four, the pilot cutter being eliminated.

Finishing Cuts

On completion of the finishing cuts, the upper guide plate is removed and the upper bore is used in place of it to control alinement of the special tool used for cutting the recess between the two diameters of the lower bore. A bushing on this special tool is located in the upper bore. A plate attached to the bushing bears on the cylinder deck and supports the cutting head at the level of the desired recess in the lower bore.

A drive shaft, chucked in the radial drill, is connected to a wedge inside the cutting head. Since the head is supported by the bushing plate, the downward pressure of the drill feed causes the drive shaft to force its connected wedge between the inner end of the two cutting tools mounted in the head, pushing them out to increase the diameter of the recess as it is cut.

A bar, amounting to an extension of the lower end of the cutting head, extends into the bed plate bushing, which functions with the plate bushing in the upper bore to control alinement. The entire tool is lifted from one cylinder bore to the next by action of the arm of the radial drill.

Finishing of the crank and camshaft bores, after the mating halves of the bearings are assembled, presented an interesting problem. The detachable halves of each of these types of bearings must be completely interchangeable, making it essential that the dowel pins used for locating them be equidistant from the center line of the bearing. The detachable half of each bearing is machined separately from the half that is integral with the engine case. Each half, likewise, is drilled separately.

For the lower half of the crankshaft bearings, the dowel pin holes are 1-in. in diameter. They mate with holes in the half of the bearing welded integrally with the crankshaft. These mating holes have a ½-in. radius at the bottom. The attachment bolt holes are of similar size and spherical washers are used under the head and nut of each bolt for even distribution of stress.

To provide the double radii of 1½

o o o

and ½ in., respectively, under the nut, a flat cutter is used for roughing and a specially ground round cutter is used for finishing.

The spherical washer mates with the 1½-in. radius and the ½-in. radius provides relief around its upper edge. The cutting is accomplished as a back spotfacing operation on the integral half of the bearings, with 1/32-in. clearance held to accommodate the castellations of the nut. A 1½-in. radius is spot faced in the detachable halves.

Several further drilling operations intervene before the bearings are assembled and the engine case mounted on a horizontal boring mill for finishing the crankshaft bore. For this, gang cutters are mounted on a boring bar that is held in a fixture with three steady rests. The gang cutters rough bore, rough face and rough backface each of the nine bearings simultaneously.

For finish boring, a special floating tool was developed, shown in Fig. 7. The cutting tool shank consists of a short, square bar, about 1-in. in cross-section, at each end of which non-integral cutters ground for shearing action are mounted. These tools, Fig. 8, one for each bearing, are held in the boring bar slots by a spring and steel ball, like the device for holding the ratchet handle on a socket wrench. This permits sufficient lateral movement for each of the cutters to adjust

o o o

RIGHT

FIG. 6—This cutaway shows the operating position of the tool used in machining the cylinder bore recesses. The lower bushing receives the boring bar. The upper bushing fits the opening in the top guide plate, which would be secured to the camshaft structure. The tool is operated by a radial drill.

o o o

itself and provides accurate gang finishing of the nine crankshaft bearings. The operation is largely dependent upon a close tolerance roughing job, but since both the roughing and finishing can be acomplished in a gang operation, the work is greatly expedited.

Very close dimensions must be held from side to side of each bearing and from each bearing to the next. A special facing cutter, shown in Fig. 9, is used for this purpose, the bearings being faced one at a time to prevent accumulating error. The facing cutter head clamps on the boring bar, being a hinged and bolted collar. It is secured in position solely by its grip on the bar. Two cutting tools are mounted in this head so that adjustment of the boring bar, either to the right or left, permits finishing the faces of adjacent bearings.

Camshaft Bore Finish

The method of finishing the camshaft bore is distinctly different from the crankshaft operation. After interchangeable mating halves of the cam bearings have been assembled, the engine case is located for reaming the cam bearings on a horizontal boring mill. The first two bearings are brought down to finish size. There-

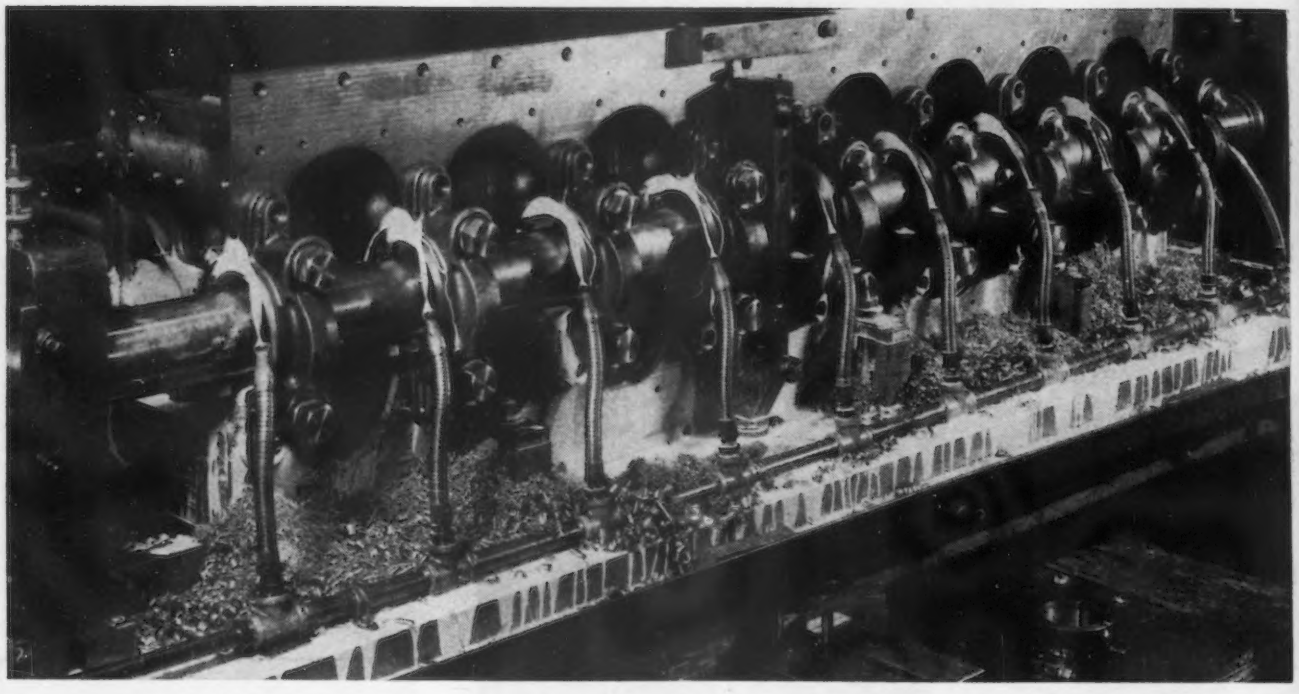

Fig. 7—For gang finishing the crankshaft bearings, special floating tools are mounted on a boring bar supported by three steadyrests.

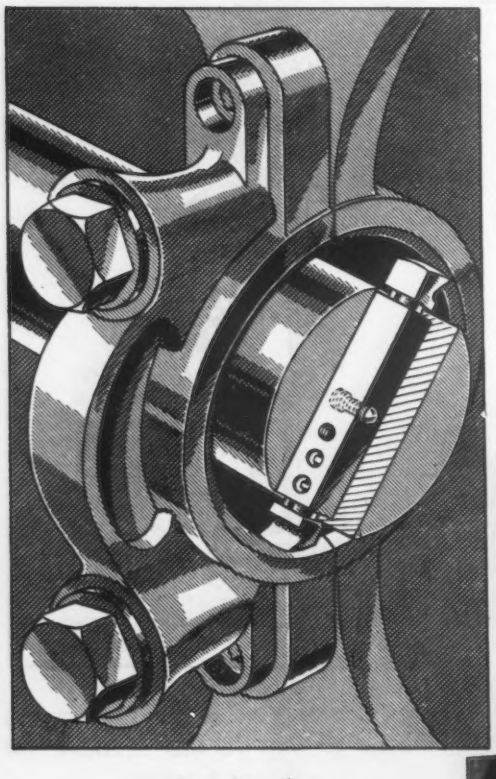

o o o

ABOVE

FIG. 8—The special floating cutter for gang finishing crankshaft bearings is shown here in detail. The cutter is secured in the boring bar slot by a steel ball, backed up with a spring that allows lateral movement for self-adjustment. Set screws aid initial adjustment of cutting edges which are specially ground for shearing action.

o o o

after, these two serve as bushings to pilot the line reamer through the next bearing.

The reaming head is mounted on a bar of the same diameter as the finished camshaft bore. Hence, as each bearing is finished in sequence, it acts as a pilot bushing for reaming the next bearing in line. The reamer is specially ground to push the chips ahead of it and the boring bar is extended with spacing sections at appropriate intervals. A test bar is passed through the completed bore to check results.

With the exception of these two operations on the crankshaft and cam bearings, and the further one of boring the large holes in each end of the

o o o

engine cases, the radial drills are consistently employed throughout the work sequence. Some deviation from standard was necessary to carry out this advantage. As an instance, the 31 holes in each end of the engine case are drilled on a 3-ft. radial drill which had to be equipped with a 4-ft. spacer to extend the column sufficiently to accommodate the 81-in. length of the engine case. A platform raises the operator to sufficient height for advantageous use of this extension, as shown in Fig. 10.

In standard operations, an additional number of holes are provided throughout the case, including those which are drilled and tapped in the welded bracket of the handhole covers at the rear.

This drilling operation, and the one in which attachment holes for the camshaft bearings, including those for dowel pins, are drilled, precedes finishing of the bearings. Holes for attachment bolts in the camshaft are both drilled and tapped on a radial drill to close tolerances, with final hand tapping operation holding the threads to Class 5 specifications. The entire case is then burr filed and hand washed.

Inspection amounts to the checking of results for each operation in sequence and the rechecking of overall dimensions. The welded assembly of these engine cases was planned to provide a high strength-weight ratio. The crankshaft bearings, for instance, comprise a forged assembly of interesting contour. They are designed to distribute the main strain of the explosion pressure throughout the engine case structure itself, which mainly consists of boiler plate.

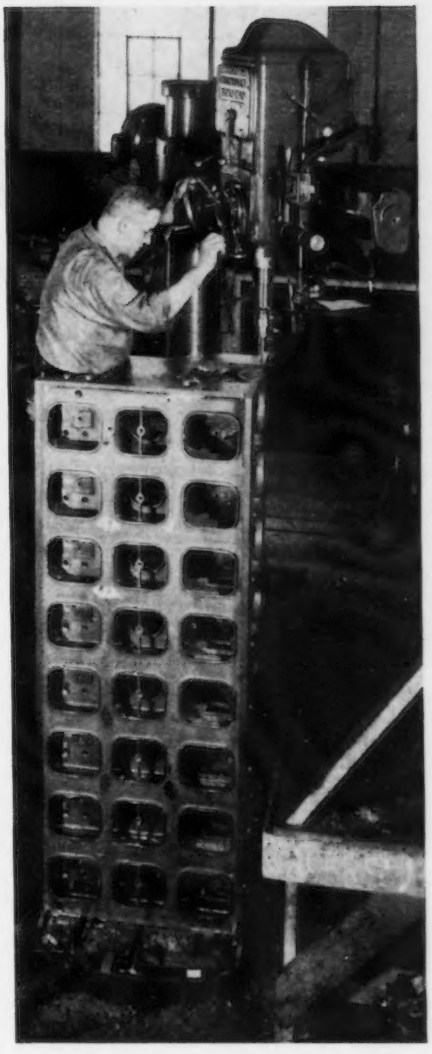

FIG. 10—A 4-ft. spacer extends the column of this radial drill sufficiently to permit its use in boring the ends of this 8-cylinder diesel engine case. The operator stands on a platform.

To facilitate this, a 34-page booklet of instructions is supplied. A copy of it accompanies each engine case throughout the entire sequence. Page by page, the booklet carries diagrammatic descriptions of each operation, graphically describing the procedure for locating the engine case, detailing both the special and standard tools to be used and summarizing results to be accomplished, in terms of the methods employed and tolerances required.

Each operation, on completion, is checked and approved by an inspector, who affixes his signature to the page on which that particular operation is described.

This special booklet, which governs all machining and finishing operations on the engine cases, was prepared with exacting consideration for their unusual design which provides a strength-weight advantage to the Navy's fighting craft. The ingenious innovations and departures in procedures, which grew out of the need to fit this job to existing Warner & Swasey facilities, have imposed more exacting demands on machine tools, with consequent saving in time and improvement in quality.

Final pages of the special booklet provide for checking of dimensions and quality of workmanship on each engine case, as a guarantee that the same precision results accompany the output of this subcontract job as those which were characteristic of the turret lathes they replaced in Warner & Swasey production.

Drop Hammer Dies Made from Cerrobend

DROP hammer dies for protype and sample parts are being made from Cerrobend metal cast from plaster patterns in the Detroit and Los Angeles plants of the Castoloy Corp. The procedure used embraces the following steps: The construction of a master model or template of plaster production of a plaster pattern of this master model by casting; the casting of dies, from the plaster pattern. This process not only produces a die for the stamping of the parts, but also provides a means of casting checking fixtures for other subsequent operations on the part.

The dies are cast directly from full-size plaster patterns of the part, in a large tank containing circulating, cooling liquid. The cooling of a die is accomplished in approximately 45 min. The metal used, a low melting point alloy supplied by the Cerro de Pasco Copper Corp., can be pumped through a long rubber hose to any mold that is ready for pouring. As Cerrobend does not shrink upon cooling, the die is an exact duplicate of the master model. Anchor lugs and cores for holding the die in the drop hammer are mounted and cast in place during the pouring. Fitting of templates and all grinding, filing, chipping and polishing operations are unnecessary. Allowance for thickness of the sheet metal is made by means of a special spraying technique. Aluminum, steel and plastic parts can be made in quantities of from one to 50 or more, depending on the type of material, thickness and accuracy required.

Efficient Sintering

By M. V. COVER
Allen Park, Mich.

PROPER control should make possible about 1000 gross tons of sinter a day on a six wind box Dwight Lloyd machine 72 in. wide, when the sinter being produced contains 60 to 61 per cent iron.

The tonnage rate of a Dwight Lloyd sintering plant for a given material depends upon the sintering rate which is the speed at which the sintering zone travels down through the bed of material to be sintered and the per cent of hot return fines. A sintering rate of 1 in. per min. has been considered satisfactory for this type of machine, but is dependent on: (1) Ignition, (2) porosity, (3) vacuum, (4) carbon, (5) moisture, (6) uniformity of mix, (7) per cent hot return fines, (8) depth of bed, (9) materials in the mix, (10) intelligent operation, (11) condition of equipment.

Ignition is undoubtedly the most important item. Unless there is good ignition produced by a flexible furnace, high efficiency in the other items will not produce maximum results. Good ignition depends upon: Type of furnace; fuel used; proper mixing of air and gas; temperature and proper application of flame; length of time flame is in contact with material; uniform and continuous band of ignition flame across the sinter bed; uniform piling of material; per cent of moisture; per cent of carbon, and a properly smoothed surface of material.

With any type of ignition furnace the air and gaseous fuel must be properly mixed, and have sufficient pressure to force the flame down onto the material. For best results individual control of the air and the gas is essential, and a wide even continuous band of flame in contact with the material clear across the sinter bed is necessary. In order to have uniform, even ignition the bed must be of even depth throughout and carefully smoothed down. The material must not be compressed to any extent.

The flame should be in contact with the material long enough and be high enough in temperature to ignite the carbon thoroughly and start it burning rapidly. Too much moisture and too little carbon are detrimental to good ignition, as is poorly mixed material. The top of a properly ignited sinter bed will be of a uniform bluish color, will not be baked but will be hard and firm, and will not be dried out.

Where the ignition fuel to be used is fuel oil, an oil gas generator can be used. About 20 gal. an hr. of fuel oil would be required. With 550 B.t.u. coke oven gas, about 3500 cu. ft. of gas an hr. is required. The ignition fuel necessary is practically independent of the depth of bed or the speed of the machine.

The coke oven gas pressure should be not less than about 15 in. H_2O per sq. in. The gas and air should have individual control valves. A covered gas line with provision for steaming out and not less than 6 or 8 in. in diameter should be provided. It would be best to have this size line come up to as near the control valve as possible.

The small orifice necessary to measure the gas accurately is not practical in a coke oven gas line. For this reason, the orifice necessary for periodical checking of the gas flow should be placed in a by-pass line. An ordinary monometer similar to a Meriam with a properly graduated scale will indicate the hourly gas flow and give a reading that is as accurate as that of any gas flow meter using an orifice. With the ignition furnace described above, the gas regulating valve is set for best results and is not changed, except when the gas pressure varies appreciably. An extra shut-off valve should be used to shut the gas off when the plant is down. The setting of the regulating valve is not changed. Since the gas is always shut off last and turned on first there is no danger of explosions when the above procedure is followed.

Porosity Second in Importance

Next to ignition, porosity is the most important item in affecting the sintering rate. It should be as high as possible and uniform across the entire sinter bed. The most important things that affect porosity in a given material are: Moisture; amount and kind of hot return fines; grate bar opening; properly and uniformly mixed material; delivery of material onto the bed; uniform depth of bed; smoothing shoes, and carbon content.

The amount of moisture necessary for best results varies with the materials being sintered, but is about 10 per cent of the total mix. A very slight change in moisture content from the optimum will affect porosity adversely. Porosity increases with the percentage of hot return fines.

The amount of grate openings should be as high as possible, the limiting factor being the amount of material that is pulled through the grate bar openings into the wind boxes. This varies with the fineness of the material being sintered and inversely with the segregation of the coarse material to the bottom of the pile. Materials must be thoroughly mixed in the pug mill so that they will be uniformly distributed across the bed. If a swinging spout is used, means must be provided to insure the fluffy piling of the material onto the bed. It is also necessary to have the coarser materials segregate and pile uniformly across the pallets and at the bottom of the pile. Having the bed the same depth across the pallets is very important, because the porosity must be uniform to obtain even results. The smoothing shoes should not be so heavy as to compress the material to any appreciable extent, but should leave it light and fluffy.

The amount of carbon necessary for greatest porosity like moisture, also varies with the material being sintered, but for best results is around 3.50 to 3.75 per cent dry basis. Any variation of this amount in either direction begins to affect the porosity of the material adversely.

Proper vacuum is also of very high importance in securing the best sintering rate. The vacuum should be adjusted to the depth of bed and to the materials being sintered. Best results would be obtained with a fan that would give a variable vacuum. With a constant vacuum fan the butterfly valve in the wind line must be kept partly closed unless the bed depth is arranged to suit the maximum

with a Dwight Lloyd Unit

. . . How to increase the amount of sinter made in a Dwight Lloyd machine by the use of proper materials and efficient design is herein described in detail. Also fully discussed are the other critical factors influencing output.

vacuum. This depth must then be varied with any pronounced changes in the material mix. Too much vacuum for a given bed depth lowers the sintering rate and causes excessive wear on the fan. It also fills the wind box with unsintered material. Nine thousand cu. ft. of air a min. per wind box seems to be about the right amount of air. The maximum vacuum of 24 in. or 25 in. commonly used is very probably not high enough to obtain a maximum sintering rate and the bed depth necessary for highest production.

A bed 13½ in. deep has been found to give very good results when running about one part dry flue dust to three parts clayey ore. With about equal dry dust and ore a bed not over 12 in. is desirable. When about 6 per cent open hearth dust is used in the total mix the 12 in. bed is too deep. With a variable vacuum the vacuum could be raised or lowered to suit conditions. Changing the opening of the butterfly valve in the wind line is not a satisfactory method of controlling the vacuum.

A variable speed coupling between the motor and the fan would be ideal for vacuum control. A coupling of this type would also be of very great advantage in starting the fan. The fan motor may take five or six times as much current for starting as it requires while running. The benefits that would be derived from gradual speed increases in starting the fan are quite obvious.

In maintaining the full benefits of the vacuum available, one of the main sources of vacuum loss can be avoided by using wear plates on the hubs of the pallets. The ordinary method of taking care of these hubs is to take the pallets out of service and build up the hubs by electric welding. When this welding is delayed too long the sealing edges of the pallets will be battered back and considerable vacuum is lost due to air pulled through these spaces. A method that works out much better than welding is to burn the hub to a radius ½ in. less than the original radius and then weld 50 to 60 point carbon wear plates on the hubs. Plates of this kind after 26 months of service show little wear. The distance between pallets at the discharge end of the machine does not increase and vacuum is not lost as a result of battered surfaces. Some of the original hubs may have as much as ½ in. worn off them in about three or four months.

Pallets should originally be made with wear plates on the hubs. The wear plates could be held on with countersunk head machine bolts. New plates could then be installed without either removing the pallet or stopping the sintering machine. Usually one or two of the hubs wear much more rapidly than the others. With wear plates only the individual plate would be removed. The average life of the plates would be more than a year, instead of a few months, and the sealing surfaces would not be battered back.

By using two spreaders with a sling at each end and two trolleys, pallets can be changed with only a 3 to 5 min. delay of the sintering machine.

When coke breeze is used for the sintering fuel it should be screened at least to ⅛ in. The finer the better. Coarse breeze is segregated down onto the grate bars and causes stickers and scabs. Considerably less breeze is required if it is fine. Too little carbon makes soft sinter. Too much carbon makes sinter that is very brittle, unless the percentage of carbon is very high. When carbon content is very high the sinter is fused into a hard mass with very little porosity, and a uniform bed of sinter is probably impossible to obtain. Such sinter is not desirable for blast furnace use.

When the sinter material is dry it has practically no porosity and it is impossible to ignite it properly. The porosity increases rapidly up to about 10 per cent moisture content, above this amount porosity decreases rapidly. With 14 per cent moisture, for example, the material is very hard to ignite and great difficulty is experienced in handling it because of its "muddy" condition. When flue dust having 10 per cent or more carbon is being sintered, more than 10 per cent moisture is needed. Most of this additional moisture should be added after ignition rather than before. A shallow bed is necessary for best results. High moisture increases the ignition loss and increases the fuel cost. If the "mix" is too dry it causes considerable trouble due to pulling through the grates.

Material Weighed Hourly

To insure the uniform mix that is so essential to a high sintering rate, hourly weights of each material should be taken. These should be held as nearly uniform as possible. A good spring scale that will weigh accurately ½ oz. to about 50 lb. plus a pan placed on the belt as needed at each feeder should be provided. From these checks the percentage of each material, its tonnage, the per cent of return fines and tonnage of sinter made can be checked fairly accurately. Nothing should be added to the feeder tables, such as rings, that interferes with the smooth even flow of the material to the belt. Only one pug mill is necessary. However, it must do a thorough job of mixing at all times. All returns should be so handled that there will be a steady flow of them back to the feed belts. Whenever there is a radical change in the mix, the weights for each material should be determined ahead of time.

Getting the best amount of returns requires some study. With a clayey ore and not too high a proportion of dry flue dust, 10 to 18 per cent for example, about 20 per cent returns have been found to give the best results. With 20 per cent returns the sintering rate may run as high as about 1.35 in. a min. With about 30 per cent returns this can be raised to about 1.45 in. a min. However, for maximum tonnage about 20 per cent returns should be used. The amount of returns made is governed by the total grizzly bar opening and by the width of the openings, as well as by

the kind of sinter that is being made.

With the usual 24-in. vacuum and materials that are not too fine, best results are obtained with a sinter bed of about 14-in. depth. Greater bed depth will give the following beneficial results: Much higher production; increased life of the grate bars; increased life of the fan blades; increased tonnage life of the pallet bearings; lower percentage of unsintered returns, and lower cost of sinter.

A good blast furnace sinter will haxe maximum porosity and will not be too coarse. It must, however, have enough structural strength to support the over burden. It must present the highest possible surface for contact with the reducing gases.

A good open hearth sinter will be as compact and as heavy as possible. It will present as little surface as possible to contact with other fusing materials. Porosity, as such, will not be detrimental to the sinter as long as it does not increase the "surface contact."

The kind and quantity of sinter made is largely dependent upon the materials available for sintering. For blast furnace purposes a more friable sinter must be made, but for open hearth purposes the sinter should be fused to as great an extent as is practical. If too much fuel is used considerable trouble will be experienced due to "scabs" and "stickers." It has been found that, with free silicon up to 5 or 6 per cent no appreciable amount of Fayolite will be formed up to the point of "sticking."

With a fine granular ore, high in iron, good open hearth sinter can be made without over-fusion. In general, for open hearth sinter fine granular material is desirable. For blast furnace sinter, coarser material that results in a more porous product is desirable.

Open hearth sinter should be handled without cooling water and should be stored in bins to cool before loading into cars. It should not be handled with a crane but can be loaded directly into cars as made, with cooling water sprayed onto the sides of the cars and not onto the sinter.

Conveyor Design

Belts for a six wind box machine should be able to handle as much as 1800 tons of total material mix in 24 hr. There have been cases in existing plants where motors and gear reducers on conveyors have been too small to perform their duties properly. Belts that have been stopped with a load on them sometimes will not start without assistance. Motors overheat and bearings, especially those on high speed shafts fail after being in service a very short time. The remedy for this is, of course, to use more power and heavier bearings.

One mistake is sometimes made in conveyor drive design. Instead of using a holdback to prevent inclined conveyors from running back when stopped while loaded, a worm gearing with a high reduction is used. The starting efficiency of this gearing must be less than 50 per cent and the running efficiency will probably be approximately 60 per cent. This means that the motor must have about 50 or 60 per cent more power to start the conveyor, and about 25 per cent greater operating power is required than would be required if helical reducing gearing and a back stop is used.

In designing handling equipment the weights of various materials may be assumed to be about as follows:

Material	*Lb. Per Cu. Ft.*
Ore	125
Flue Dust	90
Scale	175
Breeze	40
Mix	100
Sinter	100

Material should be delivered onto rubber belts exactly on the center line. If a belt is rather long self-alining idlers should be provided. Satisfactory belt scrapers other than rotating scrapers are hard to find. If a stationary scraper is used the arm holding the rubber should be rather short, but extra wide and thick and the rubber should be applied at an angle of about 45 deg. to the belt instead of at 90 deg. The short arm will prevent vibration and the scraper set at 45 deg. will peel the material off the belt instead of scraping it off. Junction boxes should have deflection plates or other means provided to insure delivery of the material to the center of the succeeding belt. These boxes should have vertical sides so as to avoid sticking of material and should have loose liners where wear occurs to facilitate replacement.

When feeders have been down for some time they are hard to start. In some cases the motor is not powerful enough. In others the clutches slip. The reducing gearing under the table in some cases consists of a worm and gear that has a reduction ratio as high as 60:1. The starting efficiency of these drives is likely to be less than 50 per cent. This means that 25 per cent or more of the motive power is lost in friction. A larger motor must be used to overcome this. Considerably more operating power is necessary for this layout than would be necessary for a design having a worm gearing of not over 20:1 reduction. With the higher ratio there is excessive wear on the worm and gear, and due to over-heating the bearings do not stand up nearly as well as they should.

Rubber belts will carry material up a slope of about 20 deg. The belts carrying the discharge from the shaker screen should have a slope of not over 10 or 15 deg. On greater slopes than these the coarse material will roll back. Belt conveyors are far more satisfactory than bucket elevators. Feeder belt speed of approximately 100 ft. per min, is quite satisfactory. With this speed a belt 24 in. wide will take care of up to 1600 tons of material in 24 hr. The belt that carries the hot fines should not be run much faster than the other feeder belts, so that sufficient protection from the hot fines will be provided for the belt by the other materials. The storage belts should have a higher speed so as to deliver most of the material to the storage bins on the day turn. However, for this purpose more storage capacity than is usually provided is needed. More receiving bins are also necessary.

The angle of the conical section of the feeder bins with the cylindrical section should be less than is sometimes used. This will cut the apparent capacity of the bin somewhat. The real capacity of the bins, however, will be increased. With the larger angle the material hangs on the conical sides of the bin and only a core about the diameter of the feeder table feeds down through. This cuts the real capacity of the bin to probably less than half of the rated capacity, especially for clayey ores and flue dust.

The leg from the hopper under the front end of the sinter machine should come straight down to the belt. A rubber skirt made from belting is placed on the bottom end of the leg and pressed down onto the belt. This arrangement keeps dust out of the feeder room and provides a steady feed for these returns.

Feeders, conveyors, pug mill and swinging spout should be connected in sequence but the sinter machine should not be in sequence. When the material feed falls off for any reason the sinter machine can be stopped until the shortage is made up. This prevents uneven piling of material.

The shaker screen should be placed in line with the belt that brings the material up to it and not at right angles to this belt. When the screen is at right angles to this belt the material sticks to the junction box chute and this causes the material to flow

onto the shaker screen at one side instead of evenly across the screen. This is very hard on the screens, slows the screening process, and causes a considerable amount of fine material to go out with the coarse material. An adjustable baffle in the junction box will partly overcome this difficulty, but much better results would be obtained by having the screen in line with the conveyor. A baffle plate suspended on cables or chains in the chute just ahead of the shaker screen will prevent coarse pieces of ore, etc., from flying off, and will protect the screen from much damage. The screens should be of the quick change type and have rectangular rather than square mesh with the long side of the rectangle in the direction of material flow. If this is not the case wet materials will pile on the screen and cause serious trouble.

Rectangular Pug Mill

Pug mills of various designs are used. One type that gives satisfactory service is a rectangular mill with square shafts and paddle assemblies. Wear plates protect the paddles and need to be changed about every fourth week. About every twelfth week the compelte shaft assemblies with coupling seals and bearings should be changed. This takes about the same time, 3 to 4 hr., that it takes to change the wear plates. Proper inspection of all these parts is nearly impossible without removing them. One should make sure that the couplings are a driving fit on the shafts and that the keys are a good fit and ample in size. Much damage can be done in a very short time when couplings become loose.

Means should be provided to lift the shafts out of the mill. The plate on top of the mill should be loose and the junction box should be split at an angle with no more than four bolts in the joints. This will be found very advantageous when changing the wear plates.

Rings around the feeder tables extending 1½ in. or so above the table level are sometimes used since it is believed the material will pack on the table inside the rings and thus prevent wear on the table tops.

It has been found, however, that when the material is at all coarse it will not pack. On receiving bin feeders where the material is quite coarse, the material catches under the bin skirt rings and wears the table top much faster than would be the case if these table rings were not used. With fine material the bin skirt rings must be kept down to close to the table to keep the material from feeding out under them instead of out of the gate. The most serious fault of the table rings, however, is due to the damming back of the material. This causes uneven feeding of the material which is quite detrimental to the sintering operation. With fine wet material the feed may be dammed back so much that the material will not feed at all without manual assistance.

Even if the material does pack more or less hard inside the table ring, the cleavage between the packed material and the material being fed is much greater than the cleavage of the material to the smooth table top. This means that more power must be used to turn the table. It is best to use wear plates of 50 to 60 point carbon steel on the table tops. These rings of about 1 in. thick last about one year or more, flue dust or scale.

Washer Dust

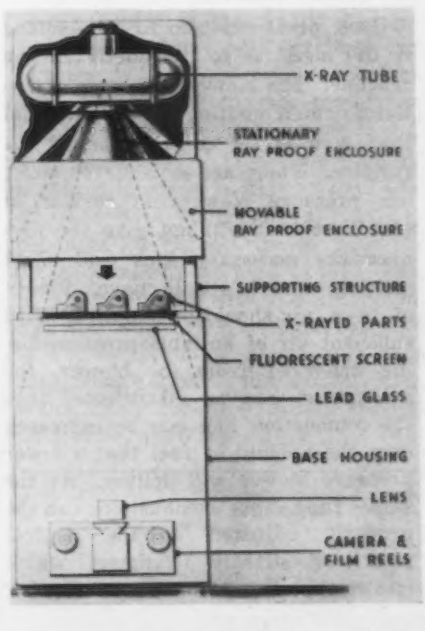
Proper handling of wet dust requires considerable engineering supervision of the design of the sludge and the filter cake handling machinery. Ample suction lines to the sludge pumps must be provided. Proper choice of a filter must be made. If a drum type filter is used then the removal of the cake from the cloth requires considerable engineering thought. Junction boxes for belts must be carefully designed. Scrapers that are entirely satisfactory for other materials will not work at all satisfactorily on filter cake. The plough that prepares the other material, including the filter cake to receive the hot fines, should be specially designed or the belt going to the pug mill will be burned up. Furthermore, a swinging spout, that will handle other materials satisfactorily will not handle high percentages of wet dust at all.

Proper drainage for the settling basins and the filter must be provided. If this is not done, plenty of trouble will be experienced.

If wet dust equipment is well engineered all the way through, then adding wet dust to sinter mix will increase the amount of sinter that can be produced, possibly by as much as 10 per cent. Up to 25 per cent of the total mix may be wet dust, and up to 40 per cent or more may consist of wet and dry dust.

X-Ray Negatives Made on Miniature Film

USE of a high speed camera to make 2-in. film negatives of any image cast upon a fluorescent screen 1 ft. square enables X-ray inspections to be made for 5c. a "shot" instead of $1.50 for 14 x 17 in full size X-ray negatives. About 300 exposures can be made on a single 50-ft. roll of film. In order to adopt the unit to production lines without endangering personnel, the machine, which was developed by Westinghouse, is designed so that no special lead lined surroundings are needed. As the diagramatic sketch shows, the tube itself is housed in a ray proof enclosure and a lead sheathed shield is dropped down over the work after it has been laid on the fluorescent screen. The camera is mounted in the base. Industrial radiograph equipment of this type, although limited to certain varieties and sizes of product, should extend the application of X-ray inspection methods to other than critically important work to which it has been largely limited because of cost of apparatus and film.



Better Copper

By H. E. McGOWAN
H. E. McGowan Co., Los Angeles

WITH the rapid development of copper alloys like the tin bronzes, nickel silver, manganese bronzes, aluminum bronzes, silicon bronzes, manganese-aluminum bronzes, and beryllium bronzes in very recent times, the foundryman will find, by some study and inquiry, that he can offer castings from these recent developments for industrial use that were not in existence a few years ago. They require some additional understanding and care in handling beyond that for ordinary red brasses, but they are here to stay and the more that is known of them, the more successful the foundry business will be.

The first important consideration is the melting practice in the foundry. It is essential that gates and ingots are melted down as rapidly as possible under proper conditions of combustion. This sounds simple enough, but there are many foundrymen who do not appreciate how important this is. Furnaces should be so constructed that the linings will radiate the highest possible amount of heat in the shortest length of time. For crucible style furnaces, silicon carbide shapes are an excellent recommendation as a material well suited to this type of furnace lining. These shapes should be backed up with one or two layers of insulation so that the heat created in the lining will remain inside the furnace, instead of being lost through the furnace shell. The more B.t.u. that can be kept inside the furnace, the faster the melting time will be with a given amount of combustion. Up to date furnaces with the right blower setup and combustion controls are maintaining furnace temperatures close to 3000 deg. F. and the answer is better quality castings.

Back pressures should be avoided if the metal is to lie quietly in the crucible. The blower is just as essential to rapid melting as the material that is used for construction of the furnace. There are entirely too many low pressure blowers in service in the West that will not give the furnace the necessary kick and short melting time it should have. Plenty of 16-oz. air should be supplied. With sufficient air of suitable pressure being delivered from the blower, the amount of gas or oil injected into the combustion line can be increased over the amount of fuel that a lower pressure blower will deliver. At the same time, this combustion can be properly adjusted at the neutral point, or slightly oxidizing, which means that the foundryman is going to get all possible B.t.u.'s into his furnace by obtaining the proper proportion of clean air and fuel. Blowers should have fresh air wherever possible. The gas company in every city is willing to take a reading of the furnace combustion and recommend proper adjustments, or an experienced supplier of furnaces can help at this point.

During the breakdown period when gates or ingots are becoming cherry red, but have not yet broken down into molten condition in the crucible, the metal is very susceptible to gas absorption and this gas cannot be entirely fluxed out or eliminated as a general rule before the metal is poured into the mold and sets up in the casting, resulting in porous castings.

Low pressure blowers do not deliver enough air to take as much gas or oil as they should which results in a reducing flame, that is, there is more gas or oil in the furnace combustion than will combine properly with the amount of air delivered from the blower. Roughly, there should be 10 or 11 parts of blower air to one part of fuel, to create a neutral or slightly oxidizing flame in the furnace.

Proper Combustion Essential

With an overdose of gas or oil in the combustion, the surplus or unburned portion of fuel will be rapidly absorbed into copper base alloys during the breakdown period that the metal has to go through before it is molten in the crucible. This is a critical period and the combustion should be neutral or oxidizing, preferably oxidizing, during this period. After the entire charge has become molten in the crucible, additional oil or gas can be turned into the combustion line more safely, as molten metal does not have the tendency to pick up gases that cherry red metal has. But automatic controls are available for either gas or oil fired furnaces, and most foundrymen know this, but a surprising number of foundries have been slow in taking advantage of this development. Certainly with green help today, furnace combustions by the guess method vary more widely from heat to heat than ever before.

Of course, proper combustion space, exact burner tip diameters, height of base block, distance of crucible from top of furnace, proper lining materials, proper blower air volume and pressure and automatic combustion control to maintain desired combustion from low to high flame, all enter the picture. This has all been brought to a very high degree of perfection and is available. Results of these improvements are definitely, (1) better quality metal from the furnace, (2) shorter melting time, (3) fuel saving, and (4) increased life of crucibles and furnace linings.

In some areas there are two suppliers of electric power, one delivering 60-cycle current and the other one delivering 50-cycle current. All foundries using 50-cycle current are automatically put at a disadvantage when it comes to blower performance. Their blowers turn over about 15 per cent less c.f.m. than they would on 60-cycle, and both the cu. ft. delivered per min. and the pressure of the air delivered drop off about 15 per cent. This should be overcome by belted blowers so that the r.p.m. in such shops is stepped up to 3450—and then these blowers will do as well as those direct drive jobs in shops using 60-cycle current.

Alloy Castings

. . . Good castings of uniform quality are the result of the combination of correct furnace construction, controlled combustion, proper sand specification and shakeout time. In this talk before the Los Angeles Chapter of the American Foundrymen's Association the author discusses the necessary controls for a copper alloy foundry.

Good or bad sand conditions can be the answer to the quality of castings, when all other factors are correct.

Sand that is weak, or too fine, will cause porous castings, and to be about right, sand should be as follows: Permeability, 25; green strength, 7; grain size, 100, and clay content, 10 per cent when moisture is at about 6 per cent. Slight variations are not injurious but to avoid porosity in castings, sand should not carry much more than 6 per cent moisture. If a greater percentage of water is needed to get a lift, the clay has been burned out or the sand has been used too long and too many fines have accumulated. These fines plug the desired openings between sand grains and reduce the permeability. Then it becomes necessary to add additional water for artificial temporary strength to replace the loss of bond, or clay, and together with accumulated fines interfering with the passageway between grain particles, the increased moisture causes excessive steam in the mold. This steam cannot get away from the casting and out into the mold so it kicks back on the molten metal. The metal is at this time starting to solidify and steam is trapped in the metal—resulting in porosity in the casting. A permeability tester and a moisture tester should be used to test the sand *before* molding, thus preventing many porosity troubles. Actually, sand should be ordered to the specifications desired.

Test Bars

Proper test bar procedure involves several points that are a mystery to many foundrymen even yet. For instance, the proper test bar for the alloy in question must be selected; the pouring temperature of the test bar in this alloy must be closely followed, and then the bar must be shaken out of the sand at a definite time after casting. Any error in one or more of these steps will either distort physical properties, or will vary the results for a series of test bar castings from the same melt.

Even red brass test bars shaken out at various times from 30 min. to overnight will give strange physical results. Good practice is to leave test bars in the sand not over an hour.

A rather thorough discussion of manganese bronze control will serve as an example to demonstrate a number of controlling factors.

Besides furnace combustion, pouring temperature, correct test bar pattern, and correct shake-out time, another factor of importance enters into the melting procedure for manganese bronze castings and test bars. This is the flaring (or burning off of some zinc while the metal is in the furnace). This is quite important and so is the proper replacement of zinc in the next heat for gates and risers that have been melted once. Flaring of the metal works as a de-oxidizing action and is helpful. A recommended procedure follows:

(1) Melt in a clean crucible or in a crucible that has been used previously for manganese. That is necessary to avoid lead contamination.

(2) Melt fast and bring metal to about 1950 deg. F. and flare or flash strongly.

(3) Use coarse, dry charcoal or glass as a cover, or a good flux.

(4) Furnace combustion should be neutral if possible or slightly oxidizing.

(5) Stir thoroughly but avoid flapping the metal.

(6) Flare zinc for about 1 min. but no longer in order to retain the tensile strength.

(7) Add 1 to 1½ per cent of electrolytic zinc or Horsehead zinc for the weight of gates or risers in the heat. None should be added for the original ingots. This reestablishes the copper-zinc ratio.

(8) Skim thoroughly and pour molds with crucible as close to sprue as possible and pour evenly to avoid surges or splashes. Agitation during pouring, or molten metal flowing against sharp angles in the mold causes an oxidation within the mold that is detrimental. This alloy will oxidize easily. Inverted horn gates, strainer cores, or skim and choke gates should be used, wherever practical. Castings should be fed at bottom and a straight run of metal in the mold is desirable. Heavy risers and feeder heads must be generously used to overcome both external and internal shrinkage, which this metal has.

(9) For pouring the test bar:
(a) Skin dry the mold.

(b) Pour at the temperature for best physical properties.

(c) Shake out after about 45 min. Leaving bars in sand for a longer time makes the metal brittle. Although the tensile strength will not be altered much elongation will be lost.

(d) When the bars are machined, the machine shop should be cautioned against heavy cuts or allowing the bars to get too hot. Machining can harm the physical properties of an otherwise good bar.

(e) If the feeder or riser section of the test bar does not show a decided shrink on the top section, the bar should be discarded.

(f) One bar should be broken in a vise before machining and if any bright yellow spots are apparent the bar has not been fed properly and shrink areas are present which rapidly lower the physical properties.

To demonstrate the importance of avoiding too long a flaring time and also the need of replacing 1 to 1½ per cent of highest grade zinc for the gate sand risers used in each heat, it is known that with the aluminum, iron and manganese contents constant of 70,000 lb. manganese, there is a very wide variation in physical properties by a variation of the copper-zinc ratio. For instance:

	58 Copper 41½ Zinc	57 Copper 40½ Zinc	58 Copper 39½ Zinc
Tensile	80,000	75,000	67,000
Elongation, Per Cent	27	33	45

This proves that burning out too much zinc by prolonged flaring reduces the tensile strength sharply while elongation will go higher than needed and the best amount of tensile and elongation can be obtained at the same time by some study of the flaring time. Yield points are better if tensile strengths are kept high and elongation just above the required minimum.

Only a 2 per cent change in the copper-zinc ratio is therefore capable of affecting the tensile strength 13,000 lb. downward and at the same time the elongation is upped as much as 18 per cent. From this it can be seen that no foundry can afford to be careless when working with manganese bronzes. Even the shake-out time of the castings should be carefully timed to deliver the best combination of tensile strength and ductility.

Summary

To deliver the best possible quality of metal into the casting and the test bars, the following should be noted:

(1) Melting conditions should be the fastest possible with correct air-fuel ratio.

(2) Sands should be consistently close to proper specifications.

(3) Pouring temperatures must be consistent together with consistent shake-out times both for test bars and castings.

(4) More controls are necessary in casting into manganese bronzes, aluminum bronzes, silicon bronzes, beryllium bronzes and nickel silvers. Each alloy must be understood thoroughly if best average results are to be obtained.

Vernier Gage Blocks Read to Hundred Thousandths

TO meet the trend toward finer tolerances in machining operations and the corresponding need for smaller increments in measurement, the vernier principle has been applied to DoAll precision gage blocks, permitting gage block combinations to be made up in steps of 0.000 01 in. instead of the conventional range of "tenths" (0.0001 in.). Two gage blocks in what is otherwise a normal set have a precision taper on their mating faces, with two index marks on one and a vernier scale on the other divided into 10 parts between index marks.

When the taper faces of the two blocks are wrung together, with the taper index marks coinciding at each end, the combination forms a block with a height of 0.70000 in. By sliding the vernier scale block to the right, the height of the combination is increased one hundred thousandth for each graduation because of the taper. Sliding the block to the left, the height of the vernier gage is decreased a like amount for each graduation. The vernier gage has a total range of plus or minus 0.0001 in., thereby enabling dimensions to be made in increments of 0.00001 in. above or below any dimension which can now be made with a standard set of precision gage blocks.

Gage blocks used in combination with this vernier increase the versatility of a set of gage blocks and eliminate the cost of producing special gages where the dimensions must be held to split tenth accuracy. Practically all types of snap gages, Fig 1, can be quickly set up. A simple setup will produce height and depth gages to millionth accuracy with a fraction of the cost of a special gage. No special skill is required in setting the gage, which is wrung together in the same manner as standard gage blocks. In combination with gage blocks, a precision sine bar, Fig. 2, can be set to angles within 2 sec. of arc.

Toolmakers and inspectors can quickly measure any dimension to within hundred thousandths of an inch. Continental Machines, Inc., 1301 Washington Avenue South, Minneapolis 4, developed this DoAll vernier gage.

FIG. 1—The DoAll vernier gage blocks used in combination with standard gage blocks and gage holder quickly makes up a snap gage measuring to hundred thousandths with millionth accuracy.

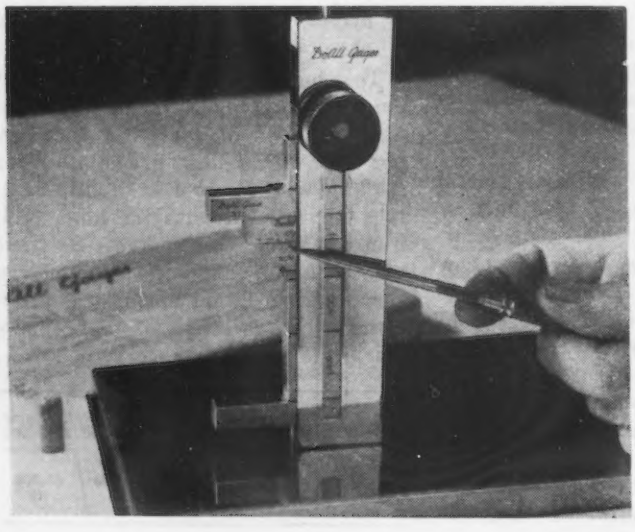


FIG. 2—The DoAll vernier gage in combination with standard gage blocks, master flat and sine bar, for measuring the accuracy of any angle to within 2 sec. of arc.

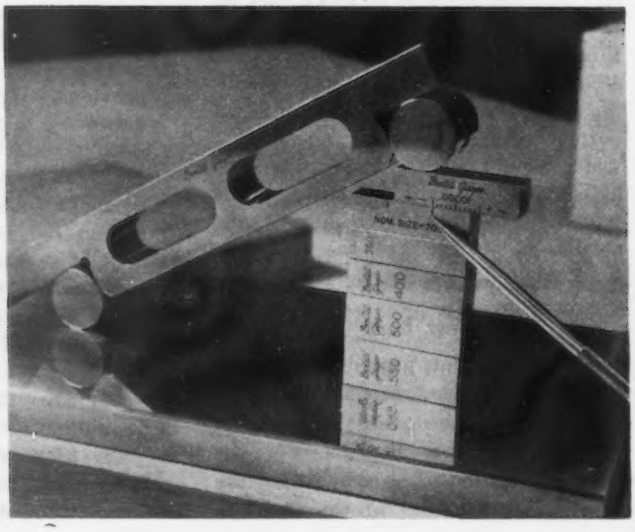

A. I. M. E. Discusses War and Postwar Problems

. . . At their third wartime annual convention, the mining and metallurgical engineers assembled to hear about new research on the powers of boron, powder metallurgy and magnesium reduction.

o o o

TOPPING last year's attendance, approximately 3000 members met in New York last week at the third wartime annual convention of the American Institute of Mining and Metallurgical Engineers to hear a four-day program, Feb. 21 to Feb. 24, of technical papers, round-table discussions and symposia.

Among the noteworthy events was the awarding of the eighth Robert W. Hunt gold medal and certificate at the Institute of Metals banquet on Wednesday evening, Feb. 23, to Clarence D. King, chairman of the operating committees, United States Steel Corp. of Delaware, for the work done and summarized in his paper, "Washing of Pittsburgh Coking Coals and Results Obtained in Blast Furnaces," presented to the 1943 Cleveland conference of the Blast Furnace and Raw Materials Committee. Mr. King reported that by a relatively simple washing treatment applied to Pittsburgh coking coal, pig iron production could be increased 8 per cent, net furnace coke consumption decreased 8 per cent and flux consumption decreased 15 per cent. In addition, improvement was noted in the regularity of the analysis of the pig iron.

To Alfred H. Geisler, research metallurgist at the Aluminum Research Laboratories, Charles S. Barrett and Robert F. Mehl, both of the Carnegie Technological Institute, went the 11th Institute of Metals Division award for their paper "Aging in the Solid Solution of Silver in Aluminum."

The 18th recipient of the J. E. Johnson, Jr., Award was Leonard A. Tofft, general foreman of the new war-plant blast furnaces of the Inland Steel Co. for "Use of Inwall Temperatures in Determining Improper Gas Flow."

James T. MacKenzie, chief metallurgist of the American Cast Iron Pipe Co., Birmingham, delivered the 21st Howe Memorial lecture on "Cast Iron—Steel Plus Graphite." Mr. MacKenzie discussed the mechanical performance of cast iron and the relation of this performance to the concept of cast iron as steel plus graphite.

Chester A. Fulton, new president of the A.I.M.E., spoke at the Institute of Metals Dinner where Arthur Phillips, new division chairman, made his inaugural remarks. Inducted as chairman of the Iron and Steel Division was William A. Haven, vice-president of Arthur G. McKee & Co.

Protecting Boron Additions to Liquid Steel

A STIMULATING paper presented by R. W. Gurry of the research laboratories of the United States Steel Corp. at the Steelmaking and Deoxidation session on "The Relative Deoxidizing Power of Boron in Liquid Steel and the Elimination of Boron in the Open-Hearth Process" raised the question as to what extent any boron present in the scrap charged into the open hearth is oxidized out during melting and subsequent refining. This question is significant because the optimum concentration of boron in the finished steel, which is fairly critical, would be very difficult to attain if the boron in the charge were largely retained in the metal. Moreover, unless boron is substantially eliminated in the open-hearth process, its use on a large scale would eventually make it impossible to produce boron-free steel except by restricting the charge to virgin material.

Although there is at present virtually no satisfactory direct evidence to provide an answer to this question, there are indications from practice that boron is oxidized out in the open hearth in the production of medium or low carbon steel. It may be retained, however, if the carbon content is fairly high; that is, if the oxygen is kept fairly low.

From thermodynamic calculations it has been shown beyond doubt that boron is an effective deoxidizer for iron and should, therefore, be almost entirely removed during the open-hearth process; more specifically, the deoxidizing power of boron is greater than that of silicon, vanadium or

titanium and approaches that of zirconium or aluminum.

The relatively high affinity of boron for oxygen indicates that boron, unprotected, tends to oxidize out during teeming; hence, if "fading" is to be avoided, the boron must be protected by the addition of a more powerful deoxidizer, which means that preferably the steel should be thoroughly deoxidized before the boron is added.

If the boron is introduced as ferroboron, the steel should first be deoxidized with aluminum or some other very powerful agent; if boron is added in the form of a complex alloy containing a good deoxidizer like aluminum or calcium, the presence of these elements in relatively high concentration usually suffices to protect the boron, although the extent of this protection varies significantly with such conditions as the original oxygen content, the temperature of the liquid steel and the composition of the deoxidizing alloy.

Sintering vs. Hot-Pressing Compacts

REPORTING on "Some Properties of Sintered and Hot-Pressed Copper-Tin Powder Compacts," Claus G. Goetzel, assistant director of research, American Electro Metal Corp., Yonkers, N. Y., described the results of experiments on powder mixes corresponding to 95-5, 90-10, 85-15 and 80-20 Cu-Sn.

All sintered bronze compacts underwent only negligible changes in weight during heat treatment, with maximum weight gains of 0.29 per cent and maximum weight losses of 0.67 per cent. Volumetric changes, on the other hand, were considerable. For low tin compositions alloy powder compacts shrink less than mixed powder compacts in the low pressure range, but this is reversed for the tin-rich compositions, for which shrinkage figures above 30 per cent by volume were observed for very lightly briquetted material.

Pre-alloying of the powders promoted increased homogenization in all hot-pressed samples, but it was much less effective in sintered specimens, with virtually no effects on the 95-5 and 90-10 compositions. Other features of the microstructure are decreased porosity with rising pressures and grain growth and normalization of the structure during sintering. For hot-pressed material, greatly increased densification is coupled with only partial recrystallization and substantial retention of a structure of closely agglomerated powder particles.

Specimens hot-pressed at 572 deg. F. show lowest physical properties, with the sole exception of the hardness of cylinders pressed at 50 tons per sq. in. Specimens hot-pressed at 932 deg. F. reach theoretical densities, high hardness and compressive properties comparable with normal alloys of similar composition. Sintered alloys have intermediate density and compressive-strength values and, of course, lowest values for hardness. The kind of initial material has the following effects: Density of the sintered compacts is improved by pre-alloying and the opposite is found in most instances for hot-pressed compacts; specimens of the tin-rich compositions pressed at 932 deg. F. at high pressures are the only exception. Hardness values show a similar trend, except that low-tin pre-alloyed powders form harder compacts when hot-pressed. The use of alloy powders leads to improved compressive properties in all compositions made by both methods.

When comparing the cold-press and hot-press methods, the superiority in density and hardness of hot-molded materials is most striking. Using the relatively low temperature of 932 deg. F., completely dense alloys with a hardness comparing favorably with wrought metal are obtainable. Die life at such temperature is still reasonably long for high hot strength alloy steels. At the same time high strength and ductility are achieved if proper care is taken to make alloying effective. Possibly all these properties can still be improved if higher molding temperatures are employed.

The hot-press method offers definite possibilities for the production of certain solid bronze parts and bearings, where closest tolerances, high density and good mechanical properties or corrosion resistance are required. In the manufacture of porous parts, like self-lubricating bronze bearings, the conventional cold-press and sintering process has its established merits. However, the experimental results show that a porous bronze of the 90-10 composition with about 25 per cent porosity and a hardness of about 50 Brinell needs approximately 20 tons per sq. in. briquetting pressure against 2 tons per sq. in. or less when hot-pressed at or above 932 deg. F. At the same time the entire sintering and final sizing operation can be eliminated.

o o o

The Pidgeon Process for Mg Production

DESPITE the success in producing metallic magnesium by the electrolysis of a molten salt, there were sufficient inherent objections to justify the search for a direct reduction method. Direct thermal reduction of magnesia offers many attractive features. It widens the choice of raw materials, relaxes the rigid electrolytic requirements of raw material purity, and by obviating direct current, offers simplicity of plant equipment. With this preface, Dr. L. M. Pidgeon and W. A. Alexander went on to describe the pilot plant development of the Pidgeon process which subsequently formed the basis of operation of six commercial plants—one in Canada and five in the United States.

Because magnesium, unlike aluminum, is volatile at relatively low temperature, they explained direct reduction methods can be used where they are impossible with aluminum.

The basic reaction is $MgO + X \rightleftarrows XO + Mg$. If X is non-volatile, the reaction may be forced to the right at high temperatures by the evolution of magnesium vapor, despite the large negative value of the heat of reaction which is almost bound to follow the use of any available commercial reducing agent.

The cheapest "X" is, of course, carbon, but this notable advantage is modified by the production of a volatile oxide CO so that both Mg and CO are evolved simultaneously. Elaborate devices are required to shock cool the equilibrium mixture in order to prevent back reaction. At best a pyrophoric powder is produced requiring redistillation to provide marketable metal. The practical development of this process is due to the work of F. Hansgirg and his methods have recently been given a trial on a grand scale in the plant at Permanente, Cal.

A second class of available reducing agents they said are those which produce non-volatile oxides. When XO and X are non-volatile, magnesium is the only volatile member of the sys-

tem. It may be evolved in a simple distillation step and condensed without the formation of powder.

Two basic requirements must be fulfilled in order that such a reaction may proceed:

1. The reducing agent when heated to a reasonable temperature in the presence of MgO must result in the production of an appreciable equilibrium vapor pressure of magnesium. This magnesium must be removed continuously.

2. A supply of heat must be maintained.

In order to fulfil (1), operations must be conducted in vacuo or in a stream of H_2. Owing to its greater efficacy and relative safety, vacuum was employed in the work they described.

The choice of a suitable reducing agent formed the subject of an extensive series of small scale experiments which examined the reactions between calcined dolomite, magnesia and calcined serpentine, and such reducing agents as silicon, aluminum, calcium carbide and calcium silicide. The greatest commercial possibilities were offered by the reaction between calcined dolomite and silicon in the form of ferrosilicon.

$$2CaO + 2MgO + (XFe)Si \rightleftharpoons (CaO)_2 SiO_2 + 2\,Mg + (XFe).$$

The availability of dolomite is an outstanding advantage. The lime forms a silicate in the residue thereby preventing loss of available magnesia by a similar reaction. Ferrosilicon was the cheapest reducing agent (in dollars per equivalent) of this type available at the time this work was initiated. Aluminum and aluminum-silicon alloys are chemically more attractive, but the former is too expensive in normal times, while the latter has been unavailable in commercial quantities and has yet to be produced as cheaply as ferrosilicon on an equivalent basis.

The reactants are solids and the residue remaining after magnesium vapor is evolved is a solid. Under such conditions, the ferrosilicon and calcined dolomite must be reasonably finely ground to permit the reaction to proceed to completion. From small scale experiments carried out at the National Research Council at Ottawa it was found that small briquets would react at reasonable velocities at a temperature of 2012 deg. F.

The difficulties of developing apparatus for conducting this reaction on a commercial scale are evident from the following requirements:

(a) Heating calcined dolomite and ferrosilicon in briquetted form to a reacting temperature and maintaining a supply of heat at this temperature sufficient to overcome the endothermic reaction.

James T. MacKenzie, chief metallurgist of the American Cast Iron Pipe Co., Birmingham, was this year's Howe Memorial lecturer.

o o o

(b) Receiving a solid charge of briquets and discharging a residue of similar shape and form. The reaction zone must be in vacuo during the evolution of magnesium vapor.

(c) Removing magnesium vapor continuously and completely under non-oxidizing conditions.

(d) Condensing the magnesium vapor in a form capable of safe handling and ready conversion to ingots or other marketable form. The purity of the latter must be as high or higher than that of ingots already available by established commercial production methods.

Because of the problems presented, it was considered that a continuous apparatus was beyond the available technique and pilot plant research facilities.

That the reaction system must be loaded, unloaded, and evacuated, suggested a retort or autoclave, with the minimum number of openings heated at the closed end, with the open end protruding from the hot zone, water cooled and fitted with a vacuum tight closure. Such an apparatus may be loaded and unloaded as a batch operation, and may readily be evacuated. Since the magnesium vapor is condensed in the cool part of the apparatus soon after formation, all handling of this very reactive gas is obviated.

Early experiments with horizontal retorts were considered sufficiently promising to proceed with the construction of a large pilot plant. For the preliminary pilot plant, 8-in. heat resisting steel retorts with a wall thickness of ⅞ in. were chosen and such retorts have given nine months' life without collapse in full scale plant operation, while 90 per cent of the retorts were still in operation at 359 days. Later a 10 in. retort with a 1 in. wall was designed.

The calcined dolomite and ferrosilicon in briquetted form reacted in these retorts in vacuo at temperatures of 2100 deg. to 2120 deg. F., giving 70 to 80 per cent reaction of the silicon.

The metallic magnesium is deposited in a simple tubular condenser inserted in the cold end of the retort. A massive deposit of crystals is secured by correct condenser design and temperature. Alkali metals must be separated effectively from the magnesium since the admission of air will cause the hot alkali metals to ignite. Fire was generally transmitted to the magnesium crown resulting in partial or total loss. The crown of magnesium is pressed from the condenser and the latter is returned to the retort. Crowns may be melted to ingots with not more than 3.5 per cent loss. The magnesium is exceedingly pure, they said, Mg content being greater than 99.9 per cent.

The dolomite should be largely $CaCO_3MgCO_3$. Since high purity stones are of widespread occurrence, there would appear to be no need for considering a dolomite with a $CaCO_3$-$MgCO_3$ content lower than 97 per cent. Alkali metals should not be present in large concentration. For the ferrosilicon, a grade of 75 per cent was found to be the most economical to employ under existing market conditions.

At operating temperatures of 2100 deg. to 2120 deg. F. in a direct gas-fired furnace, a retort with i.d. 8 in., wall thickness ⅞ in., and composition 35 Ni 15 Cr steel has a life of at least 6 months. Heat resisting steels may be cast into retorts which may be made vacuum tight. Pressures of about 0.1 mm. Hg are required to produce good deposits. However, pressures below 0.5 mm. while they do not increase yields, do improve metal deposits. Pressures as low as 0.002 mm. Hg were tried without improvement in the yield.

With the high purity dolomites employed, over a limited range calcination temperature is not a vital factor in the reactivity of the charge itself. Calcination, however, does affect briquetting and therefore the process as a whole.

Particle size of calcine and ferro-

silicon was not found to be critical provided a reasonably fine subdivision is achieved. For ferrosilicon 65 mesh and 30 per cent—30 plus 100 and 30 per cent = 200 mesh for calcine are suitable. In general, grinding should be adjusted to facilitate briquetting.

Strong, dust free briquets of density in excess of 2.0 are most desirable. From experiments with two types of piston press the following observations were made:

1. Crystalline dolomite produced calcines more readily briquettable than the microcrystalline variety.
2. A wide range of particle sizes assists briquetting.
3. Precompression assists briquetting, and is, in fact, essential to some calcines.
4. Lubricants such as graphite did not improve briquetting when added in the small amounts permissible.

Retort output and silicon efficiency with different cycle times are to a certain extent inversely proportional.

Cycle time hr.	Si Efficiency per cent	24 Hr. Output* lb.	Lb. per 24 Hr. per Sq. Ft. of Hot Retort Surface
4	65	66.0	7.8
6	77	52.2	6.2
8	80	40.7	4.8

*Assuming 8-in. retorts holding 100 lb. of charge.

The externally heated retort, if fuel fired, permits the production of magnesium by the use of approximately one-half the electrical energy of the established electrolytic process, they pointed out, and this energy is a.c. and not d.c. This is shown in the table below where it is assumed that 1 net ton of 75 per cent ferrosilicon required 8000 kw-hr.

Silicon Efficiency per cent	75 per cent Si Consumed per lb. Mg Produced	Basic Power Kw.-Hr. per Lb. Mg.
65	1.21	4.84
70	1.12	4.48
75	1.05	4.20
80	.98	3.92

When dolomite is present in excess, silicon efficiency is highest but metal output per retort may be lower. The choice of an ideal ratio depends upon many factors and is beyond the scope of the pilot plant.

One Plant's Experience:

FOLLOWING Dr. L. M. Pidgeon's discussion of the pilot plant development of the ferrosilicon process, Andrew Mayer, chief engineer of the National Lead Co., New York described in a paper entitled "Plant for Production of Magnesium by the Ferrosilicon Process" his company's experience at its Luckey, Ohio, plant.

This plant was constructed at the request of the government and operated by Magnesium Reduction Co., a wholly owned subsidiary. Plant capacity was rated at 5000 tons of magnesium annually.

From tests made under Dr. Pidgeon's guidance it was found that the dolomite should contain not less than 21 per cent MgO and not more than 2 per cent acid-insoluble material. Second, the dolomite should contain less than 0.10 per cent sodium plus potassium in order to avoid serious fires caused by spontaneous ignition when the retort is opened.

The dolomite is calcined in coal-fired shaft kilns, and the calcine and ferrosilicon are ground and mixed. The mixture is then briquetted to an average density of 2.15 grams per cc. No suitable binder for the briquets has as yet been found and production of strong briquets, which are essential for efficient operation of the process, has been a difficult problem, Mr. Ware said, involving high power consumption and excessive maintenance costs.

These briquets are charged into tubular retorts of chrome-nickel steel which are set horizontally in a furnace with the open ends projecting outside the front wall. The furnace is fired by low-pressure velocity burners made by Surface Combustion Co. which are supplied with air at 20 oz. pressure. There are three zones of temperature control, one in the middle and one at each end. The temperature of each zone is controlled by a Bristol pneumatic indicating recording controller, which regulates the gas flow to the top burners. The bottom burners are adjusted manually when the furnace is started and thereafter the gas flow to them is virtually constant under normal operation conditions. The gas flow to both top and bottom burners is reduced automatically if the furnace temperature should become excessive and is shut-off automatically if the supply of 20-oz. air should fall.

Into each retort, five paper bags of briquets (225 to 250 lb.) are charged by hand and the retort fittings are inserted. After a "burn-off" period of 10 to 30 min., to reduce the proportion of combined water, the retort is closed and the vacuum is applied. Average time under vacuum is about 9½ hr.

Magnesium is liberated according to the reaction

$$2(MgO, CaO) + Si \rightleftharpoons 2\,Mg + 2\,CaO, SiO_2$$

The temperature of the furnace is so adjusted that the temperature of the retorts is 2130 deg. F. toward the end of the retort cycle. There is a slight rise in temperature when the retorts are opened, he explained, followed by a distinct drop upon charging. For the rest of the cycle, however, it remains fairly constant.

Average pressure in the furnace is 0.05 in. water and the air-gas ratio is adjusted so that the waste gases contain about 1 per cent oxygen. Each furnace consumes about 6200 cu. ft. of gas per hr. at the beginning of the cycle and 2800 at the end.

Cooling water is recirculated through the water jackets of the retorts at an average rate of 1 gal. a min. Water temperature and rate of flow is not critical but the jackets must be kept filled.

At the end of the 9½-hr. period, vacuum is broken and the retort is opened to remove the fittings and condensed magnesium. Most of the retort residue is discharged mechanically, a small remainder being hoed out by hand.

With a mix ratio of 28 lb. silicon to 80.6 lb. magnesia, 235 lb. of briquets will yield 31.5 lb. of recovered magnesium, making the silicon efficiency 65 per cent.

The magnesium deposit, in the form of a "muff" is driven out of the removable sleeve by a pneumatic hammer provided with a steel disk that fits inside the sleeve. These magnesium muffs are transferred to the melting and alloying department where they are melted down and alloyed by the usual methods.

A few lots of unalloyed magnesium ingots have been produced at the plant, Mr. Ware said, with the following typical spectrographic analysis: Copper, <0.005 per cent; lead, <0.005; iron, 0.003; nickel <0.005; manganese, 0.001, and silicon, <0.008.

Estimated life of the retorts has been estimated at about 250 days. In general, failure has been due to scaling and to cracks caused by "blowing up" after collapse had become extensive.

Additional Developments:

CONTINUING the discussion on the Pidgeon process, W. M. Peirce, R. K. Waring and L. D. Fetterolf of the research division, technical department of the New Jersey Zinc Co., Palmerton, Pa., called attention in their paper "Some Developments in the Production of Magnesium from Dolomite by the Ferrosilicon Process" to the major advantage of this ferrosilicon process which is that the retort is not cooled down

C. S. Barrett, Robert F. Mehl and Alfred Geisler (left to right) received the Institute of Metals award for "Aging in the Solid Solution of Silver in Aluminum." Dr. Mehl is now delivering the second of a series of lectures on metallurgy at the Escola Politecnica of the University of Sao Paulo, Brazil.

between charges. Earlier investigators, they recalled, had used apparatus that necessitated cooling and reheating of the retort between charges.

Although in his original work, Pidgeon briquetted the dry mixture of calcined dolomite and ferrosilicon in a plunger press under very high pressure, plans for commercial practice called for briquetting in a roll press. After several weeks of experimentation, no satisfactory dry briquets were made in any roll press available at the start of the investigation. This led to experiments with wet briquetting. Sufficient water was added to slake the lime and to provide excess water to give a plastic mix. The excess water was then removed by drying at 230 deg. F. and the water of hydration was removed by heating the charge to 1112 to 1292 deg. F. in an externally heated muffle. Excellent briquets were produced by this procedure and after several months' work, the following process was developed:

1. A mild calcination of the dolomite to yield a calcine that would hydrate readily.

2. Hydration of the calcine with about 12 per cent excess water followed by addition of the ferrosilicon and thorough mixing. This can be done in a heavy muller, a paddle mixer or a cement mixer.

3. Densification of the mix by passage through smooth, corrugated or briquetting rolls.

4. Briquetting of the densified mix by passage through briquet rolls exerting a pressure on the mix of about 2000 pounds per square inch.

5. Removal of free water from the briquets in a drier.

6. Removal of water of hydration and preheating the briquets in an externally fired steel tube. This tube was inclined at about 45 deg. and was 8 or 10 lb. in. in internal diameter. A tube of a larger diameter was tried and found to have a lower capacity because of the difficulty in driving heat to the center of the charge with the limitation in firing temperature imposed by oxidation of the silicon. The tube was fired at a temperature of 1562 deg. F. Use of a higher temperature had an adverse effect on the recoveries obtained in the subsequent reduction, presumably because of oxidation of silicon.

7. Charging the preheated briquets into the reduction retort.

A serious drawback to this wet briquetting process in commercial operation would be the low capacity of the externally fired preheaters. Heating in an internally fired rotary kiln was found to be simpler and cheaper than preheating in indirectly fired muffles.

Some dolomites were used in which part or all of the magnesia hydrated, resulting in a decrease in the density of the preheated briquet of about 1.7 to 1.3 grams per cc. Of the various remedies tried to retard magnesia hydration, the use of 1 per cent sodium chloride or calcium chloride was found to inhibit hydration partially. Further work on this possibility is in progress.

Production of usable briquets was tried with the Komarek-Greaves press which is a high-pressure roll press designed for briquetting dry materials. Even with this press, it was a difficult matter as this press works too near the limit of its capacity in handling the power input necessary to produce a briquet of good strength. The operating load must be limited to avoid excessive maintenance and roll breakage.

A number of interrelated variables influence the quality of the briquets, and the optimum values that are universally applicable do not exist for each of these variables. Important factors affecting briquet quality are the nature of the dolomite, method of calcining, size to which the calcine is crushed, method of operating the feeder and press, and the moisture and carbon dioxide content of the briquets. If the moisture and carbon dioxide content are allowed to be above 1 per cent in the briquets as they are charged into the retorts, they disintegrate during the reduction treatment. This disintegration becomes increasingly severe as the moisture and carbon dioxide content increase.

The addition of 1 to 5 per cent fluorspar to the dolomite prior to calcination profoundly influences the nature of the calcine and makes it possible to attain a briquet density of about 2.5 grams per cc., thereby permitting a proportional increase in the weight of briquetted material which can be charged to the retort, and under normal operations, with some dolomites may lead to an increase in magnesium yield of nearly 25 per cent. The fluorspar addition also makes the calcine less susceptible

to absorption of moisture and carbon dioxide.

The disadvantages of wet briquetting are the necessity of a hydration step, a preheating setup and a lower density briquet resulting in a lower charge weight in the retort. The advantages of this method are simpler and less expensive briquetting with high press capacity, production of a much stronger briquet of any desired size, freedom from disintegration of the briquets during reduction. The consequent absence of fines in the retort charge makes it feasible to obtain more complete utilization of silicon and to use a shorter reduction cycle.

The disadvantages of dry briquetting are a difficult and expensive briquetting operation with low press capacity, a relatively weak briquet of small size and a strong tendency to form fines in the charge due to the weakness of the briquets and to their tendency to absorb moisture and carbon dioxide. The presence of fines in the charge causes less efficient utilization of silicon and lower yields of magnesium per unit weight of charge.

The outstanding advantage of dry briquetting is the higher briquet density, which permits higher charge weights and greater magnesium yield per retort.

Earlier in the investigation, it seemed that taking all factors into consideration, the wet briquetting method was preferable. In view of the recent experience with very small dry briquets and particularly the discovery that dry briquet densities in excess of 2.5 grams per cc. can be attained by use of fluorspar, the investigators are inclined under most conditions to favor dry briquetting.

Reduction tests were made in a block of four individually oil-fired retorts. The retorts were of the standard 10-in. i.d. alloy-steel type with 5 ft. of their length in the heated zone. Each retort was connected to a Stokes mechanical vacuum pump of 28 or 50 cu. ft. capacity, so that individual operation was possible.

Charging of wet-process briquets involved handling hot preheated briquets at about 1292 deg. F. and these were weighted in buckets, deposited on a trough and pushed into the retort which was connected to the vacuum line immediately after charging was completed.

The silicon efficiencies obtained were 70 to 75 per cent in 7½ hr. at vacuum at 2102 deg. F. At a temperature of 2225 deg. F., silicon efficiencies of 78 to 80 per cent were achieved in 7½ hr. at vacuum. Under optimum conditions, comparable efficiences were reached with dry-process briquets.

Dry briquets were normally charged cold and were weighed out and charged in paper bags to facilitate handling and to avoid breakage. The retorts were left open for 15 to 25 min. prior to evacuation to burn the paper bags and any oil adhering to the briquets. Vacuums of 200 to 250 microns of mercury in 1 to 1½ hr. and final vacuums of 50 to 100 microns were considered to be satisfactory. These conditions were not obtained unless the briquets were low in carbon dioxide and water and the vacuum pumps in good operating condition.

From tests made in a special laboratory furnace it was found necessary to maintain a vacuum of 0.1 to 0.3 mm. in order to obtain a dense metal deposit in the condenser. With increased pressure the condensed metal becomes more porous, with the resultant tendency to burn and with increased losses during the subsequent melting step.

Many materials were tested in the laboratory reduction apparatus to determine whether their inclusion in the calcine-ferrosilicon mix might catalyze the magnesium reduction reaction. Of those tried only CaF_2 and MgF_2 showed catalytic effects. The addition of fluorspar up to 5 per cent substantially increased the magnesium yield.

Laboratory tests with aluminum powder, aluminum-silicon alloys and various aluminum scrap confirmed the advantage of aluminum over silicon as a reducing agent, as to temperature and time.

To get good magnesium deposits there must be good vacuum, freedom of the briquetted charge from volatiles like water and carbon dioxide, and good separation of the alkali metals which are contained in various amounts in the dolomite.

Vacuum Engineering:

THROUGH the use of high vacuum, the distillation or sublimation of many reactive metals such as magnesium can be done industrially at much lower temperatures, and hence in much simpler equipment, than was heretofore thought possible, W. B. Humes, director of research and development, reported in "Vacuum Engineering as Related to the Dolomite Ferrosilicon Process."

The main function of vacuum in the ferrosilicon process and hence in most vacuum smelting processes is to lower the temperature at which the metal may be rapidly distilled or sublimed from the reduction mixture. A secondary function is to protect the newly produced metal from attack by the furnace atmosphere and to permit the formation of a dense condensate.

In the ferrosilicon process, the metal is produced from a briquetted charge at a free air pressure of about 0.100 mm. (100 μ) of mercury. This low pressure is not needed for the reaction but rather serves to protect the metal vapor from the oxygen or nitrogen of the atmosphere and permits the formation of a dense condensate relatively free from sodium.

However, at pressures above 500 μ the metal yield begins to decline. This does not necessarily mean that the reaction is impeded by the high pressure. It may be that the magnesium vapor oxidizes upon formation and thus remains in the charge. Sight gas observations confirm the fact that actual burning of deposited magnesium occurs at pressures as low as 100 μ (1.0 mm.).

The effect of pressure upon the quality of the condensate has been clearly demonstrated. At pressures above 500 μ, a deposit containing relatively large quantities of oxide, nitride and pyrophoric dust is formed. If sodium and potassium are present, as in the case of most dolomites, these metals usually burst into flame and ignite the pyrophoric magnesium during the discharging of the retort. At lower pressures, a dense metallic crown is formed, low in impurities and difficult to ignite.

It has been found in plants using the ferrosilicon process that the economical temperature for alloy retorts is about 2150 deg. F. and that an 8-hr. cycle is optimum. Under these conditions, it is desirable to maintain an operating pressure of 100 μ or lower and to reach that pressure within 1 hr. from the time of charging. Vacuum pumps perform two functions: (1) To provide for the initial evacuation in which large volumes of gas are produced at relatively high pressures, and (2) supply pumping speed at low pressures for the remainder of the cycle.

During the construction of the magnesium plants, industrial diffusion pumps using both oil and mercury were developed for the process. These pumps, which have extremely large

gas handling capacities at pressures below 100 μ, must be used in combination with a suitable backing pump, such as a rotary mechanical pump. Steam jet ejectors have been employed successfully in one plant which used a small number of very large retorts. A long evacuation cycle plus the large unit vacuum system makes steam jet ejectors particularly applicable in this installation. When suitable protective devices are available, it is possible that they will receive wider use. It is probable that for future operations, various combinations of these three pumping means will be evaluated to provide maximum efficiency.

Most ferrosilicon process plants have used retorts 8 ft. long and 10 in. i.d., making a volume including the condenser space of about 6 cu. ft. Four of these retorts are connected to a manifold and operated as a unit. The time necessary to evacuate this volume is given by the equation:

$$T = \frac{VK}{D}$$

where T is the evacuation time, V the volume of the system, D the pump displacement in cu. ft. a min., and K a constant depending upon the desired pressure.

In the ferrosilicon process the evacuation time is approximately 2 min. since

$V = 24$ cu. ft.
$K = 8$ for .100 mm.
$D = 100$ cu. ft. a min.

Actually this condition is realized only when there is no impedance in the pipe lines between the vacuum system and the pump and no leakage or outgassing. In actual plant operations this has not been feasible and in many cases the pumps are placed at different levels from the retorts necessitating pipe lines approximately 50 ft. in length. It has been calculated that when pumps with high capacities in the lower range be used, either the pumps must be placed close to the retorts or large pipes must be used.

Although piping carries only a relatively small external pressure, it must be made extremely non-porous because of the tremendous expanded volume of a small leak at atmospheric pressure. Considerations of the leakage problem led to the use of welded piping and forged steel fittings. Threaded joints are treated with resins paints like "Glyptal." Rubber or composition gaskets are cleaned and wet with grease and oil before assembly. Lubricated plug valves, up to 6-in. pipe size, have been used with success, although care must be exercised with regard to the lubrication and the condition of the valve seat surfaces.

It has been found that new piping systems are best subjected to an initial pressure and "soap bubble" test, and that final tests can be made under vacuum. Where thermocouple gages are used, vacuum leaks may be detected by spraying the suspected point with autone or other volatile liquid or hydrogen. As the vapor or hydrogen leak replaces the air leak, rise in pressure is noted on the gage.

Basic Magnesium Enterprise

THE combination of electric power from the Boulder Dam, water from Lake Mean and magnesite ore in Gabbs Valley led to the initial proposal to erect a magnesium reduction plant in southern Nevada.

The process used by Basic Magnesium to extract the metal from the ore is the electrolytic reduction of magnesite, developed initially by the I. G. Farbenindustrie and operated extensively in England by Magnesium Elektron Ltd. of Manchester, C. J. Ball, chairman of the board, Magnesium Elektron, Ltd., England and vice-president Basic Magnesium, Inc., revealed.

The first stage in the reduction process consists of the preparation of the raw materials. The magnesite materials are finely milled and then mixed with certain proportions of coal and of peat moss. The peat is added to give porosity to the pellets and to provide for the more rapid action of the chlorine upon the magnesium oxide content. Magnesium chloride solution made in the recovery and neutralization plant is added as a binder. The mix is then briquetted and dried, and coked in oil heated rotary kilns. The coked briquets are then fed into a shaft furnace or reaction tower lined with special refractory bricks and heated internally using carbon resistors and electrodes. The solid charge rests upon a network of carbon blocks which are heated by their resistance to the passage of 3 phase a.c. As the briquets pass from top to bottom of the reaction tower or chlorinator, which operates at a temperature around 1832 deg. F., they meet a stream of chlorine rising from the bottom of the furnace. The carbon in the briquets acts as a reducing agent and the magnesium oxide is converted to absolutely anhydrous magnesium chloride.

The fused chloride is tapped periodically from the bottom of the reaction tower and fed into special electrolytic cells. Chlorination and electrolysis take place in one building in which, for the purpose of easy tapping and feeding to the cells, the chlorinators are located in a line along one side of the cell room. The exhaust gases from the chlorinators are washed and the resultant hydrochloric acid solution concentrated, clarified and neutralized with magnesium oxide to provide magnesium chloride solution used in the process.

Each unit contains eight chlorinators and 88 cells, the latter built in eight banks, each of 11 cells, with a capacity of 5600 tons a year.

Electrolysis of the fused magnesium chloride is carried out in electrolytic cells lined with refractory and insulating bricks to take care of the comparatively high working temperature. The electrolytic consists of a salt mixture which inhibits the tendency of anhydrous magnesium chloride to decompose when molten and favorably influences the conductivity, viscosity and specific gravity of the electrolyte.

Provision of electrode surfaces of maximum area and the maintenance of a fixed ratio between the depth of immersion of electrodes and their distance are essential combinations of maximum economy.

The cells are so designed as to allow the separation and collection of the chlorine by use of ceramic curtain walls of high density and of particular properties forming a part of the cell and built in between the parallel electrodes.

Cast steel cathodes and graphite anodes are used. The chlorine which is quite dry and concentrated, collects in the anode compartment, and is drawn off, filtered and recirculated to the chlorinators.

The cell is not externally heated, the electrical input of about 20,000 amp. being sufficient to maintain the temperature of the charge. The power consumption is approximately 9 kw.-hr. per lb. of metal. The magnesium metal collects at the cathode, floats to the surface of the melt and is dipped out every 24 hr.
